Roofing paper for agricultural purposes. ANON. *Teer* 24, 19-22(1926).—A review of expts. on the use of roofing paper, both tarred and tar-free, for the protection of crops during their early development. Results are given for a no. of different vegetables. Large increases in the crops obtained are noted. W. B. PLUMMER

Production of fertilizer material. ANON. *Meddl. Sveriges Kem. Ind.-kontor* 8, 124-6(1925).—The world's production of fertilizers for 1913, 1921, -22, -23 and -24 are tabulated for raw phosphate, superphosphate, Thomas slag, potash, Chili saltpeter, Norway saltpeter, CaCN_2 , and $(\text{NH}_4)_2\text{SO}_4$. The amounts are 1000 metric tons. A. R. ROSE

The physiological reaction of fertilizer salts. H. KAPPEN AND M. LUKACS. *Z. Pflanzenernähr. Düngung* 5A, 249-71(1925).—Expts. with nitrates and with NH_4 salts in water cultures with different plants again substantiated the physiol. reaction of these salts. NH_4NO_3 was physiol. acid under some conditions and physiol. alk. under other. The growth of corn, mustard and buckwheat produced the same reaction in physiol. alk. solns., but these varied in their effects on physiol. acid solns.; corn produced the most acid condition, and mustard the least. Corn grown in neutral glass sand produced an acid reaction in both solns. contg. NH_4 salts and nitrates after $4\frac{1}{2}$ weeks. Studies on the course of the reaction change showed that the physiol. alk. solns. changed their reaction slowly; while physiol. acid solns. changed rapidly. An arrangement by which the H-ion concn. of the nutrient solns. might be measured without disturbing the solns. was devised by immersing the electrode in the culture vessel and by using a Pt connection to the calomel half-cell. A standard deviation from the usual arrangement was noted and a correction applied. When the nitrate or NH_4 salts solns. were sepd. from the other nutrients and part of the root system was grown in each, the single salt (i. e. nitrate or NH_4) changed in H-ion concn. while that of the soln. contg. the other nutrients remained about const. A theoretical discussion of the absorption processes in plants is given. R. M. BARNETTE

Results with artificial fertilizers on cultivated plants in Java and Madura. A. WULFF. *Arch. Suikerind.* **33**, 1301-22(1925).—A summary is presented of the results of fertilizer tests made since 1911, mostly on rice, but including a few expts. on maize, tobacco, etc. P has been found beneficial, N has given good results as a top dressing in some cases; but K has rarely increased yields. Finally ground rock phosphate has been found useful on certain laterite soils. F. W. ZERBAN

Nitrogenous fertilizers in flax culture. M. GROHS. *Faserforschung* **5**, 37-51 (1925).—A no. of test plots were suitably prepd. to demonstrate the effect of N fertilizers on the flax produced, and to compare the efficiency of various sources of N. In general, N favors the products not considered valuable in fiber flax cultivation. The seed yield is increased under comparable conditions, but there is also an increase in the scutching waste, and a very serious decrease in the quality and strength of the fiber. Very evidently, K and PO_4 are more valuable for fiber flax. The rank growth obtained with Chili saltpeter was remarkable considering the dryness of the season, but the fiber was so weak comparatively that nitrate N is considered inadvisable. Cyanamide not only gave but little evidence of promoting the desirable effects of N fertilizing, but produced poor fiber. $(\text{NH}_4)_2\text{SO}_4$ gave the best results, all things considered. E. R. CLARK

Trials with artificial farmyard manure at Lincoln. M. J. SCOTT. *New Zealand J. Agr.* **31**, 256(1925).—Inconclusive results were obtained in expts on mangolds with artificial manure. K. D JACOB

Colloidal silica and the efficiency of phosphates. P. L. GILE AND J. G. SMITH. *J. Agr. Research* **31**, 217-60(1925). The addition of silica gel to millet grown in sand culture greatly increased the growth of plants supplied with rock phosphate and only slightly increased those supplied with acid phosphate. The addition of a mixed gel contg. Fe, Al and SiO_2 to a pot receiving rock phosphate was marked by reduced growth as compared with the growth made in pots receiving no P_2O_5 . Growth made by the plants was approx. proportional to the quantities of P_2O_5 in the plants, but seemed to bear no relation to the quantities of SiO taken up. The beneficial action of silica gel on the growth of plants supplied with rock phosphate is ascribed to the increasing of the availability of this phosphate through increasing the quantity of P_2O_5 in soln., and the deleterious effect of the mixed gel to a diminishing of the quantity of P_2O_5 in soln. owing to sol. Fe and Al produced by base exchange. This conclusion was substantiated by the quantities of P_2O_5 found in soln. on shaking up rock phosphate with silica gel and with a nutrient soln. such as was used in the pot expt. The relation of the action of silica gel on the efficiency of phosphates to that of the soil colloidal material is discussed. A bibliography of 40 references is appended. W. H. ROSS

Experiments on fertilization of rape in Canterbury. F. E. WARD. *New Zealand J. Agr.* **31**, 308-11(1925).—Mixts. of superphosphate and Ephos basic phosphate gave as high yields as superphosphate alone. Superphosphate gave much better results than Ephos basic phosphate during the first 8 weeks of growth but somewhat better results were obtained with the latter after 13 weeks. As compared with superphosphate, Ephos basic phosphate delayed ripening of the rape. Addn. of dried blood to the superphosphate increased the yields in all cases. K. D JACOB

The quality and yield of tobacco as influenced by fertilizing and other operations. J. N. MUKERJI. Mem. Dept. Agr. India, *Chem. Series* **8**, 1-26(1925).—Superphosphate or salt pter used singly is not effective as a fertilizer for tobacco in Pusa soil. A complete mineral fertilizer such as superphosphate, NaNO_3 and KCl gives excellent results. The presence of K_2O in the fertilizer has regularly increased the yield. The greatest total yield is produced by a fertilizer contg. relatively more P_2O_5 in proportion to N than is found in manure. Manure or indigo seeth is the best fertilizer for tobacco in Bihar on account of cheapness, availability and effectiveness. The ash, amino N and albuminoid N, constituents which have a bearing on the quality of tobacco, are hardly affected by different fertilizing treatments. Inorg fertilizers generally give a higher, and org. a lower K_2O content. KCl increases the Cl content, which injures the burning quality of tobacco. A comparison of topping and spiking the tobacco plants shows that topping improves the quality while the yield by both operations is almost identical. Studies on tobacco curing have shown that rack-curing produces a tobacco of a bright yellow color suitable for cigaret manuf., while ground-curing produces tobacco of a dark brown hue. Rack-cured leaves possess greater elasticity than ground-cured leaves. Rack-curing produces a tobacco of lower nicotine and higher starch content than ground-curing. RUSSELL M. JONES

Experiments on the control of wildfire of tobacco. J. JOHNSON AND H. F. MURWIN. Wisconsin Agr. Expt Sta., *Res. Bull.* **62**, 34 pp.(1925).—Wildfire infection of tobacco

occurs in the seed bed. Seeds are successfully disinfected by treatment with a 0.01% AgNO_3 soln. for 2 periods of 5 to 10 min. each. Cu-lime dust and Bordeaux mixts. reduce the amt. of infection in seed beds, but not sufficiently materially to reduce the amt. of subsequent field infection if conditions for its spread are favorable. The wild-fire bacteria produce a toxin in host tissue and in culture which is responsible for the chlorosis produced in plant tissue. The toxin is readily sepd. from the bacteria by filtration and will in itself produce typical symptoms by inoculation. J. J. SKINNER

Observations on the degree of solubility of phosphate and potash fertilizers. ROMUALDO AVATTANEO. *Rass. min. met. chim.* **63**, 140-1 (1925).—Great stress is laid on the lack of economy in the use of potash and phosphate compds. of too high soly. in H_2O , both because of the cost and of the unfavorable action. The most economical fertilizer for Italy is a mixt. of a natural phosphate and leucite, which will maintain nearly const. concns. of sol. phosphate and K salt favorable to the plant. Also in *Proc. Internat. Soc. Soil Science* [N. S.] **1**, 157-60 (1925) C. C. DAVIS

The action of copper compounds on the smut spores of wheat. J. BODNÁR AND ALEXANDER TERÉNYI. *Chem.-Ztg.* **49**, 902 (1925).— CuSO_4 does not kill the smut spores, but hinders their germination. The quantity of Cu absorbed by the spores from weak solns. of CuSO_4 , $\text{Cu}(\text{NO}_3)_2$ and CuCl_2 of various concns. is about the same; but the amt. absorbed is greater in solns. of $\text{Cu}(\text{OAc})_2$. Spores treated with CuSO_4 will not germinate in water, but if the Cu absorbed is leached out with dil. HCl or moisture in the ground, germination ensues. The retardation of the germination of the Cu-treated spores in the earth is proportional to the quantity of the Cu absorbed. If 9 mg. of spores (3,600,000) is contained in 10 cc. $\text{Ca}(\text{NO}_3)_2$ nutrient soln. contg. 0.001% of Cu as CuSO_4 , no germination takes place. If the soln. contains 0.0001% of Cu, germination is only retarded; while a soln. of 0.00001% of Cu has no effect upon the spores. GEO. R. BANCROFT

New seed disinfectants for the control of bunt of wheat and the smut of oats and barley. W. H. TISDALE, J. W. TAYLOR, R. W. LEUKEL AND M. A. GRIFFITHS. *Phytopathology* **15**, 651-76 (1925).—Greenhouse and field-plot expts. extending over 4 yrs. and employing a large number of the newer seed disinfectants, especially Hg compds., are reported. Naturally infested seed was employed insofar as possible, but all lots were heavily inoculated prior to treatment. Cu carbonate gave good control of bunt and improved the stand and yield of wheat, but did not satisfactorily control oat and barley smuts. None of the dust treatments thus far proposed controls these smuts satisfactorily. In liquid treatment, a number of the org. Hg compds. gave excellent results in controlling barley smuts and less satisfactory, but fairly good control of oat smut. The effectiveness was equal to that of CH_4O , there was no injury, and stimulation of growth was very evident. Furfural injured barley seed and permitted higher percentages of smut than in the controls. JOSEPH S. CALDWELL

Potassium xanthate as a soil fumigant. E. R. DEONG. *Ind. Eng. Chem.* **18**, 52-5 (1926).—K xanthate and Na xanthate change in an acid medium to xanthic acid, which at moderate temps. decomposes into CS_2 and alc. K xanthate on account of its soly. in H_2O may be distributed in the soil at any convenient depth and at any concn. This makes possible the treatment of soils at a lower concn. of CS_2 than is possible where the latter is used pure. By this means a uniform dosage may be distributed through large bodies of soil and with less danger to the living plant. Combining K xanthate with varying proportions of $\text{CaH}_4(\text{PO}_4)_2$, $\text{Fe}(\text{NO}_3)_3$, or S will give a variable rate of release of xanthic acid, depending on the proportion of the chemicals used and the soil medium. This offers the possibility of an immediate fumigating action followed by a slow release over a period of days or possibly weeks with varying concns. of CS_2 . This is being tried as a means of controlling the root knot nematode which in its encysted form is very difficult to kill with chemicals. J. J. SKINNER

Use of spreaders with Bordeaux mixture. H. L. MANUEL. *Agr. Gaz. N. S. Wales* **36**, 702 (1925).—Resin fish oil soap and casein were equally effective as spreaders for Bordeaux mixt. on grape vines. K. D. JACOB

Chemical control of weeds and its limitations. D. H. ROBINSON. *Fertilizer, Feeding-Stocks and Farm Supplies J.* **10**, 982-3 (1925); cf. *C. A.* **20**, 88.—The ease with which weeds may be controlled by chem. means, particularly spraying, is largely dependent on their specific botanical characteristics. K. D. JACOB

Sheep blow-fly control: a new method. BERNARD SMIT. *J. Dept. Agr. Union S. Africa* **11**, 455-8 (1925).—Dead sheep were placed in holes covered with heavy wire netting and after 2 days the carcasses were lightly sprayed each morning with a soln. contg. 2 ounces of Na_3AsO_3 per gallon. Practically all of the maggots were killed after 6 days but the adult flies seemed to be little affected. Decompn. had ceased by this

time because of the preservative action of the arsenite and flies were no longer attracted to the carcasses. Addn. of sugar did not increase the effectiveness of the poison. A new method of control not involving the use of poisons is described. K. D. JACOB

Experiments on means for combating the beet fly. HANS BREMER. *Deut. Zuck-erind.* 50, 1389-91(1925). W. L. BADGER

Calcium cyanide. THEODORE PARKER. *Fertilizer, Feeding-Stuffs and Farm Supplies J.* 10, 915(1925).—Complete control of white and green flies in hot houses was obtained with $\text{Ca}(\text{CN})_2$ used at the rate of 0.25 to 0.33 ounce per 1000 cu. ft. at a temp. of 60-70° F. In order to obtain its max. effect the air must contain sufficient moisture to decompose the $\text{Ca}(\text{CN})_2$. K. D. JACOB

Chemical investigations in regard to citrus (JURITZ) 11D. The chemistry of CaCN_2 (FRANCK, HOCHWALD) 2.

RIVS Y MIRO, ANTONIO: *Cianamida cálcica*. Madrid: Calpe. 207 pp. Ptas 6.

Destroying insects by fumigation. R. C. ROARK. *Brit.* 234,456, May 26, 1924. EtOAc is used (preferably with $1\frac{1}{2}$ times as much CCl_4) for fumigating grain, etc. to destroy weevils or insects.

Insecticides. I. McDougall and F. Howles. *Brit.* 233,857, April 15, 1924. Insecticidal powders for treating plants comprise nicotine, powd. *Derris* root or *Derris* ext. and an inert material such as CaCO_3 or CaSO_4 .

Dry disinfectant for seed. O. G. JOHANSSON. *Swed.* 59,798, Nov. 3, 1925. A dry mixt. of CuCO_3 and Hg compds. with or without addn. of CaCO_3 .

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Differentiation of abnormal wines from watered wines. FONZES-DIACON. *Ann. fals.* 18, 606-7(1925); cf. following abstr.—Analyses previously published by Aubouy of wines known to be abnormal conform with the rules given by F.-D. A. P.-C.

Abnormal wines: differentiation from watered wines: tartar number. FONZES-DIACON. *Ann. fals.* 18, 532-6(1925).—The "tartar no." is defined as the ratio of the total tartaric acid to the total K_2O , both expressed as K bitartrate. A wine may be considered as natural but abnormal when: fixed acidity (in g. per l.) + alc. (% by vol.) is less than 12, tartar no. < 1, total K_2O (as K bitartrate) < 4, and volatile acidity < 0.70. A wine may be considered as accidentally abnormal (through disease) when: fixed acidity + alc. is less than 12, tartar no. < 1, total K_2O (as K bitartrate) < 4, volatile acidity < 1. A. PAPINEAU-COUTURE

Wines of the coöperative wine cellars of the Bas-Rhône region (France). H. ASTRUC AND G. CHEVALIER. *Ann. fals.* 18, 536-46(1925).—Analyses of 71 wines of the 1923 and 1924 vintages are tabulated and commented. A. PAPINEAU-COUTURE

New method for the approximate determination of moisture in malts. L. FRIES. *Schweiz. Brauer Rundschau* 1925, 153; *Bull. assoc. inst. sup. fermentations Gand* 27; *Ann. soc. brasseurs* 35, 38(1926).—The method is based on the rise in temp. which takes place on mixing finely ground malt with water, and is carried out as follows: finely grind the malt under conditions which prevent rise in temp., place 100 g. of malt and 160 cc. H_2O in sep. covered containers in a water bath at room temp., allow to stand 3-4 hrs., pour the H_2O on the malt flour, stir with a wooden spatula for 1 min., and note the temp. to 0.1°. A rise in temp. of 2°, 3°, 4°, 5°, 6° and 7° corresponds to 8.6, 6.5, 5.0, 3.6, 2.4 and 1.4% H_2O , resp. The results agree to within 0.5% with those obtained by the usual methods. A. PAPINEAU-COUTURE

Use of aluminium in breweries. ALB. MERTENS. *Bull. assoc. école sup. brasserie Louvain* 26, 34-44(1926).—A discussion of the qualities required of com. Al for it to be suitable for use in breweries. A. PAPINEAU-COUTURE

The volutin in yeast cells. M. GLAUBITZ. *Z. Spiritusind.* 48, 363(1925).—A good yeast usually has a fairly high protein as well as high phosphate content. Volutin, a protein substance probably existing in the form of little droplets in the cells, was investigated to det. if any relation existed between volutin content and fermentative activity. No positive relation was found, for when 1 or 80% of the cells contained volutin the rate of fermentation was nearly the same. The content of volutin diminishes during storage. C. N. FREY

Chemical principles in vinegar investigation. ERICH WALTER. *Deut. Essigind.* 29, 460-1 (1925). W. O. E.

Review of the progress in making fermented vinegar. PAUL HASSACK. *Fruit Products J. and Am. Vinegar Ind.* 4, No. 10, 15-6; No. 11, 15-7 and 19; No. 12, 15-8; 5, No. 1, 14-8; No. 2, 13-5 (1925). J. A. KENNEDY

Formic acid in vinegar. H. MOHR. *Deut. Essigind.* 29, 469 (1925).—In the course of a large no. of investigations during the years 1912-14 the amt. of CH_2O_2 in vinegar and triple vinegar was shown to be appreciably less than 0.5 g. per 100 g. $\text{C}_2\text{H}_4\text{O}_2$. Recent examns. have, however, yielded relatively greater amts. of CH_2O_2 . Of 45 samples examd., 12 contained the following amts. of CH_2O_2 : 0.294, 0.44, 0.448, 5.494, 0.46, 0.50, 0.55, 0.56, 0.655, 0.25, 0.364, 0.572 in 100 total acid. It is reported from a competent source that com. 80% acetic acid contains an av. of 0.2% CH_2O_2 , an amt. in excess of that legally permitted. W. O. E.

Regarding dried-apple vinegar. R. O. BROOKS. *Fruit Products J. and Am. Vinegar Ind.* 4, No. 11, 13-4 (1925).—This is a discussion of the "notice of Judgment 12,367." J. A. KENNEDY

Generator size and optimum temperature for vinegar bacteria. H. WÜSTENFELD. *Deut. Essigind.* 29, 375-6 (1926).—To achieve max. efficiency in the production of acid in generators development of various types of bacteria would be necessary for different sized generators, each type having an optimum rate of oxidation at a different temp. level, degree of acidity and concn. of wort. The interior of a large generator with insufficient radiation reaches a higher temp. at a slower rate of oxidation and heat production than a small one. Consequently the temp. is not an index of the efficiency or rate of oxidation. As rapidly as the temp. in a com. generator reaches limits above the optimum, the rate of oxidation changes and the temp. falls. Because of this automatic regulation there is no period during which a temp. much above the optimum exists. C. N. FREY

The nipa palm as a source of sugar and alcohol (REIJGERSBERGH) 28.

Lactic acid. S. E. FAITHFULL. U. S. 1,569,221, Jan. 12. During the production of lactic acid by fermentation of solns. contg. glucose or similar carbohydrate material, air or O is injected to inhibit formation of butyric acid. Pb lactate may be used for pptg. proteins and similar substances from the resulting soln. and residual carbohydrate material in the lactate soln. produced may be caramelized and the soln. then decolorized with active C.

Aldehydes from cacti. W. M. SINCLAIR. U. S. 1,569,339, Jan. 12. Cacti are mashed without addn. of H_2O under conditions favorable to fermentation by indigenous fungous material, the fully fermented pulp is hydrolyzed, subjected to distn. and aldehyde material and essential oil are condensed and sepd. The product is suitable for alc. production.

Yeast. VEREINIGTE MAUTNER'SCHE PRESSHEFE-FABRIKEN GES. Brit. 234,843, May 30, 1924. Molasses for yeast production is purified without destruction of the vitamins by diln. and filtration. An inert powder may be added, e. g., talc with acid molasses and chalk with alk. molasses. The molasses may be subjected to lactic fermentation before filtration, to render the protein content available and the N content may be further increased by adding sepd. white of egg and NH_3 or NH_4 salts.

Preserving yeast. U. WEGENER. U. S. 1,570,418, Jan. 19. Yeast is embedded in a finely cryst. mass of invert sugar.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Myrrhis odorata Scop. and the microchemical detection of anisic acid. L. VAN ITALLIE AND A. J. STRENNHAUER. *Pharm. Weekblad* 63, 4-7 (1926).—*Myrrhis odorata* contains a volatile oil which consists chiefly of anethole. The distillate contains also MeAc and MeOH and the residue fumaric acid and sucrose. Anisic acid, obtained by oxidation of the anethole with CrO_3 , may be identified microchemically by the formation of Ag, Ca, Ba and Sr salts. A. W. DOX

Perfumes for vanishing creams. WM. A. POUCHER. *Am. Perfumer* 20, 511-2 (1925).—Among the topics discussed are: prerequisites for a good perfume, volatile solvent process, modern apph, volatile oil perfumes, synthetics and natural isolates, resinous substances and blending the perfumes. W. O. E.

Albumose silver. C. MANNICH AND K. CURTAZ. *Arch. Pharm.* **263**, 669-74 (1925).—A comparative study was made of 6 different brands of *Argentum proteicum* (including protargol) with respect to their behavior toward an ultrafilter of collodion membrane, 0.25% solns. of the sample being subjected to filtration over a period of 15 hrs., thereby yielding a filtrate of about 10 cc. All filtrates were colorless, although in the light they rapidly became discolored; they contained furthermore Ag and protein material. The Ag content of the ultrafiltrates was in every case less than that of the original soln., amounting to 10-40% of the unfiltered liquid, so that 60-90% of the Ag remained behind. A portion of the Ag loss is due to adsorption by the membrane. While the differences observed in Ag content of the several filtrates are probably outside the error limits of the method, they are not so marked as to permit the assumption that the degree of dispersion of the Ag is essentially different in the several brands. It is concluded, therefore, contrary to the findings of Utz (cf. *C. A.* **18**, 3101) that the degree of Ag dispersion in protargol is deserving of no special consideration. W. O. E.

Notes on bismuth compounds. II. ERNST MASCHMANN. *Arch. Pharm.* **263**, 721-6 (1925); cf. *C. A.* **19**, 1515.—As elaboration to the first communication, a chemotherapeutic study has been made of certain substances contg. As and Bi in the mol., as also a compd. involving the 3 parasitocidal elements As, Hg and Bi. The following compds. were prepd. for purposes of this study: *basic Bi salt of 3-amino-4-hydroxybenzenearsonic acid*, $C_6H_7O_6NAsBi$, ppt. insol. in H_2O and org. media; *basic Bi salt of 3-acetylaminio-4-hydroxy-5-hydroxymercuribenzenearsonic acid*, $C_8H_9O_7NAsBiHg$, ppt. insol. in H_2O ; *complex Bi compd. of 3-dihydroxypropylamino-4-hydroxybenzenearsonic acid*, sol. in H_2O , insol. in Et_2O and $MeOH$; *bismuthyl deriv. of di-Na o-(β -carboxy- α,β -dihydroxyethyl)benzoate*, $C_{10}H_7O_7BiNa_2$, insol. in alc. and Et_2O ; *complex Bi compd. of caffeic acid*, $C_9H_6O_6BiNa$; *complex Bi compd. of alizarin*, $C_{14}H_7O_6Bi$; *complex Bi salt of Na 7-iodo-8-hydroxyquinoline-5-sulfonate*, $C_{17}H_{12}O_2NaI_2BiNa_3$. W. O. E.

Preparation, properties, application and testing of antiseptics. T. H. FAIRBROTHER AND A. RENSHAW. *Ind. Chemist* **1**, 419-21 (1925).—In the 1st instalment of their paper the authors deal with the first 3 of the headings; in the final part the various methods of testing the antiseptic value of the several compds. are dealt with very thoroughly. An attempt has been made to show how modern methods have developed from the early efforts of Lister. First of all there was the trial-and-error method applied to all possible substances which might possess antiseptic properties. This slowly changed with the development of chemotherapy into an organized attack on parasites by the synthesizing of chem. mols. showing selective action. For general purposes of sanitation and disinfection the old coal-tar fluids have their uses, but this is only the fringe of the problem of antiseptic action. The main function of an antiseptic is to prevent the growth of organisms upon tissues of fabrics without damage thereto. The most critical application of this is, of course, in relation to human tissues. Progress in this direction must be made by the synthesis of further substances in the light of present knowledge. The pioneer work of Lister, Pasteur, Ehrlich and others showed that definite groupings and mol. configurations bring about antiseptic action and this foundation must be built upon by present-day investigators. W. O. E.

Vanillin, piperonal and coumarin. L. G. RADCLIFFE AND F. H. SHARPLES. *Perfumery Essent. Oil Rec.* **15**, 396-402, 437-9 (1924); **16**, 20-3, 51-3, 87-92, 156-62, 197-9, 271, 353-5, 387-90 (1925).—The present research had for its object an examn. of the various recognized methods of estn. In addn. to an extensive bibliography it presents in 2 parts the recognized methods for the estn. of vanillin and piperonal separately, gravimetric, volumetric and colorimetric methods, methods for the estn. of vanillin in the presence of piperonal, methods for the estn. of coumarin, examn. of the properties of vanillin, piperonal and coumarin with a view to the establishment of new methods as (1) vanillin in presence of piperonal and coumarin, (2) vanillin or piperonal, (3) coumarin in presence of vanillin and piperonal and (4) coumarin alone. W. O. E.

Biological evaluation of drugs. F. KNAFFL. *Pharm. Monatshefte* **6**, 209-15 (1925).—An address. W. O. E.

Cultivation of drug plants. LUDWIG KROEBER. *Pharm. Ztg.* **70**, 1738-9 (1925).—The personal experience of the author is briefly described in cultural expts. with plants like marsh mallow, valerian, Chinese rhubarb, peppermint, digitalis, stramonium, thyme, mullein, fennel, mustard, etc. W. O. E.

Action of *Matricaria discoidea* and *M. chamomilla*. C. G. SANTESSON. *Pharm. Zentralhalle* **66**, 829-31 (1925).—Comparative expts. on the action of these 2 drugs develop no essential difference in their behavior. W. O. E.

Colloid salve therapy and colloid cosmetics. L. ZAKARIAS. *Pharm. Zentralhalle* **66**, 831-2 (1925).—Certain advantages are claimed and discussed for the new therapy,

notably in that they do not hinder the natural and pathological secretion of the skin and possess furthermore a considerably greater covering capacity than ordinary H_2O -sol. salves. W. O. E.

The extraction of oil of lemon. A. A. RAMSAY. *Agr. Gaz. N. S. Wales* **36**, 705 (1925).—A note on the methods. K. D. JACOB

Investigation on Indian opium. IV. Further experiments on the influence of fertilizers on the yield and morphine content of the latex from the opium poppy. H. E. ANNETT AND H. D. SINGH. *Mem. Dept. Agr. India*, Chem. Series **8**, 27-37 (1925); cf. *C. A.* **15**, 248; **16**, 1484; **17**, 2767.—Org. fertilizers such as cakes and cattle manure in addition to giving an increased yield of opium appear to produce an increase in its morphine content. The increased morphine content does not seem to be brought about by the N or K_2O supplied by the fertilizer but rather by the P_2O_5 . **V. Experiments on oil content of the seed of the opium poppy.** H. E. ANNETT AND M. N. BOSE. *Ibid* **39**-43.—The oil content of the seed of the opium poppy as grown in the United Provinces seems to be remarkably const. There are very small differences in the oil content of the seed of 9 pure races tested. There is no marked effect due to season, climate or fertilizers tested. The terminal and lateral capsules appear to produce seed of the same oil content. The process of lancing the capsules for opium has no effect on the oil content of the seed. **VI. Studies on the ash constituents of Indian opium.** H. E. ANNETT AND M. N. BOSE. *Ibid* **45**-51.—There is a steady rise in the amt. of ash constituents of the latex of the opium poppy at each successive lancing up to the fourth, after which no increase appears. The compn. of the ash appears to be the same in each successive lancing and is not appreciably affected by fertilizing. SO_3 and P_2O_5 detd. in the original opium increase rapidly in the first three lancements, the P_2O_5 increasing up to the fifth lancing. Cl is not present in the latex. The increase in ash constituents of each successive lancing is accompanied by a rapid falling off in total alkaloid content of the latex. This is accounted for by the rapid fall in morphine and to a lesser extent by the fall in narcotine content. Codeine and papaverine are present in more or less const. amts. in each successive lancing. It is possible that there is a physiol. connection between the rise in ash constituents and the fall in morphine. R. M. J.

Investigations of essential oils. ANON. *Bull. Imp. Inst.* **23**, 421-9 (1925).—*Camphor leaves and twigs* from Uganda, contg. 11.8% H_2O , yielded on steam distn. 2.3% of oil or about 1.8% solid camphor. Two samples of *Massoi bark* (*Cinnamomum Massoia*, Schewe) from Papua yielded on steam distn. 6.0% and 6.3% of oil with: d_{15}^{15} 1.060, 1.064; $[\alpha]_D$ -0.90° , -0.34° ; n_D^{20} 1.534, 1.536; phenols (as eugenol) 60, 79%, resp. The approx. compn. of the 2nd sample was: eugenol 79, safrole 14, other constituents (mostly terpenes) 7%. The oil is similar to that obtained by previous investigators from "massoy" bark from New Guinea. *Oil of Origanum Maru* from Cyprus had: d_{15}^{15} 0.904, n_D^{20} 1.4775, $[\alpha]_D^{20}$ $+9.27^\circ$, acid value 4.1, ester value before acetylation 4.1, ester value after acetylation 74.5, oil absorbed by a 5% NaOH soln. 2.5%, sol. in 1.4 vols. 80% alc. at 15° . The const. are similar to those of *marjoram* oils previously received at the Imp. Inst. from Cyprus and of com. Spanish *marjoram* oils. *Medang losoh oil* distd. in the Federated Malay States from the wood of *Cinnamomum parthenoxylon*, Meissn., had: d_{15}^{15} 1.103, $[\alpha]_D$ nil, ester value before acetylation 0.8, ester value after acetylation 3.5, congealing point $+10^\circ$, sol. in 3.5 vols. of 90% alc. Distn. at 772 mm. gvc: 234-7° 91, 237-9° 5, residue 4%, showing the oil consists principally of *safrole*. A. PAPINEAU-COUTURE

Saffron. GEORGES PIERLOT. *Chimie et industrie* **14**, 839-50 (1925); cf. *C. A.* **30**, 263.—A monograph. *Oil of saffron* (obtained by steam distn. of the Et_2O ext.) had d_{15}^{15} 0.9514-0.9998, and a very slight *l*-rotatory power; it deposits rhombic crystals of a stearoptene m. 106° (recrystd. from a mixt. of Et_2O and petrole ether). Rectification of the oil *in vacuo* gives *sativol* (new), b_3 73° , b_3 69° , b_{760} 217° (corr.), d_{15} 0.9681, $[\alpha]_D$ 0, readily dehydrated to a mobile hydrocarbon, gives Denigès' reaction with $HgSO_4$, indicating that it is a tertiary alc. *Picrocrocine* recrystd. from $EtOAc$, m. 196° , showing that Kayser's product, m. 75° (*Ber.* **1884**, **1885**), must have been very impure. On hydrolysis it gives *sativol*, an uncrystallizable lactonic compd. which is apparently a phthalein, fructose and 1 mol. of HCO_2H . *Crocine* is best obtained by extn. with cold 70% $EtOH$ after extn. with Et_2O . It is next to impossible to obtain it entirely free from *picrocrocine*. *Croceline* is obtained by hydrolyzing *crocine* with dil. acids, filtering the red flocculent ppt., and recrystg. from Me_2CO or from $EtOAc$. Bibliography of 14 references. A. PAPINEAU-COUTURE

Essential oils in the Norwegian pharmacopea. GEORGES RENAUDET. *Parfumerie*

Albumose silver. C. MANNICH AND K. CURTAZ *Arch. Pharm.* **263**, 669-74 (1925).—A comparative study was made of 6 different brands of Argentum proteinicum (including protargol) with respect to their behavior toward an ultrafilter of collodion membrane, 0.25% solns. of the sample being subjected to filtration over a period of 15 hrs., thereby yielding a filtrate of about 10 cc. All filtrates were colorless, although in the light they rapidly became discolored; they contained furthermore Ag and protein material. The Ag content of the ultrafiltrates was in every case less than that of the original soln., amounting to 10-40% of the unfiltered liquid, so that 60-90% of the Ag remained behind. A portion of the Ag loss is due to adsorption by the membrane. While the differences observed in Ag content of the several filtrates are probably outside the error limits of the method, they are not so marked as to permit the assumption that the degree of dispersion of the Ag is essentially different in the several brands. It is concluded, therefore, contrary to the findings of Utz (cf. *C. A.* **18**, 3101) that the degree of Ag dispersion in protargol is deserving of no special consideration. W. O. E.

Notes on bismuth compounds. II. ERNST MASCHIMANN. *Arch. Pharm.* **263**, 721-6 (1925); cf. *C. A.* **19**, 1515. As elaboration to the first communication, a chemotherapeutic study has been made of certain substances contg. As and Bi in the mol., as also a compd. involving the 3 parasitocidal elements As, Hg and Bi. The following compds. were prepd. for purposes of this study: *basic Bi salt of 3-amino-4-hydroxybenzenearsonic acid*, $C_6H_7O_6NAsBi$, ppt. insol. in H_2O and org. media; *basic Bi salt of 3-acetyl amino-4-hydroxy-5-hydroxymercuribenzenearsonic acid*, $C_8H_9O_7NAsBiHg$, ppt. insol. in H_2O ; *complex Bi compd. of 3-dihydroxypropylamino-4-hydroxybenzenearsonic acid*, sol. in H_2O , insol. in Et_2O and $MeOH$; *bismuthyl deriv. of di-Na o-(β -carboxy- α,β -dihydroxyethyl)benzoate*, $C_{10}H_7O_6BiNa_2$, insol. in alc. and Et_2O ; *complex Bi compd. of caffeic acid*, $C_9H_6O_6BiNa$; *complex Bi compd. of alizarin*, $C_{14}H_7O_6Bi$; *complex Bi salt of Na 7-iodo-8-hydroxyquinoline-5-sulfonate*, $C_{17}H_{12}O_{12}NaI_2BiNa_3$. W. O. E.

Preparation, properties, application and testing of antiseptics. T. H. FAIRBROTHER AND A. RENSHAW. *Ind. Chemist* **1**, 419-21 (1925).—In the 1st instalment of their paper the authors deal with the first 3 of the headings; in the final part the various methods of testing the antiseptic value of the several compds. are dealt with very thoroughly. An attempt has been made to show how modern methods have developed from the early efforts of Lister. First of all there was the trial-and-error method applied to all possible substances which might possess antiseptic properties. This slowly changed with the development of chemotherapy into an organized attack on parasites by the synthesizing of chem. mols. showing selective action. For general purposes of sanitation and disinfection the old coal-tar fluids have their uses, but this is only the fringe of the problem of antiseptic action. The main function of an antiseptic is to prevent the growth of organisms upon tissues of fabrics without damage thereto. The most critical application of this is, of course, in relation to human tissues. Progress in this direction must be made by the synthesis of further substances in the light of present knowledge. The pioneer work of Lister, Pasteur, Ehrlich and others showed that definite groupings and mol. configurations bring about antiseptic action and this foundation must be built upon by present-day investigators. W. O. E.

Vanillin, piperonal and coumarin. L. G. RADCLIFFE AND E. H. SHARPLES. *Perfumery Essent. Oil Rec.* **15**, 396-402, 437-9 (1924); **16**, 20-3, 51-3, 87-92, 156-62, 197-9, 271, 353-5, 387-90 (1925).—The present research had for its object an examn. of the various recognized methods of estn. In addn. to an extensive bibliography it presents in 2 parts the recognized methods for the estn. of vanillin and piperonal separately, gravimetric, volumetric and colorimetric methods, methods for the estn. of vanillin in the presence of piperonal, methods for the estn. of coumarin, examn. of the properties of vanillin, piperonal and coumarin with a view to the establishment of new methods as (1) vanillin in presence of piperonal and coumarin, (2) vanillin or piperonal, (3) coumarin in presence of vanillin and piperonal and (4) coumarin alone. W. O. E.

Biological evaluation of drugs. E. KNAFFL. *Pharm. Monatshefte* **6**, 209-15 (1925).—An address. W. O. E.

Cultivation of drug plants. LUDWIG KROEBER. *Pharm. Ztg.* **70**, 1738-9 (1925).—The personal experience of the author is briefly described in cultural expts. with plants like marsh mallow, valerian, Chinese rhubarb, peppermint, digitalis, stramonium, thyme, mullein, fennel, mustard, etc. W. O. E.

Action of *Matricaria discoidea* and *M. chamomilla*. C. G. SANTESSON. *Pharm. Zentralhalle* **66**, 829-31 (1925).—Comparative expts. on the action of these 2 drugs develop no essential difference in their behavior. W. O. E.

Colloid salve therapy and colloid cosmetics. L. ZAKARIAS. *Pharm. Zentralhalle* **66**, 831-2 (1925).—Certain advantages are claimed and discussed for the new therapy,

notably in that they do not hinder the natural and pathological secretion of the skin and possess furthermore a considerably greater covering capacity than ordinary H_2O -sol. salves. W. O. E.

The extraction of oil of lemon. A. A. RAMSAY. *Agr. Gaz. N. S. Wales* **36**, 705 (1925).—A note on the methods. K. D. JACOB

Investigation on Indian opium. IV. Further experiments on the influence of fertilizers on the yield and morphine content of the latex from the opium poppy. H. E. ANNETT AND H. D. SINGH. *Mem. Dept. Agr. India*, Chem. Series **8**, 27-37(1925); cf. *C. A.* **15**, 248; **16**, 1484; **17**, 2767. —Org. fertilizers such as cakes and cattle manure in addition to giving an increased yield of opium appear to produce an increase in its morphine content. The increased morphine content does not seem to be brought about by the N or K_2O supplied by the fertilizer but rather by the P_2O_5 . **V. Experiments on oil content of the seed of the opium poppy.** H. E. ANNETT AND M. N. BOSE. *Ibid* 39-43.—The oil content of the seed of the opium poppy as grown in the United Provinces seems to be remarkably const. There are very small differences in the oil content of the seed of 9 pure races tested. There is no marked effect due to season, climate or fertilizers tested. The terminal and lateral capsules appear to produce seed of the same oil content. The process of lancing the capsules for opium has no effect on the oil content of the seed. **VI. Studies on the ash constituents of Indian opium.** H. E. ANNETT AND M. N. BOSE. *Ibid* 45-51.—There is a steady rise in the amt. of ash constituents of the latex of the opium poppy at each successive lancing up to the fourth, after which no increase appears. The compn. of the ash appears to be the same in each successive lancing and is not appreciably affected by fertilizing SO_3 and P_2O_5 detd. in the original opium increase rapidly in the first three lancements, the P_2O_5 increasing up to the fifth lancing. Cl is not present in the latex. The increase in ash constituents of each successive lancing is accompanied by a rapid falling off in total alkaloid content of the latex. This is accounted for by the rapid fall in morphine and to a lesser extent by the fall in narcotine content. Codeine and papaverine are present in more or less const. amts. in each successive lancing. It is possible that there is a physiol. connection between the rise in ash constituents and the fall in morphine. R. M. J.

Investigations of essential oils. ANON. *Bull. Imp. Inst.* **23**, 421-9(1925).—*Camphor leaves and twigs* from Uganda, contg. 11.8% H_2O , yielded on steam distn. 2.3% of oil or about 1.8% solid camphor. Two samples of *Massoi bark* (*Cinnamomum Massoia*, Schewe) from Papua yielded on steam distn. 6.0% and 6.3% of oil with: d_{15}^{15} 1.060, 1.064; $[\alpha]_D$ -0.90°, -0.34°; n_D^{20} 1.531, 1.536; phenols (as eugenol) 60, 79%, resp. The approx. compn. of the 2nd sample was: eugenol 79, safrole 14, other constituents (mostly terpenes) 7%. The oil is similar to that obtained by previous investigators from "massoy" bark from New Guinea. *Oil of Origanum Maru* from Cyprus had: d_{15}^{15} 0.904, n_D^{20} 1.4775, $[\alpha]_D^{20}$ +9°27', acid value 4.1, ester value before acetylation 4.1, ester value after acetylation 74.5, oil absorbed by a 5% NaOH soln. 2.5%, sol. in 1.4 vols. 80% alc. at 15°. The const. are similar to those of *marjoram oils* previously received at the Imp. Inst. from Cyprus and of com. Spanish *marjoram oils*. *Medang losoh oil* distd. in the Federated Malay States from the wood of *Cinnamomum parthenoxylon*, Meissn., had: d_{15}^{15} 1.103, $[\alpha]_D$ nil, ester value before acetylation 0.8, ester value after acetylation 3.5, congealing point +10°, sol. in 3.5 vols. of 90% alc. Distn. at 772 mm. gave: 234-7° 91, 237-9° 5, residue 4%, showing the oil consists principally of *safrole*. A. PAPINEAU-COUTURE

Saffron. GEORGES PIERLOT. *Chimie et industrie* **14**, 839-50(1925); cf. *C. A.* **30**, 263.—A monograph. *Oil of saffron* (obtained by steam distn. of the Et_2O ext.) had d_{15}^{15} 0.9514-0.9998, and a very slight *l*-rotatory power; it deposits rhombic crystals of a stearoptene m. 106° (recrystd. from a mixt. of Et_2O and petrole ether). Rectification of the oil *in vacuo* gives *sativol* (new), b_b 73°, b_s 69°, b_{760} 217° (corr.), d_{15}^{15} 0.9681, $[\alpha]_D$ 0, readily dehydrated to a mobile hydrocarbon, gives Denigès' reaction with $HgSO_4$, indicating that it is a tertiary alc. *Picrocrocine* recrystd. from $EtOAc$, m. 196°, showing that Kayser's product, m. 75° (*Ber.* **1884**, **1885**), must have been very impure. On hydrolysis it gives *sativol*, an uncrystallizable lactonic compd. which is apparently a phthalein, fructose and 1 mol. of HCO_2H . *Crocine* is best obtained by extn. with cold 70% $EtOH$ after extn. with Et_2O . It is next to impossible to obtain it entirely free from *picrocrocine*. *Croceline* is obtained by hydrolyzing *crocine* with dil. acids, filtering the red flocculent ppt., and recrystg. from Me_2CO or from $EtOAc$. Bibliography of 14 references. A. PAPINEAU-COUTURE

Essential oils in the Norwegian pharmacopea. GEORGES RENAUDET. *Parfumerie*

moderne 18, 297-9(1925).—The requirements of the Norwegian pharmacopea for essential oils and related products are given and briefly commented. A. P.-C.

The normal moisture content of essential oils. L. S. GLITCHITCH. *Parfums de France* No. 34, 351-2(Dec., 1925).—Detns. of H_2O (by distn. with dry xylene) on perfectly clear com. oils about a yr. old, and on the same oils after satn. with H_2O , gave: rosewood 2.4, 2.8; palmarosa 1.6, 2.4; Bourbon geranium 1.0, 1.6; Algerian geranium 1.0, 1.5; santal trace, 2.8; lavender (38% esters) 0.6, 1.0; spike-lavender 0.6, 1.0; bergamot (39% esters) trace, 0.3; French Mitcham mint 0.9, 1.0; citronella (Java) 1.1, 1.4; citronella (Ceylon) 0.4, 0.9; lemongrass 0.1, 2.8; French basil 0.6, 2.0; lemon 0.0, trace; juniper berries trace, trace; cedar trace, trace, resp. The max. H_2O which can be retained by these oils is of the order of 3% and is presumably merely in soln. in the alc. constituents of the oils. A. PAPINEAU-COUTURE

Oil of *Dacrydium elatum* from Tonquin. ÉTABLISSEMENTS A. CHIRIS. *Parfums de France* No. 34, 353(Dec., 1925).—A sample of oil distd. by the natives in the Langson region had: d_{15}^0 0.955, $[\alpha]_D^{20}$ -32°30', n unreadable, acid no. 1.54, ester no. 1.05, ester no. after cold formylation 56.7; ales. as $C_{10}H_{20}O$ free 22.70%, combined 0.41%, total 23.11%; insol. in 20 vols. of 85% and 90% alc., sol. in 0.1 vol. of 95% alc., with turbidity between 0.8 and 4.2 vols. Distn. *in vacuo* gave: 110-4° at 10 mm. pressure 70%; 115-20° at 2 mm. pressure 20%, resinous residue 10%. The first fraction after rectification had d_{15}^0 0.9391, $[\alpha]_D^{20}$ -55°50', n_D^{20} 1.50203, and consists of almost pure *l*-cedrene giving cedreneglycol, m. 167-8° (C. A. 19, 2726). The 2nd fraction crystallizes on cooling and consists of *d*-cedrol, m. 86-86.5°, $[\alpha]_D^{20}$ (in 19.15% xylene soln.) +8°50', giving phenylurethan, m. 106-7°. A. PAPINEAU-COUTURE

Some purity tests for ether. ALFRED WØHLK. *Arch. Pharm. Chem.* 82, 381-8 (1925).— H_2O_2 is detected by two reagents: (I) V_2O_5 0.4 g. in 4 cc. H_2SO_4 diluted to 100 cc. and (II) 1 g. TiO_2 in 10 cc. H_2SO_4 dil. to 100 cc. I gives a bright orange-red color with 0.1% H_2O_2 changing to a pale straw as the H_2O_2 is diluted to 0.0005%. II detects 0.0001% H_2O_2 as a very pale yellow, increasing in yellow with increase in concn. to a bright color for 0.01% and $K_2Cr_2O_7$ -red for 0.1% H_2O_2 . These two reagents also detect ethyl hydroperoxide but not diethyl peroxide. Nessler's reagent is used for CH_3CHO and C_2H_5CHO . Et_2O kept in partly filled containers and exposed to light gives peroxide tests, whereas Et_2O kept out of light and under N_2 remains unchanged. A. R. R.

Saponins and saponin drugs. KARL ALGOT KARSMARK. *Svensk Farm. Tids.* 29, 453-9, 467-72(1925).—A review of saponins giving a classified list of the drugs, suggestion as to chemical structures, method of preparations, tests and many references. A. R. ROSE

Additions to and modifications of the (French) Codex. ANON. *J. pharm. chim.* [8] 1, 578-89; 2, 31-45(1925).—The additions include stabilized alcohololates of horse chestnut and valerian; the modifications, neutralized olive oil, with full directions for neutralization with crystd. Na_2CO_3 ; cf. *Pharm. J.* 115, 327(1925). S. WALDBOTT

Neutralized olive oil. C. I. SAGE. *Pharm. J.* 115, 358(1925).—S. disapproves of the practice recently sanctioned by the French Codex (cf. preceding abstr.). Neutralized oils do not always retain neutrality and the small amts. of chemicals added will act as catalysts causing changes which lead to rancidity. S. WALDBOTT

Pharmacy in China. J. CAMERON AND K. K. CHEN. *Pharm. J.* 114, 433-6 (1925).—An historical comparison of the old and the new eras, with examples of the quaint modern prescriptions, each prefaced with the diagnosis of the case. The Chinese wts. and their metric equivs. are given, and wts. in actual use were found to be fairly accurate. S. WALDBOTT

The acidity of gelatins. J. RAE. *Pharm. J.* 115, 3-4(1925).—In 9 com. samples, the acidity varied from 0.3 to 3.85 cc. N NaOH in 10 g. dried gelatin; washing with H_2O removed less than 10% of the acid. The H_2O content varied from 7.5 to 16.0%. A definite limit of acidity should be adopted by the Brit. Pharm. (cf. C. A. 18, 2944). S. WALDBOTT

Analysis of Gregory's powder. J. F. LIVERSEEGE. *Pharm. J.* 115, 325(1925).—Of 27 samples of this powder (rhubarb 22 parts, ginger 12, light magnesia 66 parts (Brit. Pharm.)), 25 gave 11.4 to 14.1% of H_2O -sol. ext., 2 gave 10.4 and 10.7%. In 5 standard samples, H_2O -sol. ext. varied from 11.5 to 12.5%. However, 3 recent samples gave only, resp., 9.4, 7.3 and 11.8%. Considerable difference was found in the action of different samples of calcined MgO in preventing the soln. of the sol. matter in rhubarb. S. WALDBOTT

The active constituents of Cape aloes. H. KIEFFER. *Dissert. Basel*, 1925; *Pharm. J.* 115, 383-5(1925).—The purgative action of Cape aloes resides in 3 resins which are esters of *p*-coumaric acid and are obtained by the successive use of acetone, $AmOH$,

H₂O and AcOEt. The total constituents of Cape aloes are: (1) two possibly identical, very active, bright yellow resins, sol. in solns. of NaHCO₃, each about 30%; (2) a very active resin sol. in soln. of Na₂CO₃, 6–8%; (3) aloin, slightly active, 5%; (4) emodin, slightly active, 1.5–1.8%; (5) H₂O-sol. substances, inactive, 15–20%; (6) amorphous substances, insol. in acetone, producing abdominal pain but no purgation, 5–10%. The process of the Swiss Pharm. for the prepn. of ext. of Cape aloes is faulty, as it rejects as inert the bulk of the active constituents. S. V.

Contributions to the anatomy of monocotyledonous seeds. KARL SCHULTE. *Dissert.*, Basel, 1925; *Pharm. J.* 115, 411(1925).—The anatomy of the seeds of 18 plants of *Liliiflorae* and *Palmae* was studied at different stages of development as a basis for their identification in the powd. state. S. WALDBOTT

Contributions to the anatomy of the foliage leaves of official and pharmaceutically important Compositae. G. WEISS. *Dissert.* Basel, 1925; *Pharm. J.* 115, 411–2 (1925).—A list of the chief histological characters is given for 10 tribes of Compositae, and their relative value for identification is pointed out. The original contains a key for the recognition of about 53 Compositae, based on the characters of the leaves. S. WALDBOTT

Some notes on surgical dressings. F. A. HOCKING. *Pharm. J.* 115, 467–9(1925).—An address on the practical qualities of gauze, bandages, cotton, wool, etc. and the method of sterilization, with diagram of app. S. WALDBOTT

Decolorization of dilute solutions of syrupus glycerophosphatum compositus, B.P.C. G. J. W. FERREY. *Pharm. J.* 115, 493(1925).—A sample of undil. sirup. glycerophos. co., B.P.C., contg. 300 minims of tincture of cudbear per pint, lost its color in 4 days, on account of the reduction of cudbear by the invert sugar gradually formed (cf. Caines and Evers, *C. A.* 20, 94). The color is regained by admission of air. In dil. soln., however, decolorization is much retarded, because inversion of cane sugar does not seem to proceed to any appreciable extent in dil. solns. at room temp. (e. g., at 30°) even in presence of citric acid, etc., but does take place almost completely in the undil. sirup. The latter will diminish in color intensity during a given length of time more than the same sirup after (1:8) diln. S. WALDBOTT

Analytical control, its place in pharmacy. T. E. LESCHER. *Pharm. J.* 115, 518–20(1925).—An address on the responsibilities of the pharmacist and the manufacturer. S. WALDBOTT

The "hesperidin" of some plants. G. WANDER. *Dissert.* Bern, 1925; *Pharm. J.* 115, 520(1925).—To isolate "hesperidin," macerate the plant with cold 2% NaOH soln., strain and ppt. with HCl. Redissolve in dil. NaOH, ppt. with CO₂ gas, repeat the process 10 to 15 times, finally purify by extr. with EtOH or with NH₄OH. From *Hyssopus officinalis*, *Scrophularia nodosa*, *Barosma species*, *Mentha crispa*, *M. pulegium*, *Conium maculatum* (fruit and herb), *Hedeoma pulegioides*, *Toddalia aculeata*, *Linaria genistifolia* and *Capsella bursa-pastoris*, a substance different from hesperidin diosmin, C₂₈H₄₀O₁₁·2H₂O, the *rhamnoglucoside of diosmetin*, or 1,3,3'-trihydroxy-4'-methoxyflavone, was obtained. Hydrolysis with strong aq. alkali or with dil. H₂SO₄ under pressure yields rhamnose, dextrose and diosmetin. Diosmin is yellowish gray, m. 276–80°, loses H₂O at 120°, is insol. in NH₄OH, insol. or but little sol. in the usual solvents or in hot soln. (2 + 1) of CCl₄CH(OH)₁. No such rhamnoglucoside was obtainable from *Cuminum cyminum* (fruit), *Galium mollugo*, galls, *Mentha aquatica*, *M. piperita*, *Lythrum salicaria*, *Satureja hortensis* (minute traces only), *Viola tricolor*, *Tilia species*, *Verbascum species* (leaf), *Pilocarpus trachylophus*. *Verbascum* flowers gave a colorless, cryst. substance to be studied further. S. WALDBOTT

The U. S. Pharmacopeia, Tenth Decennial Revision. ANON. *Pharm. J.* 115, 545–6, 574–5, 634–5, 690–1, 720–1, 753(1925).—The general and specific deviations from the previous revision are pointed out. *Ibid* 116, 83(1926).—Corrigenda and addenda. S. WALDBOTT

Second International Conference for the unification of the formulas of potent drugs, Brussels, 1925. *Pharm. J.* 115, 547–50(1925).—The official final report and preliminary draft of international agreement are given. S. WALDBOTT

Some useful plants of India. D. PRAIN. *Pharm. J.* 115, 577(1925).—An abstr. of an address on Indian hemp and cinchona. S. WALDBOTT

The sumbul root of commerce. E. M. HOLMES. *Pharm. J.* 115, 633(1925).—A sample of sumbul root 50 years old, from *Ferula sumbul*, had still retained a distinct musky odor, which is absent in recent com. samples. The recent root, ascribed to *F. suaveolens*, Aitchison et Hemsl., has a faint taste of angelica and seems to resemble the old root in structure and size. Should both roots prove to be of identical structure through microscopic examn., it would then be probable that the typical *Ferula sumbu*,

plant does not possess the musky odor, and that the musky-smelling root of 50 years ago belonged to a variety that has since died out, having possibly grown in a limited locality (cf. *C. A.* 18, 2787).

S. WALDBOTT

A simple method of testing spiritus aetheris nitrosi. J. RAE. *Pharm. J.* 115, 633-4 (1925).—Into a 50 cc. Nessler tube put 20 minims of soln. *A* ($\text{NH}_2\text{C}_6\text{H}_4\text{SO}_3\text{H}$ 0.5 g.; HCl , Brit. Pharm., 7.5 g.; H_2O to make 100 cc.) and 20 minims of a 1 in 10 aq. soln. of the spirit. After 5 min. add 30 minims of soln. *B* (strong NH_4OH 10 cc., H_2O to make 100 cc.) and H_2O to make 50 cc. Compare the pale yellow to reddish brown color (permanent for hrs.) with that of a standardized $\text{K}_2\text{Cr}_2\text{O}_7$ soln. also dild. to 50 cc. Spirits contg., resp., 2.20, 1.52, 1.30% of NO_2Et , detd. by means of the nitrometer, are equiv. to, 42, 25 and 20 minims, resp., of a 1% $\text{K}_2\text{Cr}_2\text{O}_7$ soln. Whether a spirit is within the 1.25% limit of the Brit. Pharm. is easily detd. by this method.

S. W.

Some observations on light bismuth carbonate of commerce. B. F. HOWARD AND O. CHICK. *Pharm. J.* 115, 661-2; A. J. JONES. *Ibid* 711 (1925).—Of 10 com. samples, only 3 had the Bi_2O_3 content demanded by the Brit. Pharm. and a low content in CaCO_3 (0.1-0.25%). In the other 7, CaCO_3 was excessive (2.1-4%), likewise chlorides BiONO_3 was in excess in 8 cases. The "lightness" was measured as the "bottle-filling capacity" of 1 lb. The best grade occupied 45 fluid ounces, heavier grades less, to the limit of 30. A density of 120 ounces was obtained by pptn. with CaCO_3 at 40° , but the powder contained 9% CaCO_3 and only 84.6% Bi_2O_3 . No definite relation exists between density and bulk of emulsion in H_2O . The A. J. Jones method of prepn (*C. A.* 20, 95) is recommended. J. suggests that the possible use of the hard tap water of the London area (250 p. p. m.) may have caused the high % of CaCO_3 . In 1 sample he had found heavy traces of phosphates.

S. WALDBOTT

The essential oils and related substances of the new U. S. Pharmacopeia. H. FINNEMORE. *Pharm. J.* 116, 29-32 (1926).—A crit. review of the alterations from the previous revision in the monographs on essential oils and similar materials.

S. W.

Capacity and graduations of dispensing bottles (STANNARD) 1.

Pharmaceutical preparation for use as an anodyne. I. FLODQUIST and I. G. BLOMQUIST. U. S. 1,569,956, Jan. 19. A mixt. adapted for treating otitis, etc., comprises dextrose 50, levulose 10, adrenaline 0.02, cocaine 10, isoamylhydrocuprein 0.75, phenol 1 and H_2O 28.23 parts.

Synthetic drug. WELLCOME FOUNDATION, LTD. AND W. H. GRAY. Brit. 234,677, Aug. 12, 1924. A glucoside of Na *p*-aminophenylstibinate is prepd. by interaction of glucose and Na *p*-aminophenylstibinate in aq. soln. in the presence of an excess of alkali for a prolonged time. The product may be used for treating "tropical diseases."

Acyl derivatives of cyclic amino mercapto metal compounds. CHEMISCHE FABRIK AUF AKTIEN FORM. E. SCHERING. Brit. 234,806, June 2, 1924. A cyclic amino mercapto metal compd. is acylated or a cyclic amino mercapto compd. is first acylated and a metal then introduced into the mercapto group. The products are stable in aq. soln. and possess therapeutic properties. Among the compds. referred to are: the Na salt of 4-acetyl-amino-2-argentic mercapto benzoic acid and the corresponding auro compd. and the diphenylurea compds. derived from these by treatment with phosgene; 4-*m*-aminobenzoylamino-2-auro mercapto benzoic acid, which with phosgene yields a urea deriv.; other examples also are given.

Synthetic therapeutic gold compounds. FARBERWERKE FORM. MEISTER, LUCIUS and BRÜNING. Brit. 234,772, June 2, 1924. (Addn to Brit. 225,875; *C. A.* 19, 1615). Complex Au compds. are prepd. by the interaction of Au salts with heterocyclic or acyclic compds. derived from thiourea, other than a thio benzimidazole; the products, if acidic, may be converted into salts. Na salts may be formed from the products obtained from thiohydantoic acid and thioarbuturic acid by reactions with K auribromide.

Medicinal mixture. J. R. PROCHNOW. U. S. 1,569,202, Jan. 12. A compn. for the treatment of bacterial affections of the genito-urinary tract comprises constituents of balsam copaiba, sweet spirits of niter and $(\text{CH}_2)_6\text{N}_4$ with formaldehyde which is produced in the soln.

Ampules of reacting or unstable substances. M. HAHN. U. S. 1,570,346, Jan. 19. Substances such as dry sera and their solvents are kept sep. in glass ampules which are connected with each other by a capillary tube sealed with a mixt. of paraffin and wax or other material m. 45-100° so that the seal may be melted out and the substances mixed immediately before use.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

Salt and allied chemicals. GEO. E. GOLLOP. *Can. Chem. Met.* **9**, 259-64(1925).—The nature and extent of the salt deposits underlying Michigan and S. W. Ontario are set forth, a detailed account is given of the manuf. of special brands of very pure salt, of NaOH, liquid Cl, pure HCl and bleaching powder as carried out at the plant of the Canadian Salt Co., Windsor, Ont., and many interesting features of the plant itself are described.

E. G. R. ARDAGH

Salt, bromine and calcium chloride in 1924. K. W. COTTRELL. *U. S. Geol. Survey, Mineral Resources of U. S., 1924*, Pt. II, 141-9 (preprint No. 12, publ. Dec. 15, 1925). Cf. *C. A.* **19**, 876.

E. J. C.

The manufacture of sodium thiosulfate. ROBERT HAZARD. *Rev. chim. ind.* **34**, 334-8, 365-70(1925).—A review.

A. PAPINEAU-COUTURE

The catalytic preparation of sulfur trioxide. ANON. *Chem. Age* (London) **13**, 320-1(1925).—The following factors in the conversion of SO_2 to SO_3 , as carried out in the Mannheim contact process for the mfg. of H_2SO_4 , may affect the conversions: the % SO_2 in the entering gas; the presence or absence of H_2O in the gas; the chem. compn. of the catalyst; the reaction temp.; the state of subdivision of the catalyst; the space velocity. It being impossible on a lab. scale to duplicate plant conditions as regards size of ferric oxide lumps and gas velocities, finely powd. oxide was used with a gas velocity higher than that used in the plant. H_2O in the gas mixt. is not harmful in moderate amts, indeed, it appears to have a beneficial influence, which is probably due to its hydrolytic action on $\text{Fe}_2(\text{SO}_4)_3$. From analyses of the catalyst before and after the expts. it is concluded that pyrites cinders undergo a no. of changes in the oxide shaft, the sulfides are roasted to SO_2 and a certain considerable amt. of sulfate is formed. The distribution of As in the shaft was also detd. and proves that the oxide acts as a trap for the As. The arsenical compd. formed when As is absorbed was isolated and has the compn. $2\text{Fe}_2\text{O}_3 \cdot \text{As}_2\text{O}_3$. Expts. undertaken to show the effect of As on the conversions showed that the catalytic value of the oxide is lowered and that a higher temp. is needed for the conversion.

J. H. PERRY

How sulfur is mined with superheated water. W. T. LUNDY. *Chem. Met. Eng.* **32**, 917-9(1925).—About the Frasch process as used at Freeport, Texas.

E. J. C.

The manufacture and uses of phosgene. G. M. DYSON. *Industrial Chemist* **1**, 557-41(1925).

E. J. C.

Progress of the nitrogen industry in 1925. EDW. B. MAXTED. *Chem. Age* (London) **13**, 644-6(1925).

E. J. C.

Various methods of manufacturing hydrogen. P. E. RAASCHOU. *Proc. Fourth Intern. Congress of Refrigeration* **2**, 1199-211(1924).—Comparison of the Fe-steam method and of the continuous method (water-gas or a mixt. of water-gas and power gas is freed from most of the CO according to $\text{CO} + \text{H}_2\text{O} \rightleftharpoons \text{CO}_2 + \text{H}_2$, and the CO_2 and residual CO are eliminated) for the production of a 3:1 H-N mixt.

A. P.-C.

The hydration of lime. W. G. WHITMAN AND G. H. B. DAVIS. *Ind. Eng. Chem.* **18**, 115-20(1926).—This paper deals with the effect of 3 variables—ratio of water to lime, temp. of hydration, and agitation—upon the properties of hydrated lime. The quality of the hydrated material was evaluated by 3 different methods: by rate of reaction of the lime suspension with acid; by rate of settling in water; and by microscopic examn. The best product is prepd. by hydrating at moderately high temps. with excess water.

L. B. M.

Aktivin and perborate. B. WAESER. *Chem.-Ztg.* **49**, 853-5(1925).—For *laundrying* Aktivin (Na deriv. of chloro-*p*-toluenesulfonamide) belongs to the class of mild bleaching agents; org. colors suffer more by Aktivin than by perborate and it also acts more quickly upon the fiber itself. Aktivin is not sufficient for a complete bleach; certain colors are proof against perborate. Addition of 1% Aktivin or perborate to a starch suspension with steam-stirring for 10 min. results in a *sol starch* of a compn. that stands between starch and dextrin, and when evapd. yields a white product with perborate from corn and wheat starch and a yellowish product with Aktivin. Perborate leaves borax as a by-product which is not objectionable while Aktivin yields *p*-toluenesulfonamide. Aktivin shows no advantage over perborate. The *disinfecting properties* of Aktivin are notable, and as a plant insecticide it deserves further study. Since the ion concn. is the true measure for all bleaching agents, it is probable that each agent possesses its own optimum of temp. and concn. at which max. effects can be produced. A bibliography of 15 titles is given in footnotes.

P. ESCHER

German fuller's earth—deposits, preparation and marketing. R. DECKERT. *Eng. Mining J.-Press* 120, 848(1925).—Deposits of fuller's earth are found in Lower Bavaria. The phys. condition of this earth is extremely altered during treatment with HCl. The raw earth has a smaller bleaching power than the American earth, but after the HCl treatment it is greater than the latter. The earth is sold either as a mixt. of raw and treated earth, or raw high-active earth, or as earth contg. a small amount of discoloring matter (C). Owing to inflation, much old-fashioned machinery is still used in the industry.

Pearl essence: its history, chemistry and technology. H. F. TAYLOR. *Bur. Fisheries, Document No. 989*, 16–36(1925).—The silvery substance deposited in the skin of many species of fish is rubbed from the scales, freed from foreign matter, and suspended in water or other suitable liquid. This constitutes pearl essence. A complete bibliography is appended.

W. H. BOYNTON

W. H. BOYNTON

Polishing wheel leather (BOWKER) 29. Production of H_2SO_4 by electrolysis (SAXON) 4. H_2SO_4 from a quadruple mixture (SAXON) 4. A mass-action equation for compressed gases with application to the Haber equilibrium data (GILLESPIE) 2.

EITEL, WILHELM: **Ueber die Synthese der Feldspatvertreter.** Leipzig: Akadem. Verlagsges. 258 pp. R. M. 25.

MOLITOR, H.: **Fabrikation der Soda.** Leipzig: Max Jänecke Verlagsbuchhandlung. 231 pp. Price, paper, M. 11.60; bound, M. 13.10.

ZERT, K., AND NOSEK, FR.: **Ueber Entfärbungskohle im allgemeinen und über "Carboraffin" und "Norit" in besonderen.** Tagesfragen aus der Zuckerindustrie, No. 2. Edited by Oskar Wohryzek. Magdeburg, Germany: Albert Rathke. G. M. 3 (unbound). Reviewed in *Intern. Sugar J.* 27, 666(1925).

Hydrofluoric acid. M. BUCHNER. *Brit.* 234,852, June 2, 1924. Pure HF is obtained from impure fluorspar or similar substances contg. SiO_2 as well as F by converting the mixt. of HF and H_2SiF_6 (obtained by decomposing the crude material with H_2SO_4) wholly into H_2SiF_6 by the action of SiF_4 and then treating the H_2SiF_6 with fluoride of Na, K, Ba or like fluoride to produce pure HF and a fluosilicate which on heating yields a fluoride and SiF_4 for further use.

Phosphoric acid. E. MERCK. *Brit.* 234,122, May 14, 1924. H_3PO_4 is treated with PH_3 in order to sep. As present as an impurity. Excess of PH_3 may be removed by passing CO_2 through the H_3PO_4 and the As which forms flakes may be removed by filtration of the dild. acid.

Apparatus for producing and recovering hydrocyanic acid, etc. M. J. BROWN. U. S. 1,569,171, Jan. 12. Solns. such as those of acid and cyanide are continuously supplied to a reaction vessel and gas produced and spent soln. are continuously and separately withdrawn.

Ammonia synthesis. H. HARTER. U. S. 1,570,485, Jan. 19. One part of a mixt. of H and N is treated with a catalyst at a pressure exceeding 400 atm. and another part of the mixt. is treated at a lower pressure, e. g., about 300 atm. The treated gas of higher pressure is expanded to lower pressure, the gases are united and NH_3 is condensed from them. The use of the different pressures serves to permit efficient temp. control and heat interchange. Cf. C. A. 20, 96.

Ammonia synthesis. I. W. CEDERBERG. U. S. 1,570,333, Jan. 19. In producing catalyzers for NH_3 synthesis, anhyd. FeCl_3 , or other compds. of metals of the Fe group are mixed with cyanides, e. g., KCN, in liquid anhyd. NH_3 , the mixt. is freed from surplus NH_3 and is heated in a nonoxidizing atm. without fritting.

Ammonia soda process. H. A. GALT. U. S. 1,570,299, Jan. 19. Crude ammonia, concd. brine and a low test CO_2 are brought into contact with each other to carbonate the ammonia without material pptn. of NaHCO_3 . High test CO_2 is passed into the soln. and NaHCO_3 thus pptd. and the latter is calcined to form Na_2CO_3 and produce the high test CO_2 , thus in effect concg. the low test CO_2 .

Separating potassium and sodium hydroxides. SOC. ANON. POUR L'IND. CHIM. À BÂLE. *Brit.* 234,072, May 15, 1924. NaOH and KOH present together in concd. aq. soln. are sep'd. by a process of fractional crystn. in which the KOH is sep'd. at a relatively high temp. and the NaOH by dilg. the remaining mother liquor and cooling. Inorg. salts when present in the original liquor are advantageously removed by concg.

and filtering and org. impurities are removed by evapg. and heating. Several detailed examples are given, with concns. and temps. used

Sodium thiosulfate. H. HOWARD. U. S. 1,570,253, Jan. 19. In producing $\text{Na}_2\text{S}_2\text{O}_3$ by the interaction of Na_2SO_3 with S, the S for the reaction is supplied in gaseous form.

Sodium thiocyanate. M. DARRIN. U. S. 1,570,047, Jan. 19. An aq. soln. contg. NaCNS , $\text{Na}_2\text{S}_2\text{O}_3$ and finely divided impurities (such as is obtained by treatment of gas-purifying materials) is concd. until it b₇₆₀ 130–135°, cooled to between the transition points of $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ and NaCNS hydrate, seeded with crystals of a hydrate of $\text{Na}_2\text{S}_2\text{O}_3$ to cause a gelatinous ppt. of $\text{Na}_2\text{S}_2\text{O}_3$ capable of entrapping the finely divided impurities. The ppt. is sepd. and the filtered soln. is concd. until its b. p. is approx. that of a satd. soln. of NaCNS and is then cooled to cause crystn. of anhyd. NaCNS .

Potassium carbonate. H. KLOPSTOCK and W. NEUMANN. Brit. 234,585, April 1, 1924. See U. S. 1,562,891 (C. A. 20, 482).

Aluminium fluoride, etc. RUGERSWERKE-AKT.-GES. Brit. 234,485, May 26, 1924. Clay, bauxite or similar materials contg. Al_2O_3 and SiO_2 are treated with aq. HF (the aluminous material being in excess) so that the Al fluosilicate which is first formed is decomposed, with formation of AlF_3 and SiO_2 . Any SiO_2 remaining in soln. may be pptd. by Al_2O_3 or reactive clays and the pptd. SiO_2 may be used for "binding bacteria," for decolorizing liquids, etc.

Crystallizing acid sodium pyrophosphate, etc. J. T. MILLAR. Brit. 234,197, Feb. 29, 1924. Crystd. salts are prepd. by spraying a heated soln. (e. g., a soln. of acid Na orthophosphate at a temp. of 110° and a d. of 1.65–1.75) into a chamber (which may be heated to 160–200°) in which a quantity of crystals of the desired type has been previously placed. An agitating device in the chamber turns over the crystals as they form "in the manner of a ploughshare."

Hypophosphites, etc. E. MERCK. Brit. 234,138, May 17, 1924. H_3PO_4 and phosphites are obtained together with hypophosphites by treating an aq. suspension of $\text{Ca}(\text{OH})_2$ or other alk. earth hydroxide with P (which may be in the form of sticks) and burning the PH_3 which is evolved. The temp. is raised to start the reaction and when the pressure has risen to 6 atm. the PH_3 is allowed to pass out of the autoclave, through lime towers, to ovens in which it is burned to H_3PO_4 . A stream of N is used for expelling PH_3 from the liquor remaining in the autoclave and it is filtered. The ppt. of lime and Ca phosphite is washed, dissolved in HCl and repptd. by NaOH free from carbonate. The filtrate is neutralized with CO_2 , heated and filtered, and evapd. *in vacuo* to obtain hypophosphite.

Large crystals of metals, oxides or salts. GENERAL ELECTRIC CO., LTD. Brit. 234,449, May 26, 1924. Material to be formed into large crystals is packed in a container which is tapered to a point at one end and is heated progressively from the tapered end to a temp. above the m. p. of the material under treatment.

Alumina. T. R. HAGLUND. Brit. 234,830, June 2, 1924. In fusion of bauxite or similar raw materials in an elec. furnace with reducing agents and sulfide to obtain alumina in a sulfide melt, the raw material is subjected to a preliminary treatment to convert the Fe present into FeS . Numerous details are given.

Alumina. R. JACOBSSON. U. S. 1,570,353, Jan. 19. See Brit. 221,209 (C. A. 19, 877).

Alumina. HOEGANAËS-BILLESOLMS AKTIEBOLAG. Swed. 59,865, Nov. 17, 1925. Materials contg. Al_2O_3 are decomposed by HCl , crystals of AlCl_3 are pptd. by supersatg. the soln. with HCl , the crystals are calcined and the HCl expelled is returned to the process. All or part of the mother liquor from the pptn. app. is introduced into the decompn. app. in such quantities that equal amts. of Al_2O_3 are constantly introduced in the pptn. app. in the form of soln. and removed from it in the form of crystals. And likewise the amt. of HCl and H_2O vapor introduced into the pptn. app. should be equal to the amt. which can be gained by calcination of the crystals removed from the app. during the same period.

Titanium oxide. DEUTSCHE GASGLÜCHT-AUER-GES. Brit. 234,518, May 24, 1924. Acid solns. of Ti sulfate are hydrolyzed under pressure at 160–180°. A soln. of 1.35–1.55 sp. gr. and total free and combined acid of 25–45% is used and a salt such as Na_2SO_4 (or Fe sulfate if the product need not be free from Fe) may be added to weaker solns. to give the specified sp. gr.

Nitrogen. HYDRAZOTE. Brit. 234,104, May 19, 1924. N is obtained from air or other gases rich in N and also contg. some O (such as residual gases obtained in the manuf. of O by liquefying air, or combustion gases) by circulating the gases over hot

reduced Fe, the Fe oxide being then reduced to render the process cyclic. An app. is described.

Hydrogen from gaseous mixtures. SOC. L'AIR LIQUIDE (SOC. ANON. POUR L'ETUDE ET L'EXPLOITATION DES PROCÉDÉS) G. CLAUDE. Brit. 234,041, May 15, 1924. In the manuf. of H by partial liquefaction of gaseous mixts. contg. it, *e. g.*, coke-oven gas or illuminating gas, the final washing of the compressed H, to remove CO, before expansion, is effected by liquefied N intended for the lubrication of the H-expansion engine.

Activated and decolorizing carbons. G. W. WALLACE. Brit. 234,161, Jan. 25, 1924. See U. S. 1,565,129 (C. A. 20, 483).

Activated carbon from bone char. R. DUNCALFE, R. B. DREW and J. O. CUTTER. Brit. 233,840, March 29, 1924. Bone char or bone char dust is leached with a dil. H_3PO_4 soln. to obtain activated C and H_3PO_4 . The bone char may receive a preliminary re-calcination and may be washed with H_2O after leaching and dried. The combined washing H_2O and leaching soln. is treated with H_2SO_4 in considerably less than the quantity equiv. to the Ca and Mg present. On evapn. di-Ca II phosphate is pptd.

Storage of acetylene and other gases. SVENSKA AKTIEBOLAGET GAS-ACCUMULATOR. Brit. 234,777, May 27, 1924. Containers for storage of C_2H_2 or other gases are filled with balls or lumps which may be formed from kieselguhr, brick dust, pumice, asbestos, cellulose, silk or other fibrous materials agglomerated by cement, $ZnCl_2$ or other suitable binder. The interstices between the balls or lumps are filled with loose kieselguhr or similar material, and the balls may be made with a core of solid material such as charcoal.

Storing acetylene or the like in silica gel. GAS ACCUMULATOR CO. (UNITED KINGDOM), LTD. Brit. 234,462, May 22, 1924. A porous mass of silica gel, alone or with cement or other substances, is used as a filling for cylinders for holding C_2H_2 or other explosive gases. If used in lumps, the interstices may be filled with kieselguhr.

Silica gel. C. S. TERRESWORTH. U. S. 1,570,537, Jan. 19. Silicic acid is allowed to set to a gel in contact with an added porous substance such as diatomaceous earth which serves to produce a highly adsorptive material.

Purifying bauxite. T. R. HAGLUND. U. S. 1,569,483, Jan. 12. In treating bauxite, oxides of Fe, Si and Ti are removed and the Al_2O_3 is dissolved in a sulfide-contg. slag by fusing the bauxite with Fe sulfide or a similar sulfide-yielding material and a reducing agent such as C and sepg. the sulfide- Al_2O_3 slag from the reduced alloy.

Treating kieselguhr for filtration and similar purposes. CELITE CO. Brit. 234,735, Dec. 28, 1923. The process of Brit. 229,021 (C. A. 19, 3004) is modified in that the finely divided diatomaceous earth is calcined without addn. of other material.

Separating solids from solutions in coarse crystals. AKTIESELSKAPET KRISTAL. Norw. 42,020, Oct. 19, 1925. A supersatd. soln. is passed through an agglomeration of crystals of the substance to be sepd., the soln. in the crystn. vessel being kept at a nearly const. temp.

"Artificial snow" for stage effects. J. A. RICE. U. S. 1,569,396, Jan. 12. Powd. casein or a similar protein material soaked in H_2O in the presence of rennet is mixed with a foaming agent such as NH_4 resinate, the mixt. is agitated to produce a froth and a sol. Ca salt, *e. g.*, $CaCl_2$, is added.

Mat finish on coated articles. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 234,813, May 28, 1924. Material contg. bituminous or tarry substances, *e. g.*, asbestos board with a cement or magnesia binder impregnated with asphaltic material derived from still wax or petroleum tailings, is superficially treated with concd. H_2SO_4 or other strong inorg. acid, to give the surface a mat finish.

Composite metal articles. C. P. BYRNES. U. S. 1,562,145, Nov. 17. Composite metal products adapted for stair treads, ornamental articles, etc., are prepd. by mixing loose granules of one metal, *e. g.*, steel, with another metal of lower m. p., *e. g.*, Al, Cu or Al bronze, in molten condition, and permitting solidification of the molten metal.

Articles from cellulose nitrate and similar compositions. E. L. SCHUMACHER. U. S. 1,559,791, Nov. 3. Spectacle frames or other articles are blanked out from unseasoned stock formed from pyroxylin or similar compns. and the cuttings from the unseasoned stock are returned to the "base stock" for reuse in the process to avoid wastage. The blanked out frames, etc., are then seasoned.

Printing surfaces. ACTUALITE ILLUSTREE SOC. ANON. Brit. 234,140, May 19, 1924. A cellulose acetate compn. or similar material is used for forming matrices for making stereotype plates, which are made of material which softens at a lower temp. than the matrix.

Uniting sheets of cotton fabric or other materials under heat and pressure with

phenolic condensation products. J. McINTOSH and J. M. TAYLOR U. S. 1,557,302, Oct. 13.

Cements. ECONOMY FUSE & MFG. CO. Brit. 233,907, June 16, 1924. Cements for dental or other purposes are formed with a content of an aluminate, e. g., 2–10% of Ca aluminate, and used with a setting liquid comprising H_2PO_4 . Various fillers and auxiliary ingredients may also be added in accord with the use to which the cement is to be put and the rapidity of setting, etc., desired. Numerous examples are given.

Putty and filler cement. M. W. NELSON and W. F. NELSON. U. S. 1,570,169, Jan. 19. A putty for glass and wood of window sash, etc., is formed of plaster of Paris 14 lbs., PbO 3–5 oz. and varnish 2 quarts.

"Glass-cloth." A. S. TURNER. U. S. 1,557,185, Oct. 13. Bleached muslin is sized with a Na silicate compn., dried and coated with paraffin and carnauba wax.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

A machine for transverse tests of clay and glass laboratory specimens. A. C. HARRISON *J. Am. Ceram. Soc.* 8, 774–83(1925). C. H. KERR

The ceramics of Argentina in industry and art. A. S. DÍAZ. *Rev. facultad ciencias* 3, No. 2, 33–46(1925).—There are large deposits of Fe-free kaolin in Siján, Catamarca and Cerro de Velasco near La Rioja. In Mar del Plata and Balcarce (Buenos Ayres) are deposits of clay suitable for the manuf. of refractory materials. Argentina has no porcelain industry. Pottery is made from impure materials and has a good domestic market. The great demand for roof tiles, sewer pipes and sinks is covered by the U. S. and Europe in spite of the country's wealth of raw materials. Refractory plates are manufd. throughout the whole country by the most varied processes, from very primitive to entirely modern ones, but generally in a rather empirical manner entailing considerable waste. They gradually replace the imported product in all domestic industries.

MARY JACOBSEN

X-ray investigation of clays and some other ceramic substances. A. HADDING. *Trans. Ceram. Soc. (England)* 24, 27–32(1925).—X-ray "atom" analysis corresponds to ultimate chem. analysis, while X-ray "molecule" analysis shows the structure of the material. In the finest residues of clay obtained by elutriation only cryst. material is found. The only minerals found in quantity in normal clays are quartz, kaolinite and muscovite. A brief description of the X-ray app. used and some diagrams obtained are given.

H. F. K.

Introductory study of the Puget Sound shale and glacial clays. T. O. SMITH. *J. Am. Ceram. Soc.* 8, 849–52(1925). C. H. KERR

Some properties of clay-sillimanite mixtures. H. S. HOULDSWORTH. *Trans. Ceram. Soc. (England)* 24, 33–41(1925).—To Farnley fireclay, increments of natural corn. sillimanite were added and the effects on the phys. properties noted. With increasing sillimanite content the drying and burning contraction decreased, porosity at high temps. increased and a more regular coeff. of thermal expansion resulted. The refractoriness and the resistance to attack of slag and soda lime glasses were decidedly greater with sillimanite contents over 50%.

H. F. K.

Some observations on the drying properties of clays. D. C. LINDSAY and W. H. WADLEIGH. *J. Am. Ceram. Soc.* 8, 677–93(1925).—A preliminary report. Evapn. is directly proportional to surface area exposed per unit. wt. of dry clay. Rate of drying is very important and best rate varies with type of clay. Causes of drying injuries are discussed. A lab. drying cabinet is described.

C. H. KERR

Kaolin (1) Thermal changes. (2) Rational analysis of clay. K. A. VESTERBERG, et al. *Arkiv. Kemi Min. Geol.* 9, No. 14, 1–26(1925).—Kaolin on being heated to 800° does not decompose into free Al_2O_3 and SiO_2 , but forms $Al_2Si_2O_7$, which is sol. in HCl. On heating kaolin to 1000° the product is completely insol. in HCl. Glagerite ($Al_2O_3 \cdot 2SiO_2 \cdot 2.55H_2O$) differs from kaolin in that it is 50% sol. in 20% HCl, and is rendered completely sol. by heating to 750°. Pyrophyllite differs from both the other minerals in that it is not rendered sol. by heating. (2) The rational method recommended is: 1 g. clay is heated for 1 hr. with 10 cc. 20% HCl, and the undissolved portion is again subjected to the same treatment, part of it directly, and the remainder after being heated to 800°. Sol. Al_2O_3 is detd. in the HCl soln., and the sol. SiO_2 in the residue is extd. by boiling with 50 cc. of 5% Na_2CO_3 , 0.5% NaOH, and 25 cc. 5%

KOH. The differences between the Al_2O_3 and SiO_2 values obtained before and after heating give the Al_2O_3 and SiO_2 present as kaolin (they should be molecularly 1:2) and the kaolin is calcd. by multiplying Al_2O_3 by 2.533. Analyses of clays from Sweden and Germany gave kaolin contents varying from 73.9 to 1.65% B. C. A.

United States Government master specification for fireclay. Federal Specification Board, *Spec. No. 334*; Bur. of Standards, *Circ. No. 298*, 6 pp. (1925). E. J. C.

The influence of exposure on the chemical and physical properties of certain fireclays. W. HUGILL AND W. J. REES. *Trans. Ceram. Soc. (England)* **24**, 42-62 (1925).---Two sandy micaceous clays and one compact fine-grained clay were exposed to weathering for 12 months. The chem. analysis before and after exposure showed a loss of SiO_2 of about 1%, not much change in Fe_2O_3 and TiO_2 , definite but varied losses among the samples of the alkalis and alkaline earths, and gains in Al_2O_3 and loss on ignition. The greatest gain was in the Al_2O_3 content, this amounting to 2.79% in one case while the same clay gained 0.85% in loss on ignition. The refractoriness of each weathered clay increased about one cone, while the drying shrinkage decreased 8-25%. At 1600° more melt formed from the clay which had not been exposed. The working properties of the more siliceous clays were improved with exposure while the more aluminous clay suffered thereby. H. F. K.

The action of heat on kaolinite and on kaolinitic clays. V. VERNADSKII. *Trans. Ceram. Soc. (England)* **24**, 13-21 (1925).---The formula $\text{Al}_2\text{Si}_2\text{O}_5(\text{HO})_2 \cdot \text{H}_2\text{O}$ is suggested for kaolinite to distinguish the 2 kinds of H_2O which V. asserts are present. The chem. H_2O is driven off by heating to 450-460°, while the zeolitic H_2O is expelled gradually below and above this temp. The residue is held to be leverrierite, $\text{Al}_2\text{Si}_2\text{O}_7$, and not a mixt. of free Al_2O_3 and SiO_2 . The formation of sillimanite and mullite from leverrierite is discussed with the aid of certain cyclic structural formulas. H. F. K.

Alumina-silica minerals in firebrick. W. J. REES. *Trans. Ceram. Soc. (England)* **24**, 23-6 (1925).---The H_2F_2 -insol. residues in firebricks increase definitely with the temp. of firing and with the Al_2O_3 content. The residues agree closely with the compn. of mullite ($3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$). H. F. K.

The manufacture and physical properties of dry-press brick. J. H. KRUSON AND C. A. SMITH. *J. Am. Ceram. Soc.* **8**, 829-32 (1925).---Advantages over stiff-mud brick are given. C. H. KERR

Firebricks for furnaces using pulverized fuel. ANON. *Brit. Clayworker* **34**, 255 (1925).---Speaking generally, bricks which will best resist the action in a furnace using pulverized fuel are those with a close surface and so accurate a shape that they can be laid with the thinnest possible joints. Beyond this, silica bricks—if they do not spall—are usually more durable than fireclay bricks, but no general statement such as this should be understood as excluding all fireclay brick. A method of comparing the resistances of different bricks to pulverized fuel, as devised by Steinhoff of Dortmund, is described. H. G. SCHURECHT

Shales of North Carolina. J. L. STUCKEY. *J. Am. Ceram. Soc.* **8**, 843-8 (1925).---They are well adapted to the manuf. of face brick, hollow blocks, sewer pipe, etc. C. H. KERR

Progress report on research of paving brick from Iowa shales. D. A. MOULTON. *J. Am. Ceram. Soc.* **8**, 694-701 (1925).---Eleven shales were tested, in full-size bricks. Five were found excellent. The soft-mud, roller expression machine gave equal or better results than the stiff-mud process. MgO reduced the rattler test from 27 to 22% loss, and changed color to buff. C. H. KERR

The manufacture of graphite pencils and its relationship to ceramics. H. V. PERRIER. *Chimie et industrie Special No.*, 339-45 (Sept., 1925).---Descriptive, showing the analogy with and difference from ceramics due to the use of clay. A. P.-C.

Calcining as an aid to grinding. W. M. MYERS. *J. Am. Ceram. Soc.* **8**, 839-42 (1925).---Expts. show no value commensurate with the cost. C. H. KERR

Bureau of Standards investigation of feldspar. R. F. GELLER. *Ceramist* **6**, 708-16 (1925).---G. reports the progress of the investigation of the factors affecting glaze hardness. Glazes to be tested are abraded by a falling stream of sand and the amt. of surface worn away by a definite weight of sand is detd. by an Ingersoll Glarimeter. Preliminary data are given in the form of a graph. The feldspar investigation is divided into 2 parts. The first part consists of a comparison of tests for softening point, fusion point, chem. analysis, fineness as carried out by cooperating industrial labs. and the Bureau. The second part includes studies of viscosity of feldspars at softening temps. and the effect of feldspars on the burning range, porosity, color and strength of vitreous and semi-vitreous bodies. Petrographic examns. are being made

in all cases. G. reports the outcome of studies on fineness, chem. analyses and quartz content to date.

Black cores. ANON. *Brit. Clayworker* 34, 256(1925).—Flaws in ceramic ware are often caused by the intrusion of particles of foreign matter into the bodies during manuf. As a rule, Fe_2O_3 , CuO or particles from the furnace are the sources. "Black core" is mainly attributed to the decompn. of pyrites. These cores have the form of small cone-shaped hollows contg. a fraction of the pyrites in the bottom. To prevent these flaws, ventilation should be good, and heating should be carried out slowly during the oxidation period, particularly as the temp. approaches 1000° . If the whole of the C present has not been oxidized when the temp. has reached 1000° , pyrites, which, under ordinary conditions decomposes rapidly at 850° , will most likely act with the clay, forming black core. The formation of this defect is less frequent in dry-pressed bricks than in the plastic-made of fine texture. The presence of large grains of calcareous matter also produces flaws. The method recommended to prevent black core applies also to preventing calcareous flaws.

H. G. SCHURECHT

The effect of heat on the strength of calcined kieselguhr-portland cement mixtures. S. J. McDOWELL AND H. M. KRANER. *J. Am. Ceram. Soc.* 8, 784-8(1925).—Strength decreases rapidly at 100° , remains fairly const. between 200° and 500° , decreases slowly to about 800° , increases slightly between 800° and 1000° , and decreases further above 1000° .

C. H. KERR

Comparison of methods used in estimating the maturing of terra cotta. L. ANDERSON. *J. Am. Ceram. Soc.* 8, 762-7(1925).—Shrinkage trial pieces are more reliable than slip trials. Cones also should be used.

C. H. KERR

Metal porosimeter for determining the pore volume of highly vitrified ware. L. NAVIAS. *J. Am. Ceram. Soc.* 8, 816-21(1925).—The app. is of the McLeod-Gage type.

C. H. KERR

A laboratory kiln for obtaining high temperatures. F. H. NORTON. *J. Am. Ceram. Soc.* 8, 826-8(1925).—Describes a small gas-fired lab. kiln with temp. range up to 1850° .

C. H. KERR

The thermal expansion of refractories. F. H. NORTON. *J. Am. Ceram. Soc.* 8, 799-815(1925).—Contains much new and valuable information. The following table summarizes important characteristics:

Specimen no.	Type of brick	Melting point (reducing atm.)	Firing temp.	Mean coeff. $\times 10^{-7}$ of expansion between 0°C. and shrinking temp.	Max. coeff. $\times 10^{-7}$ of expansion between 300° and 700°	Max. irreversible contraction or expansion up to 1700°	Inversion points	Changes in slope	Temp. at which shrinkage or expansion begins

C. H. KERR

The examination of refractory materials and other aluminous substances. E. SCHÜRMANN AND W. BÖHM. *Chem.-Ztg.* **49**, 933-4, 958-9(1925).—A scheme of analysis is given to det. the constituents occurring in small amts. in the presence of large amts. of SiO_2 and Al_2O_3 . The finely powd. material is freed from SiO_2 by H_2SO_4 and H_2F_2 treatment, the bulk of the Al_2O_3 is removed by double pptn. as AlCl_3 from satd. HCl soln., the small remaining amts. being pptd. with the Fe and Ti by NH_4OH . The TiO_2 is sepd. by cupferron. The Fe_2O_3 , CaO and MgO are detd. by the usual methods in the absence of Ni and Mn. Small amts. of MgO are sepd. from the alkalis by Fresenius' HgO method. The alkalis are sepd. by K_2PtCl_6 . The detn. of S and P is not recorded. H. F. K.

Contribution to the study of refractories. V. BODIN. *Ceramique* **28**, 98-9(1925).—B. discusses clause 98 of the (French) marine on refractories. It is pointed out that refractories used by the marine must stand temps., varying from 1450° to 1650° in certain cases. H. G. SCHURECHT

The effect of variations in cupola practice on the life of refractory blocks. J. T. MACKENZIE. *J. Am. Ceram. Soc.* **8**, 720-34(1925).—The chief trouble noted is the injurious effect of oxidation resulting from thin or rusty scrap and from too high velocity of the blast. C. H. KERR

Operating conditions in the open hearth as they affect the life of refractories. C. A. SMITH. *J. Am. Ceram. Soc.* **8**, 833-8(1925). C. H. KERR

Refractory requirements in the gray-iron foundry. R. MOLDENKE. *J. Am. Ceram. Soc.* **8**, 712-9(1925). C. H. KERR

Principal refractory problems of the malleable-cast-iron foundry. H. A. SCHWARTZ. *J. Am. Ceram. Soc.* **8**, 708-11(1925). C. H. KERR

Rapid (density) method for determining the bauxite content of refractory brick. J. A. L. *Rev. mat. constr. trav. pub.* **193**, 236-7B(1925).—The apparent d. of clay products varies between 1.5 and 2.4, whereas the true d. (by powder method) is in the neighborhood of 2.67 and does not exceed 2.72. The apparent d. of bauxitic products varies between 1.9 and 2.2, while the true d. is between 3.1 and 3.2. By detg. the true d. of a material an est. of its bauxite content can be made, assuming that each addn. of 10% bauxite causes an increase in true d. of 0.005 above 2.72. The (1) apparent and (2) true d. of 3 refractory bricks exemplify: Belgian (1) 2.13, (2) 2.820; English, (1) 2.09, (2) 2.647; French (1) 2.18, (2) 2.643. The Belgian brick contains about 20% bauxite. LOUIS NAVIAS

A laboratory load furnace. P. D. HELSER. *J. Am. Ceram. Soc.* **8**, 822-5(1925).—An improved furnace for testing the load-carrying capacity of refractories. The advantages are: (1) direct application of load to specimen, (2) perfect alignment of specimen beneath load, (3) control of temp., (4) control of atm. in the testing chamber, (5) measurement of vol. changes throughout the test. C. H. KERR

New type of oxy-acetylene fusion furnace, with notes on the behavior of refractories at cone 40. A. F. GORTON AND W. H. GROVES. *J. Am. Ceram. Soc.* **8**, 768-73(1925). C. H. KERR

Effects of composition on the properties of sheet-steel enamels. H. G. WOLFRAM AND W. N. HARRISON. *J. Am. Ceram. Soc.* **8**, 735-55(1925).—Substituting feldspar for flint and flint for feldspar, also varying other constituents were studied. Coeff. of expansion is only one of the important factors. B_2O_3 and Na_2O used in place of some opacifier sometimes increases opacity. Replacing flint by feldspar increased resistance to edge-impact; decreased resistance to center-impact; decreased opacity; decreased resistance to both quenching and acid attack. In most cases replacing feldspar by flint increased resistance to quenching and to acid attack; decreased opacity; slightly decreased resistance to impact on edge and center. Enamels contg. both SiO_2 and feldspar were, on the whole, most satisfactory. C. H. KERR

A method for testing the cross-bending strength of enamels. R. R. DANIELSON AND W. C. LINDEMANN. *J. Am. Ceram. Soc.* **8**, 795-8(1925).—Impact tests are not entirely applicable to flat ware where strains are usually due to bending. A bending test device is described. C. H. KERR

The application of pebble or ball mills in enameling. E. W. LAWLER. *J. Am. Ceram. Soc.* **8**, 853-7(1925). C. H. KERR

Electrically annealed glass (ANON.) 4. Furnace for enameled articles (U. S. pat. 1,570,340) 1.

BERGE, AUGUST: *Chemische Technologie der Tonwaren*. Ein Repetitorium f. Keramiker. Halle (Saale): W. Knapp. 47 pp. R. M. 2.

Vitreous composition. E. C. BUCK. U. S. 1,570,202, Jan. 19. A vitreous compn. which is adapted for resisting HF and fluosilicic acid comprises a fused complex metaphosphate of Al and an alkaline earth metal substantially free from SiO_2 .

Glass-melting tanks. T. H. SWARTZLANDER. U. S. 1,569,152, Jan. 12.

Ophthalmic lens. E. D. TILLYER. U. S. 1,557,631, Oct. 20. In order to apply trade marks or other markings, a spot on the lens is subjected to a treatment (such as application of H_3PO_4 and heating) which causes it to react differently from the rest of the lens with respect to vapor, there being no change in the refractive properties of the lens except as caused by vapor.

Clay for ceramic articles. A. O. AUSTIN. U. S. 1,569,251, Jan. 12. Material for ceramic articles is prepd. in 2 portions, a dry portion and a portion rendered fluent by admixture of H_2O . These 2 are mixed together in such quantities that the mixt will contain somewhat more H_2O than is desired when the ceramic articles are molded and the excess H_2O is removed by evapn. to condition the material for molding.

Insulation bricks, etc. H. V. ALLEN. Brit. 234,538, Feb. 26, 1925. Bricks and blocks adapted for use in smelting furnaces, coke ovens and the like are made from a compn. of 80–87½% of coke breeze or dust and 20–12½% of a refractory clay, such as fire, ball, or china clay, or marl, mixed with H_2O , molded and burned to produce a porous product.

Glazing brick. A. FISCHER, JR. U. S. 1,570,137, Jan. 19. The surface of a normally non-conducting brick is heated to bring it into condition for conducting electricity, glazing material is applied to the heated brick and the material is fused by passing an elec. current through the surface of the brick and glazing material.

Kilns for burning bricks, etc. W. W. DICKINSON, JR. U. S. 1,569,952–3, Jan. 19.

Kiln for porcelain enameled ware, etc. H. B. CANNON. Brit. 234,049, May 14, 1924.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Cement manufacture and its possibilities in the Crown Colonies and protectorates.

IV. ANON. *Bull. Imp. Inst.* 23, 431–51 (1925); cf. C. A. 19, 879—Particulars are given relating to deposits of materials, which might be suitable for cement making, which have so far been discovered in British Malaya, North Borneo, Sarawak, Ceylon, Hong Kong, Palestine, Cyprus and Malta, with a discussion of the possibilities of cement manuf. in these regions.

A. PAPINEAU-COUTURE

The calculation of coal expenses in rotary cement kilns. D. A. TCHERNOBAIEFF. *J. Am. Ceram. Soc.* 8, 702–7 (1925).

C. H. KERR

Cement duct as manufactured and used in California. H. H. BUELL, R. P. LUTZ and H. C. MOYER. *J. Electricity* 56, 52–4 (1926).—Detailed description of the manuf. of these small cement "pipes."

C. G. F.

Studies of curing concrete in a semi-arid climate. HARRISON F. GONNERMAN and C. L. MCKESSON. Structural Materials Research Lab., Lewis Institute. *Bull.* 15, 37 pp. (1925).—Transverse breaking tests and surface-hardness tests by a ball-indentation method at ages from 3 to 90 days were made on $7 \times 10 \times 38$ -in. plain concrete beams cured out-of-doors by the following methods: (1) Covering with wet earth, (2) open air, (3) covering with asphaltic paper, (4) sprinkling surface with flake CaCl_2 , (5) brushing surface with sodium silicate solutions. These and test of changes of wt. during curing indicate that a curing method which prevents loss of moisture for 3 days or more is sufficient; 7- and 14-day wet-earth curing gave slightly better results at 90 days than 3-day wet curing. Methods (2) and (5) gave flexural strengths averaging about 80% of those obtained by method (1). Methods (3) and (4) gave intermediate flexural strengths.

RAYMOND WILSON

Siliceous limestone roads. LOUIS CABU. *Rev. universelle mines* 8 (7), 241–5 (1925).—A new type of material for surfacing roads consists of a thorough mixt. of sand, (350 l.), Na silicate (40 l. of d. 1.32) and crushed and previously moistened stone (1 cu. m.). The chief advantage is its great economy wherever limestone and Na silicate are available at low cost.

C. C. DAVIS

The durability of roofing slates. EINAR BOHR. *Industriidningen Norden* 54, 363–5 (1925).—The durability of various slate species of European origin is considered with special regard to their geological nature and chem. compn.

C. A. ROBAK

Corrugated building paper, its production and use. ANON. *Teer* 24, 5–7 (1926).—A brief discussion of its pressing, impregnation and use in construction.

W. B. P.

Roofing paper nomenclature. HEINRICH MALLISON. *Teer* **24**, 7-8(1926).—Favoring expressed distinction between papers prep'd. from tar pitch and from asphalt.

W. B. PLUMMER

Wood preservation. J. A. MARONIER. *Arch. Suikerind.* **33**, 1141-59(1925).—The economic aspects of the subject are discussed from the Dutch East Indian standpoint, and a description is given of the various methods in general use, with illustrations. Particularly good results have been obtained on various woods by the use of *Ombilin*, a coal-tar distillate contg. 66.7% PhOH, and higher phenols. It is applied at 85° with first a pressure of 6 atm. for 0.5 hr., followed by a vacuum of 43-43.5 cm. for 0.25 hr. The installation is simple and can be improvized in the sugar factory.

F. W. ZERBAN

Experiments carried out with the object of ascertaining the suitability of various kinds of woods for industrial chemical and metallurgical operations. J. K. STEWART. *Fruit Products J. and Am. Vinegar Ind.* **5**, No. 5, 33-5(1926).—Information on the following points was sought: change in vol., absorption of the solns., phys. deterioration, such as fiber destruction, weakening, etc.

J. A. KENNEDY

AMAR, CHARLES. *Théorie général et formulaire pratique du ciment armé.* Paris: Gauthier-Villars et Cie. 179 pp. Reviewed in *Le Génie Civil* **87**, 524(1925).

Cement tiles, etc. SOC. LAP. Brit. 234,846, May 30, 1924. In processes such as those of Brit. 217,605 (C. A. **19**, 387) and Brit. 222,500 (C. A. **19**, 1040) special aluminous cements are used to obtain somewhat translucent polished products. The special cements comprise silico-aluminous compds. in which the index ($\text{SiO}_2 + \text{Al}_2\text{O}_3$) ($\text{CaO} + \text{MgO}$) is greater than 0.6 and in which the proportion of Fe is less than 1.5%; or Ca aluminate, CaO , Al_2O_3 , contg. less than 5% impurities and less than 5% Fe. Fillers may be added.

Wet process of cement manufacture. G. POLYSIUS. Brit. 233,764, Feb. 11, 1924. The sludge is dried by waste gases from a rotary kiln, the drying, *e. g.*, being effected in a drum situated in the smoke box between the kiln and stack. Various structural details of the plant are described.

Cement and mortar materials. O. TETENS and REKORD-ZEMENT-INDUSTRIE GES. Brit. 234,233, March 25, 1924. Mixts. contg. siliceous, calcareous and bituminous ingredients are burned without addn. of fuel at temps. below the vitrifying point and with recovery of oil. The residue may be molded into bricks or ground for use as a cement.

Artificial stone. G. POLYSIUS. Brit. 234,302, June 24, 1924. Ground slag is mixed with unburnt gypsum or anhydrite, with or without sand, soda or CaO .

Artificial stone. J. THOMAS. U. S. 1,570,538, Jan. 19. A cementitious mixt. of semi-fluid consistency such as "Kcene's cement" is poured in successive layers with small quantities of colored dry cement or similar dry material on the surface of each layer to form veins or striations when the mass has hardened.

Plaster of Paris. E. L. WILSON. U. S. 1,570,583, Jan. 19. In producing plaster of Paris from pptd. gypsum, cryst. accretion is effected by subjecting the material to pressure to cause the crystals to coalesce, the coalesced crystals are converted into a non-compacted, interstitially extended mass, *e. g.*, by a shaving or crumbling, and this mass is uniformly calcined.

Cold glazes. C. J. TIDY. Brit. 234,707, Nov. 12, 1924. A cold glaze for cement, concrete and the like comprises a mixt. of port. cement, Al_2O_3 and a soln. of CaCl_2 , to which various pigments also may be added.

Color-blending filler for pavement cracks. H. C. HELMLE. U. S. 1,570,219, Jan. 19. A mixt. comprising crude rubber $1\frac{1}{2}$ -3, rosin 25-30, 37-40° B \acute{e} . distillate oil 1-4, TiO_2 0.05-0.5 and BaSO_4 0.1-1.0 lb., together with sufficient lamp black to give the desired shade of gray.

Macadamized roads. C. H. MURRELL and E. A. PHILLIPS. Brit. 233,776, Feb. 14, 1924. Road surfaces are repaired by distributing powd. or broken bitumen on them and pouring heated rock asphalt on the bitumen. Sufficient heat is utilized to cause adhesion of the materials and finely divided granite, chalk, "refuse," ground clinker or glass may be incorporated in the layer of asphalt.

Bituminous paving. J. H. AMIES. U. S. 1,570,028, Jan. 19. A one-tenth portion of a natural soil of the grade is heated by a blast heater to about 1100°. The remainder of the soil is macerated with boiling hot H_2O and the heated soil added. To each 9 cu. ft. of this highly heated mass there is added 20-30 lbs. of finely granulated quicklime, and finally, highly heated bituminous material.

Bituminous emulsions. H. A. MACKAY. Brit. 233,784, Feb. 14, 1924. Naphthene acid (with or without oleic acid or a similar fatty acid) together with hot H_2O and alkalis or alk. salts is used for emulsifying Mexican asphalt, pitch, or similar substances for use in road-making, briquets or as a waterproofing agent for stone, wood, roofing felt, etc.

Treating roads with bituminous substances. I. M. MUMFORD and T. S. BUTTERWORTH. Brit. 233,826, March 15, 1924. An aq. soln., *c. g.*, one contg. $NaHSO_4$ 10 and H_2SO_4 5%, capable of pptg. tar, pitch or the like from an aq. dispersion in which it is applied to a road, is spread on the road before the spreading of the bituminous dispersion.

"Artificial wood." A. FÖRSTER. U. S. 1,569,272, Jan. 12. A mixt. of sawdust and chalk or other soft mineral filler is moistened with a dil. soln. of chromate-glue in which the content of glue is considerably under 10%, the mixt. is worked and molded under high pressure and after the pressure is maintained for some time the product is dried.

Dyeing wood. H. RENNER. U. S. 1,570,575, Jan. 19. There is combined with the sap through the cellular tissue of wood, a mixt. of a coloring metal compd. such as $FeCl_3$ and $NaOAc$ in H_2O and a volatile or unstable substance in soln. or suspension, *c. g.* formic acid, forming salts for a time. The wood is dried out and the complex salts are decomposed and dyeing is effected by depositing permanent dyes fixed in the cells of the wood by the reactions which ensue.

Heating and chemical treatment of wood. H. D. P. HUIZER. Brit. 233,778, Feb. 14, 1924. Wood, *c. g.* plywood or the sheets for making it, is heated in a mold or between plates until it scorches and may be treated with dyes, "chemicals," metallic powders or fireproofing substances.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Production of coal (substitute) from wood. H. STRACHE. *Chem.-Ztg.* 49, 985 (1925); *Z. österr. Ver. Gas-u. Wasserfach.* 65, 183-4; cf. *C. A.* 20, 102.—Briefly describes the product of S.'s process (Lignizit) and repudiates newspaper claims that it would break the anthracite monopoly.

W. B. PLUMMER

New studies on brown coal. VII. The microchemistry of lignite. KAMETARO OHARA. *Braunkohle* 24, 817-9(1925).—A lignitized branch of *Taxodiioxylon sequanium* from lignite deposits at Owari (Japan) was studied. Extn. with boiling KOH soln. apparently removes the lignin, after which treatment the cellulose reaction with $H_2SO_4 + I$ is particularly distinct. With Sudan III sections were dyed uniformly, but after the color was completely removed by extn. with alc. the section could be dyed just as deep a color as before; the dyeing with Sudan III cannot therefore be considered a test for wax or resin. The lignin reaction with HCl -phloroglucinol could not be obtained. The results of other tests are described.

W. B. PLUMMER

Secondary pulverized-coal firing for stoker-fired boilers. MAX WEISS. *Braunkohle* 24, 833-6(1925).—A description with diagrams of installations for firing pulverized coal under stoker-fired boilers in order to meet peak loads.

W. B. PLUMMER

Results with electrostatic dust precipitation in the brown-coal-briquet factories of the Köln-Ost mining section. KARL EHRLING. *Braunkohle* 24, 813-6, 836-40 (1925).—A no. of actual and proposed installations are described with diagrams. None to date has apparently been entirely successful, particularly in avoiding dust explosions, but expts. are being carried on.

W. B. PLUMMER

The properties and constitution of coal ulmins. Studies in the composition of coal. WILFRED FRANCIS and R. V. WHEELER. *J. Chem. Soc.* 127, 2236-45(1925).—In continuation of work showing that alkali-insol. ulmins are made alkali-sol. by oxidation (cf. *C. A.* 19, 1484), the reactions were studied by analytical means. No fundamental change occurs in the ulmin mol. by such oxidation with H_2O_2 or air at 150° , but the external groups are modified, those more readily detached being eliminated as simple oxygenated compds. and their place being taken by carboxylic groups. The internal (nuclear) structure of the mol. of the sol. ulmins is identical with that of the insol. matrix of unoxidized bituminous coal and a knowledge of the former allows an insight into the latter. The change from insol. to sol. ulmins is gradual, a moderate degree of oxidation changing the external groups enough to render the matrix of coal difficultly sol. in alkalis. As oxidation proceeds, more groups are eliminated and the ulmins become more acidic and more sol. in alk. and neutral solvents. The limit with air at low temps. is

reached when all external groups are eliminated (cf. Pearson, *C. A.* **17**, 1876), but H_2O_2 or HNO_3 decomposes the nucleus of the ulmin mol. Because oxidation is gradual, the sol. ulmins are not homogeneous and can be sepd. by fractional soly. in different solvents. The CO_2H groups formed by oxidation allow the formation of salts, insol. *Ba*, *Fe*, *Ag* and *Cu* salts of *alkali-sol. ulmins* being prepd. Hydroxyl groups also were identified in the sol. ulmins in an amt. corresponding to 1 OH per mol. wt. of 680, the latter unit also contg. $4\text{CO}_2\text{H}$ groups. The N content increases with increase in soly. of the ulmins until the whole coal matrix is sol., and indications point to N as an essential constituent of the ulmin mol. nucleus. This suggests both an important role of N and the occurrence of the Maillard reaction (*C. A.* **10**, 2577; **11**, 2010) in the formation of coal ulmins. In coal formation, sugars may be derived from the cellulose of the cell walls by enzymes or bacteria and the amino acids from polypeptides in the cells. Destructive distn. of sol. ulmins gave at $160\text{--}70^\circ$ a gas contg. CO_2 and CO in the ratio of 12:1, this ratio increasing to 300° and then decreasing. H and satd. hydrocarbons appeared first at 450° . H_2O was evolved at low temps. and a trace of an oil at 550° , the results resembling those of peat ulmin (cf. Tidswell and Wheeler, *C. A.* **17**, 1121) and confirming the earlier work (*C. A.* **19**, 2484) that the matrix of durain is much the same as that of vitrain. Extreme action of H_2O_2 on sol. ulmins yielded H_2O , CO, CO_2 and all N as NH_3 . Intermediate action gave aliphatic dibasic acids, including oxalic and succinic acids, and benzenepolycarboxylic acids. Dil. HNO_3 yielded 25% (based on the sol. ulmin) of H_2O -sol. products, comprising aliphatic dibasic acids, aromatic acids and nitrophenols, of which were identified oxalic, succinic, picric, pyromellitic and probably trimellitic acids. Picric and pyromellitic acids proved the presence of benzenoid rings in the nucleus of sol. ulmin mols. and hence in the matrix of bituminous coal. The further presence of oxalic and succinic acids indicates that the nuclei of the ulmin mols. (which comprise the bulk of all bituminous coals) are compact systems of benzenoid groups bound by heterocyclic rings, such as pyrrole and furan or their derivs. C. C. DAVIS

The application of X-rays to the determination of the washing properties and to the control of washing operations of coal. MACLAREN. *Rev. ind. minérale* No. 121, Pt. 2, 1-12, Jan. 1, 1926.—A description of recent developments (cf. *C. A.* **19**, 3362) with numerous illustrations of X-ray app. and photographs of coal. C. C. DAVIS

What prospects does the Bergius process offer for the German oil supply? MANFRED DUNKEL AND MYRON HEYN. *Naturwissenschaften* **13**, 1021-4 (1925).—A review. The process is considered the most valuable and important invention in the field of coal treatment. B. J. C. VAN DER HOEVEN

The melting point of ashes and its relation to their analytical composition. P. GRANDJEAN AND A. ROTHUN. *Chaleur et industrie* **6**, 530-5, 582-91 (1925).—After a brief review of present methods of detg. the m. p. of ashes, G. and R. propose a new method based on the triangular diagram of the quaternary mixt. $\text{SiO}_2\text{--Al}_2\text{O}_3\text{--CaO--FeO}$, or even of the ternary mixt. $\text{SiO}_2\text{--Al}_2\text{O}_3\text{--FeO}$ when Raoult's law can be applied to the CaO soln. (not over 5% CaO). From the diagram one can obtain the points of complete fusion and of incipient fusion; and the "softening point" as measured by a Seger cone depends mainly on the viscosity of the cone, which in turn depends on the quantity of liquid contained in the mass of the cone when it falls. It is suggested that the softening point be defined as the temp. at which $n\%$ of the ash is liquid, and n may be chosen so that the value of the softening point may be as close as desired to what is now generally called the m. p. The effects of the other constituents of ashes (mainly MgO and alkalis), considered as impurities, are discussed. A. PAPINEAU-COUTURE

The problem of the national [Italian] motor fuel with alcohol as a base. LUIGI DAL PRATO. *Rass. min. met. chim.* **63**, 136-40 (1925).—Comparative automobile performance tests of 6 different com. fuels contg. the following vols. % of EtOH, benzene, benzene and Et_2O , resp.: (1) 40, 60, 0, 0; (2) 38, 40, 20, 2; (3) 40, 30, 25, 5; (4) 50, 44, 0, 6; (5) 76, 20, 0, 4 and (6) 0, 100, 0, 0 showed (4) to be practically the equiv. of (6) and to be superior to (1), (2), (3) and (5). The power output varied inversely with the calorific power. See also Garelli, *C. A.* **19**, 1488. C. C. DAVIS

Present status of the facts and theories of detonation. GEO. G. BROWN. *Ind. Eng. Chem.* **18**, 213 (1926).—Polemic. Cf. Clark and Thee, *C. A.* **20**, 273. Answer. G. L. CLARK. *Ibid* 213. E. J. C.

The theory of anti-detonants. HENRI MURAOUR. *Chimie et industrie* **14**, 851 (1925).—M. suggests that anti-detonants act by formation of a cloud of solid particles which attract part of the ions of the explosive mixt. and reduce the rate of the reaction below the detonating point (cf. Malinovskii, *C. A.* **19**, 1630). This would also explain

why anti-detonants also act as anti-flashes. Exptl. verification of the hypothesis would be desirable. A. PAPINEAU-COUTURE

Purification distillation of crude anthracene by the addition of gas oil. A. WOLFRUM. *Chem. App.* 12, 241-2(1925).—The oil should be carefully fractionated and should contain very little boiling outside the limits of 260–310°, should contain but little solid paraffins and oil boiling between 305–330° and should hold back in soln. not over 2–3% of the substance to be purified. The amt. of oil used should be 2–3 times the wt. of the substance. Description and cut of app. are given. J. H. MOORE

Behavior of grate bars in the fire. ROBERT STUMPER. *Chaleur et industrie* 6, 549-54(1925).—A detailed discussion of the effects of the chem. compn. and metallographic constitution of the bars, of the chem. compn. of the fuel, of the condition of the fire and of the kind of boiler, from which S. concludes that white Fe is much better than gray Fe for the purpose. A. PAPINEAU-COUTURE

The combustion process as the basis for industrial gas utilization. F. PLENZ. *Gas u. Wasserfach* 69, 1-4(1926).—A discussion of the application of our knowledge of flame temps., flame propagation velocities, etc., to problems of industrial gas utilization. W. B. PLUMMER

Heating control by analysis of combustion gases. R. CAILLLOL. *Technique moderne* 18, 13-9(1926).—Description of various flue-gas-analyzers, and a discussion of the value of the indications which they give. A. PAPINEAU-COUTURE

Correction to Boyle's law for high-pressure gas. D. E. SILCOX. *Mech. Eng.* 47, 897-900(1925).—Graphs and tables show the deviation of natural gas from Boyle's law with change of pressure, temp. and gasoline content. In extreme cases such as natural gas high in ethane and under pressures up to 400 lbs. this deviation may reach 20%. H. L. OLIN

The present situation in gas street lighting. WILHELM BERTELSMANN. *Gas u. Wasserfach* 68, 819-24(1925).—Descriptions, tabulations of gas consumption and illuminating power, etc., for various types of mantles and arrangements of mantles for street lighting. W. B. PLUMMER

Scrubbing carbon dioxide from gases by water under pressure. ANON. *Gas u. Wasserfach* 68, 833(1925).—A brief discussion. W. B. PLUMMER

The evolution of the manufacture of illuminating gas toward the increase in the production of gas and the reduction of gas-house coke. A. GREBEL. *Le Genie Civil* 87, 245-9(1925). JACK J. HINMAN, JR.

Safety devices in gas generator installations. KARL KREKELER. *Braunkohle* 24, 840-4(1925).—A discussion of the location and construction of explosion safety vents. W. B. PLUMMER

Methods and apparatus for ammonium sulfate production. A. THAU. *Gas u. Wasserfach* 68, 799-805, 824-9(1925).—A detailed discussion of saturators, NH₃ stills, sulfate driers and conveying equipment, etc. and of special processes for NH₃ recovery such as the CaCl₂ and CaSO₄ processes. Diagrams are given of 11 different types of saturators. W. B. PLUMMER

The influence of water vapor and hydrogen chloride on the velocity of decomposition of ammonia. A. SCHMIDT. *Z. angew. Chem.* 38, 1146-54(1925).—In the decompn. of dry NH₃ in a porcelain tube, the velocity of decompn. is greatly accelerated during the course of the expt. This acceleration is parallel with the sepn. of metallic Fe from the tube, which is due to the reducing action of the decomposed NH₃. H₂O vapor, in sufficient concn., prevents the sepn. of Fe and stops the decompn. which has initially been accelerated by Fe. HCl acts in a similar manner and at high temps. forms FeCl₃. Expts. with coke show that the decompn. of NH₃ is slower when H₂O or HCl is present. It is, therefore, probable that the increase in the NH₃ yield in the gasification of fuel in the presence of H₂O or HCl is due to the fact that the formation of Fe (which would greatly accelerate the decompn. of NH₃ catalytically), is prevented. J. H. PERRY

Ammoniacal liquor and noxious effluents from distillation plants. J. W. YOUNG. Annual Report of Alkali etc., Works Inspector. *Gas World* 82, 647-50(1925).—This report discusses several noxious effluents and methods employed for removal and to prevent their formation. Liquors from vertical retort systems are highly charged with higher tar acids, color-producing substances, etc. Liquors from horizontal retort plants were relatively free from such substances. Phenol is considered to be the most noxious constituent in effluents. Its removal is effected by scrubbers in which flue gases are injected into the base of the scrubber, the injector working at a steam pressure of 70 lbs. Liquor enters at 91° and leaves at 95°. A phenol volatilization efficiency of 94% and reduction in O-absorbing figure of 34% is claimed. The content of thiocyanate, thio-sulfate, etc., is reduced by reducing the O and cyanide content of the crude gas and by

protecting the liquor against air during storage. Liquor stored in contact with tar or allowed to stand in contact with air gives a high figure for total O absorbed. The removal of 90-95% of tar from oven gases has been accomplished by spraying with liquor, thus reducing the temp. of the gases from 130-135° to 70-75°. Expts. show that free NH_3 in liquor favors emulsification of tar and the extn. of O-absorbing constituents from the tar, while fixed ammoniacal salts have a contrary effect. A. E. G.

Steam generation in 1925. DAVID BROWNLIE. *Chemistry & Industry* 45, 21-2 (1926). E. J. C.

Rich and lean gas for gas forging and welding. D. HUDLER. *Gas u. Wasserfach* 68, 812-4 (1925).—Comparisons from the standpoints of heat available, heat capacity of the combustion products, etc. W. B. PLUMMER

Water-gas tar. A. L. FRANKENBERGER. *Am. Gas J.* 124, 24-5 (1926).—A description of the operation and results of steam-heated settling and boiling tanks at 3 plants. Dehydration costs were 0.91-1.55 cents/gal., of which 0.74-1.22 cents is labor cost. W. B. PLUMMER

By-product coke and gas industry. C. J. RAMSBURG. *Blast Furnace & Steel Plant* 14, 13-4 (1926).—A review for 1925. E. J. C.

Rational improvements in the technic of by-product coking. H. SCHELAUSKE. *Teer* 24, 1-5 (1926).—A brief description of the Feld process for fractional condensation of tar direct from the raw gas (cf. C. A. 19, 165, 2739) and a discussion of its application to various types and sizes of plants. W. B. PLUMMER

New results with the Still coke oven. H. KUHN. *Gas u. Wasserfach* 69, 5-11 (1926).—The distinctive feature of the Still oven is that combustion in the vertical heating flues is multi-stage. A small air-inlet flue is located between each heating flue and air admitted to them through 4 openings in each of its sides. The walls of the oven are thus heated uniformly from top to bottom. Detailed data are given of gas consumption, wall temps., etc., for 2 installations of these ovens. In one case the ovens proper were 3.0 m. high \times 0.41 m. av. width (18-hr. coking time), in the other 2.55 m. high \times 0.48 m. av. width (26-hr. coking time). W. B. PLUMMER

Gas washing (WEISSENBERGER, et al.) 13. Calculation of the various factors in drying, with reference to brown coal (DEIMLER) 13. Determination of H and CH_4 in illuminating gas (PERNECKER) (OTT) (STUEVER) 7.

STEINERT, JOHANNES: *Der Torf und seine Verwendung*. Berlin: de Gruyter & Co. 149 pp. R. M. 1.25.

Fuel mixture. C. J. HOOVER. U. S. 1,570,585, Jan. 19. A fire-kindler comprises charcoal 8, granulated sawdust 60, lycopodium 2 and crude turpentine 30%.

Fuel for internal-combustion engines. R. H. MCKEE. U. S. 1,570,161, Jan. 19. A homogeneous mixt. is formed from the gasoline-like fraction of shale oil, com. C_6H_6 (contg. toluene), alc., and C_2H_4 2-8%. The use of C_2H_6 also is referred to.

Fuel for internal-combustion engines. G. HAMMOND. U. S. 1,570,059, Jan. 19. Kerosene is mixed with about 30% its quantity of gasoline or other light, freely ignitable hydrocarbon material and with small quantities of acetone, glycerol and BuOH . U. S. 1,570,060 specifies a mixt. of kerosene 40-50, gasoline 50-60, BuOH 1-4 and C_6H_6 3-12 parts.

Fuel briquets. R. TORMIN. Brit. 234,805, May 28, 1924. Coal or coke or similar material to be briquetted is treated with 1% or more of C_6H_6 , toluene, CS_2 , or similar solvent which is partially recovered in the pressing operation and causes the bitumen content to be distributed in the fuel mass. Pitch or other bituminous material may be added to "poor" coal.

Treating coal. W. E. TRENT. U. S. 1,570,103, Jan. 19. Finely divided coal together with a fluxing agent such as CaO , Fe_2O_3 , or Na_2CO_3 is introduced into a current of gas and passed through a heat zone to remove volatile by-products from the coal and cause a union of the ash-forming constituents and fluxing agent. The purified C content of the coal is then recovered.

Treating coal-washing water. R. A. BURROWS, F. S. SINNATT, L. SLATER and N. SIMPKIN. Brit. 233,842, April 1, 1924. Suspended materials in water used for washing coal are sepd. by addn. of a coagulating or flocculating agent such as lime, NaOH , $\text{Al}_2(\text{SO}_4)_3$, Na aluminate, MgCl_2 , Na silicate, silicic acid, silica sol, casein, glue, gelatin, Na stearate or albumin. The mixt. is allowed to settle with as little agitation as possible.

Extracting oils, waxes, etc. from coal and similar materials. H. NOVAK and J. TREBICKY. Brit. 234,564, March 6, 1924. Tetrahydronaphthalene, decahydronaphthalene, hexahydrophenol or other hydrogenated products of $C_{10}H_8$ or $PhOH$ are used to break down coal, anthracite, peat, lignite, bituminous slates and similar materials *e. g.*, by prolonged application of their vapors. Solvents such as C_4H_8 and acetone may also be used to assist in extg. oils, waxes and other substances.

Retort or oven for distillation of coal, shale, etc. (spreading and scraping mechanism). W. N. GRANT. U. S. 1,569,478, Jan. 12.

Dry distillation. J. J. DESCHAMPS. Brit. 234,840, May 30, 1924. In gas retorts, coke ovens and the like, pulsations are produced in the reaction chamber by periodical injections of vapors or gases into the discharge current. The addn. of gas or vapor or purified coal gas facilitates the purification of the gas produced and removes the risk of tar being deposited in the pulsator itself. H and H_2O vapor may be used.

Gas producer. BISMARCK-HÜTTE. Brit. 234,114, May 13, 1924.

Gas producer. S. A. MOSS. U. S. 1,570,314, Jan. 19.

Proceedings of a conference to determine whether or not there is a public health question in the manufacture, distribution or use of tetraethyl lead gasoline. ANON. U. S. Pub. Health Service, *Pub. Health Bull.* 158, 116 pp.(1925).—This is a record of the testimony submitted by industrialists and public health officials and investigators regarding the history of tetraethyl lead in relation to gas engines; its manuf., distribution, and transportation; the exptl. and clinical data on toxicity; and its public health aspects. Expts. on animals in 4 sep. investigations indicate that a hazard exists wherever tetraethyl lead is made or used, but there is a wide divergence of opinion as to whether the hazard is great enough to warrant prohibition. Many city and state health officials have investigated in districts where millions of gal. of ethyl gasoline were being consumed in automobiles, and could find no evidence upon which they could logically base a prohibition regulation; but frankly admitted the need for national leadership, especially in regard to the interpretation of the fact of the extremely slow cumulative effects of very small quantities of Pb compds. After assembling all the available facts, the conference adopted the following resolution: "It is the sense of this conference that the Surgeon General of the U. S. Pub. Health Service appoint a committee of 7 recognized authorities in clinical medicine, physiol. and industrial hygiene, to present to him, if possible, by Jan. 1 next, a statement as to the health hazard involved in the retail distribution and general use of tetraethyl lead gasoline motor fluid; and that this conference indorses as wise the decision of the Ethyl Gasoline Corporation to discontinue temporarily the sale of ethyl gas; that this investigation shall be paid for exclusively out of public funds; and that the results of this investigation shall be reported back to a pub-

lic conference called for the purpose by the U. S. Pub. Health Service, at which labor shall be represented." (ABSTRACTOR'S NOTE.—The Surgeon General appointed Julius Stieglitz, W. H. Howell, Reid Hunt, D. L. Edsall, C. E. A. Winslow, W. S. Leathers and A. J. Chesley who reported on Jan. 17, 1926 that no good grounds exist for prohibiting the use of ethyl gasoline in automobiles, although employees of com. garages may be exposed to a slight lead hazard. No evidence of danger to the general public was found. The Ethyl Gasoline Corporation expects to resume the national distribution of ethyl gasoline.) C. M. SALLS

The effects of the tetraethyl lead upon the deterioration of turbine oils. SIRŌZI HATTA. *J. Soc. Chem. Ind. Japan* **28**, 1346-52(1925).—On the assumption that the deterioration of turbine oils is due mainly to the oxidation of the components of the oils by the action of heat and air, Et_4Pb was used as an anti-catalyzer of the oxidation. 0.05, 0.1 or 0.2% of Et_4Pb was added to pure oils and kept at 120° ; moist O_2 was passed in at the rate of about 150 bubbles per min. Samples were taken at definite time-intervals for testing color, sp. gr., viscosity, acid and sapon. values, amt. of sludge, and the Herschel deëmulsiivity. When an oil of the paraffin series was used, the darkening of the color, the sludge formation, and the deterioration of deëmulsiive power were distinctly decreased by the presence of Et_4Pb . The sp. gr., viscosity and acid and sapon. values of the oil were, however, independent of the presence of Et_4Pb . The sp. gr., viscosity and acid and sapon. values of the oil were, however, independent of the presence of Et_4Pb , all increasing gradually. As to oils of the naphthenic series, the result was of an opposite nature, except that the darkening of the color was retarded; the sp. gr., acid and sapon. values and the sludge formation were all distinctly increased by the presence of Et_4Pb . K. KASHIMA

Methods of testing transformer-oils. H. C. STARGER. *Ind. Eng. Chem.* **17**, 1272-5(1925).—Several of the commonly used tests are discussed critically. The "BBC" test (Brown-Boverie Co., Switzerland) is defended as the most useful test for detg. the quality of transformer oils (cf. *C. A.* **17**, 1851, 2639; **18**, 164). W. F. F.

Transformer and switch oils. D. V. ONSLOW. *World Power* **5**, 37-41(1926).—A review including chapters on viscosity, flash point, sludge, etc. C. G. F.

The constitution of Swedish generator shale oil. GUSTAV HELLSING and J. S. W. TROEDSSON. *Arkiv Kemi, Mineral. Geol.* **9**, No. 22, 12 pp.(1925).—Previous investigations carried out upon the constitution of shale oil obtained from dry distn. of Swedish alum shale on a small scale (*C. A.* **15**, 3552), has prompted the present work on shale oil produced on a factory scale in specially constructed gas generators. The product investigated was the unrefined fraction of the crude oil b. $150-300^\circ$. After preliminary treatment with H_2SO_4 and KOH and several fractionations finally a fraction b. $150-185^\circ$ was collected, amounting to 0.99% of the starting material. This fraction was oxidized with KMnO_4 , the oxidation loss being 17.5% (unsatd. compds.). The oxidized oil was subjected to a fractional distn. and the $155-185^\circ$ fraction was sulfonated, the sulfonation loss being 60.67% (sulfonated compds.). This was converted into Na sulfonates and these in turn into sulfonic acid amides, which after recrystn. from alc. Et_2O had a sharp m. p. 175° . The product was *pseudocumenesulfonamide*. From the oxidation and sulfonation losses it is concluded that generator shale oil is lower in unsatd. hydrocarbons and higher in aromatic hydrocarbons than shale oil obtained by direct dry distn., where the losses were 31.0 and 33.0%, resp. The unsulfonated oil consists mainly of naphthenes, in particular *decanaphthenes*, $\text{C}_{10}\text{H}_{20}$ b. $160-175^\circ$, and *hendecanaphthene*, $\text{C}_{11}\text{H}_{22}$, b. about 180° . Nitration of the unsulfonated part of the oil formed some $\text{H}_2\text{C}_2\text{O}_4$. Bromination of the nitrated oil yielded a heavy oil, probably $\text{C}_{10}\text{H}_{18}\text{NO}_2\text{Br}$. Direct bromination of the unsulfonated oil in a closed tube yielded a distinctly cryst. compd., probably 2,4,6,1,3,5- $\text{Br}_3\text{C}_6\text{Me}_2\text{Et}$, the parent substance thus being *β -decanaphthene*. The genetic relation of naphthenes and aromatic hydrocarbons in shale oil is discussed. D. THURSEN

Charts for studying the oil film in bearings. GEO. B. KARELITZ. *Mech. Eng.* **48**, 128-31(1926). E. J. C.

Substitutes for spirits of turpentine: hydroterpinol and other products derived from pine oil. J. H. FRYDLENDER. *Rev. prod. chim.* **28**, 829-35.—Review of its properties and method of prepn., based on recent German patents and literature. A. P.-C.

Petroleum in Poland (PAZDRO) 8. Gas washing (WEISSENBERGER, et al.) 13. Retort or oven for distillation of shale (U. S. pat. 1,569,478) 21. Extracting oils, waxes, etc., from coal and similar materials (Brit. pat. 234,564) 21.

Refining mineral oils. J. C. MORRELL. U. S. 1,569,870, Jan. 19. Oil is treated with an aq. soln. of alkali metal plumbite and, after sepn. from the plumbite soln., is further treated with Ca, Al or Mg sulfide or other sulfide capable of hydrolyzing in H_2O . The pptd. material and sulfide are then sepd. from the oil. U. S. 1,569,871 specifies treating oil with Na plumbite in aq. soln., sepg. the plumbite soln., treating the oil with an aq. sulfide soln., withdrawing the reaction products, and then further treating the oil with a flocculating agent such as dil. H_2SO_4 or HCl and sepg. pptd. material. U. S. 1,569,872 specifies treating oil such as cracked distillate (previously treated with H_2SO_4 , NaOH and H_2O) with alkali metal plumbite in aq. soln., agitating, sepg. the plumbite soln., treating the oil with sulfide in aq. soln. and removing the sulfide and reaction products.

Cracking petroleum oils. R. B. DAY. U. S. 1,570,131, Jan. 19. A first treatment chamber is maintained constantly full of liquid oil while a pool of oil is maintained in a second chamber at a level over the first chamber and constantly connected by a communicating body of the liquid with the oil in the first chamber through a column of oil extending from the interior and top of the first chamber to the interior and bottom of the second chamber. Sufficient heat is applied to the exterior of the first chamber to crack some of the oil in it and aeriform products are led off from above the pool of oil. Even heating within the first chamber is effected and deposition of C on its walls is prevented by violently agitating the liquid material.

Bleaching, "cracking," and desulfurizing petroleum. HERMAN REINBOLD and HUGO REINBOLD. U. S. 1,570,005, Jan. 19. Hydrous silicic acid together with metal chlorides such as $AlCl_3$ (produced from bentonite and HCl) are used for refining, distg. and "cracking" or converting oils. Cf. C. A. 20, 108.

Distilling hydrocarbon oils. G. EGLOFF and H. P. BENNER. U. S. 1,569,855, Jan. 19. Oil vapors produced in a still are passed through a filtering bed which may be formed of fuller's earth, boneblack or charcoal and which is located in the vapor space of the still above the oil level and above the oil inlet of the still. The vapors are subjected to dephlegmation, uncondensed vapors being led off to a condenser and reflux condensate being returned to the still below the filter bed.

Cracking and "converting" hydrocarbon oils. H. R. BERRY. U. S. 1,569,532, Jan. 12. Oil is continuously introduced into an enlarged zone or chamber together with a continuous supply of undil. steam in such vol. and at such temp. that the C released by the cracking is converted into C oxides by the action of the steam so that C deposition on the walls of the reaction chamber is avoided.

Recovering oil from oil-bearing sands. D. C. COLLIER. U. S. 1,570,205, Jan. 19. Oil-bearing material is mixed with H_2O and with subdivided coal, coke or other carbonaceous material and the mixt. is subjected to agitation so that the oil and carbonaceous material are agglomerated and float on the H_2O while the sand settles out.

Apparatus for de-emulsifying petroleum oils, etc. by filtration through oil-treated diatomaceous earth. C. V. ZOUL. U. S. 1,569,695, Jan. 12.

Distilling shale or other carbonaceous materials. R. M. CATLIN. U. S. reissue 16,252, Jan. 12. See original pat. No. 1,509,667, C. A. 18, 3713.

Extracting vanadium from petroleum hydrocarbons. A. OBERLE. U. S. 1,570,170, Jan. 19. Petroleum material such as still residue is heated to drive off volatile substances and the residue is subjected to a leaching operation with a V solvent such as H_2O and steam to recover the V compds. from it.

"Commercial gasoline" from natural-gas gasoline. H. J. MACKENZIE and A. W. STEENBERGH. U. S. 1,569,433, Jan. 12. Gasoline-contg. gas is compressed, cooled to normal temp. while the compression is maintained and the resulting "natural-gas gasoline" is sepd. under pressure. It is then mixed with blending gasoline and the mixt. is cooled under pressure and the pressure then released to atm. pressure, gas sepd. from liquid and the temp. is gradually brought to atm. temp. to permit a progressive sepn. of gas from liquid.

Separating paraffins from liquid hydrocarbons. AKTIEBOLAGET SEPARATOR-NOBEL. Swed. 60,012 and 60,013, Dec. 22, 1925. The paraffins pptd. by cooling are sepd. from the liquid hydrocarbons by centrifugalizing after the sp. gr. of the liquid first has been lowered by addn. of a separately cooled diluent of lower sp. gr. than the paraffins. Cf. C. A. 19, 2562.

Treating bituminous substances to remove sulfur. G. W. ACHESON. U. S. 1,570,193, Jan. 19. Bituminous material such as crude S-contg. oil is treated with a reflocculated solid adsorbent material, e. g., reflocculated clay and H_2SO_4 . A S-contg. ppt. is sepd. from the material.

Electric separation of petroleum emulsions. J. H. C. DE BREV. U. S. 1,570,209,

Jan. 19. Petroleum emulsions are treated with a pulsating a. c. having a peak voltage which is "a multiple of the effective voltage."

Purifying lubricating oils in internal-combustion engines. W. B. CLIFFORD. Brit. 234,082, May 16, 1924. A thermostatically controlled by-pass and vaporizer heats and purifies the oil at a temp. slightly below its flash point. The vaporizer is heated by the exhaust from the engine.

Apparatus for reclaiming asphalt, etc., from waste materials. R. D. DIVINE. U. S. 1,569,462, Jan. 12.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Depolymerization of cellulose. EMIL HEUSER AND NORBERT HIEMER. *Cellulose-chemie* 6, 101-22, 125-32, 153-66(1925).—A comprehensive study of the degree of polymerization (*i. e.*, aggregation) of alkylated cellulose prepd. from physically different celluloses. The following materials were used in the prepn. of various methylated celluloses: purified cotton; cellulose regenerated from cuprammonium solns. by CO_2 ; artificial silk prepd. by the cuprammonium process; "hydrocellulose" prepd. by the action of HCl gas on the same; viscose pptd. by adding a ripened xanthate soln. to boiling H_2O ; an alkali-sol. "hydrocellulose" formed from viscose silk on treatment with HCl gas for 3 hrs.; a "hydrocellulose" prepd. by further treatment of the latter with HCl for 50 hrs.; "cellulose A," a product formed by Hess and Weltzien's method (*C. A.* 18, 1385) from the corresponding acetate; "cellodextrin I" prepd. by dissolving cellulose in 72-74% H_2SO_4 pptg. (after 1 hr.'s standing) with EtOH and finally heating with alc. to insure hydrolysis of cellulose sulfates; "cellodextrin II" prepd. by a method similar to that used in the preceding prepn., except that the pptn. with alc. occurred after the acid soln. had remained standing for 10 hrs. In general it was found best to limit methylation with a view towards obtaining a product contg. 2-2.5 Me groups for every 6 C atoms. The products therefore ranged from 32 to 39% MeO and were partially or completely sol. in cold H_2O . Trimethylcellulose prepn. are much more insol. in H_2O and are unsatisfactory for use in mol. wt. detns. Normally, the milder the treatment of the cotton prior to methylation (1) the lower the soly. of the Me deriv. in cold H_2O (2) the higher the mol. wt. of the methylated product, (3) the higher its "softening point (Erweichungstemperatur), and (4) the greater the number of methylations required to effect complete methylation of the cellulose. Those methylation products which are sol. in cold H_2O are usually repptd. on heating the soln. and may be partially purified in this way. However, with an increasing "degree of depolymerization," the methylcelluloses become increasingly sol. in warm H_2O . The degree of depolymerization of cellulose ("depolymerisationsgrad") is defined as the mean mol. wt. of the dimethylated product divided by 190 (190 being the mol. wt. of $[(\text{C}_6\text{H}_5\text{O}_2)(\text{OMe})_2]$). There appears to be no correlation between the Cu no. (Schwalbe) and the degree of depolymerization. Heuser's and Hiemer's results indicate that every depolymerization product of cellulose is characterized by a series of properties which, in most cases, change regularly with the degree of depolymerization. The period of complete methylation of cellulose is greatly shortened by acetylation of the dimethyl deriv. of viscose. The monoacetyldimethylcellulose (2.5 g.), when treated with 50 g. NaOH in 50 cc. H_2O and 60 cc. Me_2SO_4 at 60° (in the presence of small quantities of EtOH) followed by treatment with 45 g. NaOH in 45 g. H_2O and 30 g. Me_2SO_4 gave rise to a methylcellulose contg. 44.3% MeO in a single operation. One further methylation in the presence of solid NaOH (5 g.) yielded trimethylcellulose (contg. 45.4% MeO; theory = 45.6%). Cellulose triacetate prepd. from cotton linters in 2-phase methylation yielded a product contg. 38.3% MeO, on further methylations gave a trimethylcellulose (contg. 45% MeO), m. $220-5^\circ$, fairly sol. in cold H_2O and completely sol. in AcOH and CHCl_3 .

LOUIS E. WISE

Dispersoidological investigations. VI. Quantitative study on cellulose dispersion in concentrated aqueous solutions of strontium thiocyanate, strontium bromide and strontium chloride. P. P. VON VEIMARN AND K. AOKI. *Reports of the Imp. Ind. Research Institute, Osaka, Japan* 6, No. 10, 11-33(1925); cf. *C. A.* 19, 3589.—Expts. on dispersion of 1 g. of cellulose (No. 292 tablets filtering mass, Schleicher and Schüll) in 100 cc. of aq. solns. of $\text{Sr}(\text{CNS})_2 \cdot 3\text{H}_2\text{O}$ satd. at 25° , at 50° and at 75° were carried out at definite temps. ranging from 130° to 160° , 170° or 180° (depending on the concn. of salt). The dispersion curves (drawn by plotting temps. against time periods required for complete dispersion) are of the normal type. Velocity of dispersion increases with rising temp. If the temp. is kept const. the velocity of dispersion

increases with increasing concn. of salt. Expts. were also carried out at 150°, 165° and 180° with the same concns. of $\text{Sr}(\text{CNS})_2$ and definite vols. of soln., the amts. of cellulose added being varied. Again the rate of dispergation increased with increasing temp. and increasing concn. of salt. The larger the amt. of cellulose added the longer the time required for complete dispergation. This is illustrated by dispergation curves (drawn by plotting wt. of cellulose against time required for complete dispergation). A series of excellent ultraphotomicrographs indicates the remarkable swelling of the cellulose prior to complete dispergation. Expts. on the dispergation of cellulose in aq. SrBr_2 showed that at a definite temp. the velocity of dispergation increased with concn. of the salt. The rate of dispergation also increases rapidly with increasing temp. (and pressure) in the SrBr_2 solns. The swelling of the fibers is less marked than in the case of $\text{Sr}(\text{CNS})_2$ soln. and the rate of dispergation is much slower. Even after heating 0.5 g. of cellulose in 100 cc. of aq. SrCl_2 (satd. at 125°) for 15 hrs. no complete dispergation occurred. VII. Quantitative study on cellulose dispergation in concentrated aqueous solutions of barium thiocyanate and barium bromide. P. P. VON VEIMARN AND S. KATAOKA. *Ibid* 37-44.—100 cc. of $\text{Ba}(\text{CNS})_2$ soln. kept at 128-130° with free access of air completely dispergated 1 g. cellulose in 13-14 hrs. On cooling the soln. forms an elastic jelly. If air is excluded and stirring avoided and the heating is carried out in sealed bottles, the rate of dispergation at 150° is approx. that obtained at 128° (above). The dispergation rate as usual increases with increasing temp. At 180° complete dispergation is reached in 1.5 hrs. BaBr_2 solns. did not effect complete dispergation of cellulose. Only a portion entered dispersoidal soln. On the other hand, the fiber was broken down into particles which formed a flaky ppt. with fine-grained structure. Photomicrographs, ultraphotomicrographs and curves illustrate the article. VIII. Quantitative study on cellulose dispergation in concentrated aqueous solutions of calcium bromide and calcium chloride. P. P. VON VEIMARN AND S. OTSUKA. *Ibid* 47-60.—Cellulose is readily dispergated by satd. CaBr_2 solns. With 1 g. cellulose in 100 cc. of satd. CaBr_2 (satd. at 15° and allowed to remain in contact with cellulose for 3 days), complete dispergation takes place at 110° in 13 hrs., at 150° in 0.5 hr. When 3 g. cellulose are used, dispergation at 110° is incomplete after 20 hrs. but is complete at 150° in 1 hr. With 100 cc. CaBr_2 soln. satd. at 50°, 1 g. of cellulose was dispergated at 120° in 4 hrs. and at 150° in 20 mins.; 3 g. of cellulose were dispergated at 120° in 6.5 hrs. and at 150° in 0.5 hr.; 4 g. of cellulose were dispergated at 120° in 9 hrs. and at 150° in 1 hr. Ultraphotomicrographs show that the swollen cellulose fibers split into very fine fibrillae prior to dispersion. Dispergated systems normally form translucent jellies on cooling. With 100 cc. satd. CaCl_2 solns. at 150° in a sealed flask, 1 g. of cellulose was incompletely dispergated in 9.5 hrs. The partially dispersed material failed to gelatinize. The hot disperse system on pouring into H_2O forms unorganized agglomerated flakes. These micro-particles may be orientated in a single direction by exerting slight pressure on the cover glass of the microscopic slide. (Illustrated by ultraphotomicrographs). IX. The ability of thiocyanates and halides of alkaline-earth metals to produce dispergation of cellulose. P. P. VON VEIMARN. *Ibid* 63-7.—An interpretation of the preceding exptl. data. The capacity for dispergating cellulose by different salts is approx. in the following order:

Ca salts > Sr salts > Ba salts; cyanates > iodides > bromides > chlorides.
Dispergating capacity decreases

The difficulties of making definite observations are emphasized and v. V. points out that while the dispergation capacity is in the order: $\text{CaCl}_2 > \text{BaBr}_2 > \text{SrCl}_2 > \text{BaCl}_2$, none of these salts produces complete dispergation. X. Cellulose dispergation in aqueous sodium citrate and calcium chloride solutions of extremely low concentrations. P. P. VON VEIMARN AND H. HORI. *Ibid* 71-9.—Dispersoidal solns. of cellulose in hot concd. salt solns. capable of gelatinizing on cooling are termed "dispersoidal solns. of the 1st kind." Those which are very dil. solns. of cellulose in cold salt solns. are termed "dispersoidal solns. of the 2nd kind." A preliminary study of the latter has been made by v. V. and H. Detns. of the amts. of cellulose dispergated by dil. aq. solns. of Na citrate indicate that max. dispergation (15-17 mg. of cellulose per l.) is obtained by 0.025-0.05 millimolar Na citrate solns. This max. corresponds closely to the max. point on a curve drawn by plotting the concn. of Na citrate against the time (in days) required for complete clearing of the disperse system. A similar study with dil. CaCl_2 solns. indicated that the max. dispergation (12-13 mg. of cellulose per l.) occurred in 0.025 millimolar CaCl_2 solns.

Sodium hydroxide and cellulose. J. D'ANS AND A. JÄGER. *Cellulosechemie* 6,

LOUIS E. WISE

137-51(1925).—The work of recent investigators of the cellulose-NaOH relationship has been critically reviewed (cf. Dehnert and König, *C. A.* **19**, 1050; Heuser *et al.*, *C. A.* **19**, 1051, 2272; Karrer and Nishida, *C. A.* **19**, 1051; Liepatov, *C. A.* **19**, 2152, 3188; Vieweg, *C. A.* **19**, 1050; Rassow and Wadewitz, *C. A.* **18**, 1568) and their data have been recalculated so as to det. in each case the no. of g. of NaOH in 100 cc. of soln. (after the cellulose has reacted with NaOH) and the no. of mg. NaOH taken up per g. of cellulose. The various absorption curves, redrawn on this basis, show some similarities, but also some striking divergences. d'Ans and J., in studying NaOH-cellulose adsorption, used various grades of cotton, chem. pulp, and mercerized cellulose, and carefully controlled the temp. In general the absorption curves for chem. pulp were somewhat higher than those for cotton, and it was also shown that temp. had a marked effect on absorption, which was higher at 2° than at 23°. Absorption curves for these 2 temps. are fairly similar in shape, but not parallel. In each case they show a flattened portion between 16 and 24% NaOH, giving indication (but not proof) of compd. formation. The addn. of 5-10% NaCl or 5% Na₂CO₃ to the NaOH soln. does not influence the absorption of NaOH by cellulose at the lower concns., but enhances absorption above 10% NaOH. (This finding contradicts the work of Liepatov.) The soly. of cellulose in NaOH is of decided importance in a study of the alkali celluloses. While the solubilities of different samples of cellulose in NaOH were shown to be very different, soly. curves indicate that in all cases the *max soly. of the cellulose (at 23°) occurred at about 12% NaOH (vol. %)*. Past this point, the soly. rapidly decreased, usually falling to nearly 0 at 40% NaOH. The soly. of β -cellulose (the portion sol. in NaOH, but pptd. by AcOH) in NaOH decreased more rapidly than did that of the γ -cellulose (the portion sol. in alkali and not pptd. by AcOH, but pptd. by addn. of EtOH). The simplest explanation of the soly. curves is that the soly. of the alkali celluloses is decreased by addn. of an excess of NaOH, and that the soly. of "NaOH- β -cellulose" is lowered more rapidly than that of "NaOH- γ -cellulose." Swelling of cellulose probably runs parallel to the soly. of cellulose in alkali, with a max. swelling at 12% NaOH. Present exptl. data on swelling are meager and data to be published elsewhere are used in the present paper. Soly. expts. carried out at 2° gave results that were less certain than those obtained at 23°, the max. soly. of the cellulose being reached *below* 11% NaOH. In view of the above soly. data, a revision for the methods used in detg. β - and γ -cellulose is suggested. The detn. of soly. of cellulose in 10-12% NaOH at 0-2° and at 20-25° would probably give characteristic figures for each individual kind of cellulose. Using all available data on adsorption, soly., swelling, etc. (and admitting the gaps in the exptl. work), d'Ans and J. have studied the ternary system: cellulose-NaOH-(H₂O)₂, using the equilateral triangular method of representation. The 3 phases are NaOH soln. (contg. more or less cellulose in soln.), swollen cellulose (*i. e.*, alkali cellulose) and the gaseous phase. The system has 2 degrees of freedom, concn. of NaOH and temp. Cellulose (in this system) is assumed to be a chem. individual, although its entire behavior makes it apparent that even highly purified cotton cellulose is a mixt. of mols. of different sizes. The binary system: NaOH-H₂O has been previously studied. In the system: cellulose-NaOH, the assumption is made that cellulose forms 2 compds. with NaOH:-(C₆H₁₀O₅)₂-NaOH and (C₆H₁₀O₅)₃-NaOH. In the system: cellulose-H₂O, exptl. data regarding the amt. of H₂O taken up by cellulose are lacking, and the assumption is made that cellulose is capable of combining with 15% H₂O. Study of the ternary system includes tabulated data and curves based on the soly. of a sulfite pulp, and on the approx. compn. of swollen cellulose in 8, 12, 16, 24, 36 and 52.4% NaOH. (For detailed discussion and data the original must be consulted.) This method of investigation gives a means of studying changes in compn. of swollen alkali cellulose, when celluloses of different origin are used, and when temps. are varied. The diagrams probably give a clearer insight into the mercerization phenomenon than do any expts. hitherto recorded, and d'Ans and J. suggest that the method be adopted for the study of such systems as cellulose-cuprammonium hydroxide-H₂O; cellulose-HNO₃-H₂O, etc. The work of Vieweg (*C. A.* **19**, 1050) on the system NaOH-cellulose, to which EtOH has been added, was repeated since V.'s results are out of harmony with the cellulose-NaOH absorption curves. The new results differ from those of V. While a simple stoichiometric relationship does not exist between cellulose and NaOH, when EtOH is present in soln., d'Ans and J. show that in the presence of 10% EtOH, the absorption curve still shows a flat portion at 16-24% NaOH, and even when larger amts. of alc. are added, the rate of absorption of alkali is decreased in this region. With increasing amts. of alc. added, the amt. of NaOH taken up by the cellulose (at any NaOH concn.) increases. d'Ans and J. also studied the alkali absorption of various other chem. pulps and viscose. The data are similar to those found with cotton. Soly. curves indicate that at 2°, the max. soly.

takes place at a concn. of 9–11% NaOH; at 23°, the max. lies at 12% NaOH. With viscose, at 2°, an "unlimited swelling" (complete soln.) takes place at the point of max. soly. Each set of soly. curves (*i. e.*, curves indicating the soly. of a particular kind of cellulose at 2° and also at 23°) shows a point of intersection, indicating a definite alkali concn. at which the soly. of cellulose is the same at either temp. The more sol. the original cellulose the higher the NaOH concn. at which this point is reached. (*E. g.*, viscose shows identical soly. in 26% NaOH (by vol.) at 2°, as it does at 23°. With a bleached pulp, this point was reached with 21% NaOH.) LOUIS E. WISE

Nature of solutions of cellulose in cuprammonium hydroxide. S. M. NEALE. *J. Textile Inst.* 16, T363–9 (1925).—Based on a consideration of the properties of cuprammonium cellulose solns., the hypothesis is put forward that these solns. belong to the class of colloidal electrolytes, typified by soap solns. According to this theory the strong base $\text{Cu}(\text{NH}_3)_4(\text{OH})_2$ forms with cellulose, which thus behaves as a weak acid, a sol. basic salt of which the cation is "crystalloidal" and the anion "colloidal." It appears that each cellulose hexose unit ($\text{C}_6\text{H}_{10}\text{O}_6$) is associated with one atom of Cu, and thus the anionic micelle consisting of a large no. (*n*) of condensed hexose groups and carrying *n* negative charges, is, together with *n* hydroxyl anions, equiv. to *n* bivalent cuprammonium cations. $(\text{C}_6\text{H}_{10}\text{O}_6)_n + n\text{Cu}(\text{NH}_3)_4(\text{OH})_2 \longrightarrow (\text{Cu}(\text{NH}_3)_4)_n \cdot (\text{C}_6\text{H}_9\text{O}_6)_n \cdot (\text{OH})_n + n\text{H}_2\text{O}$, the salt being highly ionized into $n\text{Cu}(\text{NH}_3)_4^{++}$, *n*OH and $(\text{C}_6\text{H}_9\text{O}_6)_n^-$. Cellulose neutralizes the cuprammonium to the extent of using completely the hydroxyl arising from the first dissociation of the substance. Further action is presumably inhibited on account of the weaker dissociation of the base with respect to its second hydroxyl, and by the impossibility of the existence of the sol. cellulose complex in any but a highly alk. medium. This hypothesis accounts in a satisfactory manner for the properties of the solns. The foregoing hypothesis is supported by the results of expts. on cuprammonium cellulose solns. in the following lines: *e. m. f.* measurements, electrolysis of the solns., heats of soln. of sugars, and pptn. of a solid contg. cuprammonium and cellulose. L. W. RIGGS

Time factor and yield value of cellulose esters. S. F. SHEPPARD, E. K. CARVER AND S. S. SWEET. *Ind. Eng. Chem.* 18, 76–7 (1926).—"Films of cellulose esters are imperfectly elastic and flow slightly even under very small loads. The yield points, as obtained by ordinary strength testing machines, depend largely on the speed at which the machine is run." LOUIS E. WISE

The action of ammonia on cotton cellulose. G. BERNARDY. *Z. angew. Chem.* 38, 1195–7 (1925).—Purified cellulose when treated at 200° and 40 atm. for 48 hrs. with 22% aq. NH_3 left a brown powder contg. 20% N. T. S. CARSWELL

The chemistry of the sulfite pulp process. ERIK HÄGGLUND. *Svensk Kem. Tids.* 37, 116–24 (1925). (In German).—Wood lignin is chemically combined with a carbohydrate. The rate of fixing the SO_2 is rapid at the beginning of the process but slows down very much through the formation of inhibiting substances. The ash in the residue runs parallel with the S. The sugar in the liquor runs parallel with the soln. of ligninsulfonic acid. The discoloration of the pulp is discussed. With the increase in ligninsulfonic acid the H_2SO_3 decreases. The bases present combine with both acids but the partition of the bases between them is not clear. At the end of the process there is only a small amt. of free ligninsulfonic acid present. Cf. C. A. 20, 284. A. R. ROSE

Solubility of lignin in phenols. ARMIN HILLMER. *Cellulosechemie* 6, 189–87 (1925).—Lignin as it occurs in the original plant has never been isolated; "primary lignin derivs." include "acid-lignin," "alkali-lignin," ligninsulfonic acid, "lignin chloride" and "phenol-lignin." H. has investigated the latter and has systematically detd. the soly. of encrusting materials of wood in various phenols. Wood flour (species not given) and "acid-lignin" (isolated by means of HCl) were studied. The soly. in the isolated phenol of acid lignin was always similar to that of the original wood lignin. The soly., however, involves a chem. reaction since the "phenol-lignins" are quite different in their properties from the "acid-lignin" or lignin of the original wood. The mechanism of the condensation of lignin with phenol is discussed at some length. In the soly. tests, 1 part of lignin was treated with 50 parts of the molten phenol. If the material dissolved rapidly at a temp. approximating the [m. p. plus $\frac{1}{3}$ (b. p. minus the m. p. of the phenol)] the lignin solvent was termed *excellent*. If the material dissolved completely above this temp., the solvent was termed *good*. If the solvent was heated to its b. p. before any soln. of lignin took place, the soly. was termed *slight*, or *very slight* as the case might be. If no discoloration of the solvent occurred at its b. p. the lignin was considered *insol.* In certain instances the soly. of the lignin was markedly increased by the addition of catalysts to the phenol, *e. g.*, in PhOH lignin is insol., but

this becomes an excellent solvent in the presence of HCl, Br, H_3PO_4 , $HClO_4$, and H_2SO_4 . The solvent powers of a large no. of phenols are given on the above classification. In general, phenolic delignification of wood, or soln. of isolated lignin is best effected by using a phenol with two OH groups, a hydroxybenzoic acid, or a phenol contg. a NO_2 , Cl, Br, or CHO group *m*, or *p* to the OH. The solvent action on lignin of a large number of non-phenolic substances was also studied. These included esters, amines, aliphatic acids, phenyl fatty acids, aralkyl alcohols and aldehydes, aromatic hydrocarbons and their substitution products, aromatic acids and aldehydes, sulfonic acids and acid chlorides, hydroaromatic compds., naphthalene derivs. and heterocyclic compds. "Phenol-lignins" were prepd. and purified by the following general method: the melted anhydrous phenol is treated with the lignified tissue or with "acid lignin" (depending upon whether "primary" or "secondary" phenol lignin is desired). If necessary 1% of a mineral acid or 0.2% I is added as catalyst. The mixt. is heated in a bath (temp. depending on the nature of the phenol used) until soln. is nearly complete (but before the cellulose is greatly attacked). The soln. is cooled (care being taken to avoid solidification) and filtered. The excess phenol is removed from the filtrate by distn. *in vacuo* and the viscous residue poured into anhydrous Et_2O . The ppt. is filtered off, washed with abs. Et_2O (with exclusion of moisture), and dried. The powdered "phenol lignin" may then be further purified by soln. and reprecipn. from Me_2CO , or by extn. with anhydrous Et_2O or $CHCl_3$. The phenol lignins are amorphous substances varying in color from purple to brown-black, sol. in glacial AcOH, MeOH, $EtOH$, AmOH, AcOEt, Me_2CO , C_6H_6N , quinoline, $PhNH_2$, phenols and in aq. NaOH. They are insol. in H_2O , Et_2O , $CHCl_3$, CCl_4 , CS_2 , NH_4OH , Na_2CO_3 solns. and aq. mineral acids, petroleum solvents, $ClCH:CCl_2$, C_6H_6 , PhMe and in turpentine and in rosin. The following lignin derivs. were isolated: "Primary phenol lignin" (obtained by the action of PhOH on wood flour) contg. 0.49% ash, 64.42% C, 5.96% H, and contg. no AcO groups; "secondary phenol lignin" (obtained by the action of PhOH on acid lignin) contg. 0.74% ash, 71.63% C, 5.28% H, and 12.15% MeO; primary creosote lignin contg. 0.70% ash, 66.35% C, 5.84% H, and 12.17% MeO (free from halogens) primary *p*-chlorophenol lignin, analytical data fluctuating widely with slight variations in method of prepn. (3.48-7.55% Cl, 64.67-57.96% C, 5.72-5.06% H); primary *p*-chloro-*m*-cresol lignin, contg. 0.73% ash, 58.48% C, 5.27% H; primary *o*-nitrophenol lignin, 2.15% N, 0.86% ash, 64.0% C, 4.72% H, 9.86% MeO. (There is no exptl. evidence that these "phenol-lignins" are homogeneous.)

Alcoholate digestion of wood (HOLMBERG, RUNIUS) 11D. Organophile colloids (WHITBY) 2.

HOVER, FRITZ: *Die Pappenfabrikation*. Prakt. Handbuch. Berlin: M. Krayn 316 pp. R. M. 18, bound R. M. 20.

Bleaching cellulose. KÖLN-ROTTWEIL AKT.-GES. and J. OPFERMANN. Brit 234,454, May 22, 1924. Bleaching with Na or Ca hypochlorites is carried out in the presence of a small quantity of NaOH, alk. earth hydroxide or $Mg(OH)_2$ which may be about 1% the wt. of the cellulose.

Cellulose solutions. A. CLASSEN. U. S. 1,570,553, Jan. 19. The soln. of cellulose in HCl at moderate temps. is facilitated by the presence of metallic catalysts which are not readily attacked by HCl, *e. g.*, metals of the Pt group, W, ferro-W, ferro-V, silicides, Borchers metal (in which Ni may be replaced by Co, W by Mo and Ag by Cu) or Cu (the latter, however, being less suitable). Use of pressure facilitates the reaction also.

Alkali celluloses. F. VAN WEYENBERGH. U. S. 1,569,692, Jan. 12. In producing alkali celluloses contg. not less than 30% by wt. of caustic alkali and not more than 35% by wt. H_2O , the cellulose is steeped in a soln. contg. more than 55% by wt. of caustic alkali at a temp. of at least about 40° (but not high enough detrimentally to affect the cellulose) and the excess caustic alkali soln. is then removed while the material is still at an elevated temp.

Destructive distillation of sulfate cellulose waste lye. E. L. RINMAN. Swed. 59,923, Nov. 24, 1925. The distn. is discontinued when the more valuable org. substances have been evapd. after which the residue is discharged and burned to complete oxidation or carbonization of all the org. matter.

Cellulose acetate composition. H. BUCHHOLZ. U. S. 1,568,955, Jan. 12. A compn. for making elec. insulators or other molded articles comprises cellulose acetate, powd.-glass, bone meal or glue and magnesite.

Dyeing cellulose acetate. BRITISH DYESTUFFS CORPORATION, LTD., J. BADDILEY and H. BROWNING. Brit. 233,813, Feb. 27, 1924. Cellulose acetate goods are dyed from a hyposulfite vat without hydrolysis by means of quinone arylides of the benzene or naphthalene series or thiazines, azines, or oxazines derived from them. Numerous examples are given.

Wood pulp. C. J. STERNKOPF. Brit. 234,120, May 15, 1924. In the mech. production of wood pulp, the wood is softened by treatment with heated H_2O in the grinding app., before grinding.

Refining sulfite spirit. UDDEHOLMS AKTIEBOLAG. Swed. 59,818, Nov. 10, 1925. Pure alc., methanol and acetaldehyde are obtained from raw or rectified sulfite spirit by treating it with an acid or an acid salt with a subsequent sepn. of the components in known ways.

Non-inflammable cellulose ester and ether compositions. W. G. LINDSAY. Brit. 233,874, May 5, 1924. Cellulose esters or ethers or similar substances are mixed with an aromatic phosphoric ester and with substances such as Al phosphate, hydrated AlF_3 , Ca phosphate, Ca tartrate, Ca citrate, or Mg di-H ortho-antimonate.

Paper pulp from rice hulls. R. MORGENIER. U. S. 1,570,389, Jan. 19. Rice hulls are cooked in a 10° B \acute{e} . soln. of NaOH for about 2 hrs., sepd. from the soln. and beaten to a pulp.

Rubberized paper. RUBBER LATEX RESEARCH CORPORATION. Brit. 234,245, April 7, 1924. Paper, pulp board and pulp articles are treated with a soln. of latex stabilized with NH_3 or other alkali and then dried to convert the latex solids into a dried irreversible gel. To facilitate impregnation, paper may be moistened with H_2O , alc., ether or other volatile liquids. The product may be vulcanized or may be rendered tacky and faced with finely divided china clay or similar materials.

Rendering paper transparent. C. E. SWERT. U. S. 1,570,098, Jan. 19. In impregnating paper with a resinous compn. or similar substances to render it transparent, it is alternately heated and cooled to facilitate penetration and solidification of the impregnating substance.

Machine for the manufacture of paper board. O. V. BERGLUND. Swed. 59,924, Nov. 24, 1925.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Report of the Chief of the Bureau of Ordnance, U. S. N. for fiscal year 1925. C. C. BLOCH. Wash. Govt. Printing Office, *Phamphlet*, 13 pages.—This report for the year ending June 30, 1925 covers the various activities of the Bureau. Under casualties is brief mention of a *dust explosion* occurring Aug. 21, 1924, at the Naval Gun Factory, during the mixing of chemicals for a pyrotechnic compn.; the accidental *ignition of powder on the U. S. S. Trenton*, Oct. 20, 1924, while the powder was being brought up to the left gun of the forward mount, the court of inquiry being of the opinion that the accident was caused by the breaking of a powder bag and the consequent grinding up of powder in the mechanism of the hoist but it obtained negative results only in attempts to reproduce this effect; an explosion Jan. 7, 1925 at Hingham, Mass. in the *breakdown machine* while breaking down 3-in. projectiles; and on Apr. 24, 1925 at Indianhead, Md. an *empty tank*, which had been used in the recovery of solvents, in the manuf. of smokeless powder was destroyed by an explosion, due, it is surmised, to nitrocellulose in very fine granular form, having been carried over with the solvent and lodged in the tank, where it exploded spontaneously.

CHARLES E. MUNROE

Safety considerations as regards military explosives. G. PANDELE. *Chem. Age* (London) 13, 392(1925).—Wood-cellulose cotton wool is more readily nitrated than cotton cellulose in the same form and the resulting fulmicottons contain less N, are more sol. and retain the mixed acids to a greater extent. They can be made inert in much shorter time than the cotton nitrocelluloses and are far more stable. They dissolve more readily in Et_2O , requiring but about $1/2$ the quantity of ordinary gun-cotton.

CHARLES E. MUNROE

Gaseous explosions. II. Homogeneous and heterogeneous reactions defined and classified. G. G. BROWN. *Ind. Eng. Chem.* 17, 1229-32(1925); cf. C. A. 19, 1630.—Gaseous explosions are defined and classified under (a) homogeneous reactions wholly confined within a single gas phase and (b) heterogeneous occurring at the interface between 2 phases. Under (a) is classed (1) continuously homogeneous reactions, (2) progressive homogeneous reactions and (3) hetero-homogeneous or compd. pro-

gressive homogeneous reactions, and under (b) is classed (4) gas-gas, (5) gas-liquid and (6) gas-solid heterogeneous reactions. Surface catalysis of a gaseous reaction makes the reaction heterogeneous. This is of particular importance in internal-combustion engines. Mixed catalysts, such as those of Midgley and Boyd, affect homogeneous and heterogeneous reactions.

CHARLES E. MUNROE

An apparatus for studying gases of explosives detonated under confinement. J. H. CRAWSHAW AND G. W. JONES. *Eng. Mining J.-Press.* 120, 965-7(1925).—Beginning with the researches of Noble and Abel, some 50 years ago, repeated investigations have been made of the gaseous products from the detonation of explosives, but all have been made in vessels of limited capacity with low charging ds. and the samples for analysis were taken only after the gaseous products had slowly cooled under high pressures, during which reactions between the original components of the mixt. had taken place, giving rise to a different end product. Efforts have been made at the Bureau of Mines to ascertain directly the compn. of the products when the explosives were fired in mines but numerous difficulties were encountered in taking samples. C. and J. have sought to devise an app. in which explosives may be fired under mining conditions requiring (1) the use of fairly large charge; (2) a fairly rapid rate of cooling by conduction, radiation and expansion, because under mining conditions the explosive is surrounded by large masses of material and the detonation products are rapidly released into large vols. of air, (3) a confinement representative of mining conditions; and (4) detonation in contact with various minerals. The app., in which charges of 150 g., and larger, may be fired, is described in detail, with sketch and an illustrative typical example of a test given.

CHARLES E. MUNROE

Liquid-oxygen explosives. ERNEST FYLEMAN. *Proc. Fourth Intern. Congress of Refrigeration* 2, 1107-24(1924).—Brief outline of their theory and development, with a description of present day practice.

A. PAPINEAU-COUTURE

Explosion of ether and oxygen during a surgical operation. ANON. *Chem. Age* (London) 13, 399(1925).—In an operation for a fractured jaw, at East Ham on Oct. 8, 1925, Et_2O and O_2 were employed as the anesthetic, the patient's teeth being kept dry with warm air from a dental syringe. On the third application of warm air a violent explosion occurred in the patient's throat causing an acute and fatal hemorrhage. There was no naked light within 6 ft. of the patient.

CHARLES E. MUNROE

Inflammability of ether vapor. A. TAYLOR. *Chem. Age* (London) 13, 449(1925).—Comment on accident at East Ham (preceding abstract). The menace from naked flames in the presence of Et_2O vapors is pointed out. Such vapors have been known to be ignited by a flame 10 ft. distant.

CHARLES E. MUNROE

Warning against the customary process for preparing cooling baths from inflammable compounds with the aid of liquid air. WILHELM BILTZ. *Chem.-Ztg.* 49, 1001(1925).— CS_2 and liquid air mixt. caused a violent explosion at the Technische Hochschule, Hannover, although the method used was that commonly employed and recognized as correct. No satisfactory cause for the accident was found; this warning is issued accordingly.

W. C. EDAUGH

2,4,6-Trinitrobenzoic acid from the photochemical decomposition of 2,4,6-trinitrotoluene. KRANZ AND TUREK. *Chem. Age* (London) 13, 392(1925).—The Luttgen process has proved perfectly satisfactory for its prepn. when the crude product is purified with Na_2CO_3 instead of NaOH . All the trinitrobenzoates prepd. have proved to be cryst. substances with the exception of the Bi, Sn and Al salts, which are amorphous and have an indefinite constitution. All explode or detonate, either on shock or by heat, except the Hg compds. The presence of min. quantities of the metallic trinitrobenzoates considerably increases the explosiveness of TNT. In the presence of moisture trinitrobenzoic acid attacks Pb, Cu and Fe very readily, whether air be present or not, and the resulting salts explode on heating or impact. As com. trinitrotoluenes may contain trinitrobenzoic acid, the possibility of such salts being formed should always be guarded against in circumstances where there is any likelihood of their occurrence.

CHARLES E. MUNROE

Flame-proof electrical apparatus for use in coal mines. First report.—Flange protection. I. C. F. STATHAM AND R. V. WHEELER. Mines Department, *Paper No. 3, Safety in Mines Research Board*, 50 pp.—Factors governing the propagation of flame in fire damp within spherical vessels, both totally closed and with gaps of various widths left between flanges of different breadths at joints between 2 hemispheres, is investigated. In totally enclosed vessels, the percent of methane is detd. for max. pressure, and the influence of vol., asymmetrical ignition, turbulence and intensity of source of ignition is investigated. With vented vessels the influence of vol., breadth of flange, width of gap, and character of gap on the pressure is first investigated. The

ability of the gaps to prevent the passage of flames sufficient to ignite explosive mixts. of fire damp and air surrounding the vessels is considered and in this connection the influence of vol. of vessel, breadth of flange, position of ignition and compn. of mixt is investigated. The investigation of the influence of the intensity of the source of ignition is as yet unfinished. Conclusion With proper design a gap can be left for the release of pressure through the flanges of the enclosures of elec. mining app. inasmuch as a gap at such flanges of as much as $\frac{3}{64}$ in. does not, so far as our knowledge goes at present, enable the flame of the most explosive mixt. of fire damp and air to pass through it, but a breadth of less than 1 in. for flanges should not be used. Also, probably the most convenient application of the principle of flange protection will be in the use of "rough" machined instead of "finished" flanges or special bolts to allow a slight opening between flange surfaces when pressure is developed in the casing. L. C. LLSLEY

Accidents caused by acetylene apparatus. SCHOLTE. *Revue de la soudure autogène* (Oct., 1925); *Genie civil* 87, 516(1925).—Most accidents are caused by the presence of air in the apparatus and by the ignition of explosive mixtures by too elevated temperatures. JACK J. HINMAN, JR.

Physical condensation of dyes on fiber. R. HALLER AND A. RUPERTI. *Cellulosechemie* 6, 189-95(1925).—Chardonnet rayon when treated with β -naphthol followed by diazotized α - $\text{C}_7\text{H}_7\text{NH}_2$ showed a homogeneous microscopic appearance. On boiling with H_2O , the color tone changed and on heating under 6 atm., the dye particles decreased in no. and increased in size and appeared to migrate from the inner part of the fiber to the surface, on which they were finally deposited in the form of relatively large crystals, that adhered poorly and could be removed by pressing or washing. Cross sections of the fiber show that the inner portions are colorless. Many dyes manifest this same behavior and the phenomenon of surface accumulation and condensation appears to be general, when the fiber is heated under steam pressure. The pigment PbCrO_4 pptd. in the rayon fiber behaves differently. When heated with H_2O under 4 atm., the pigment was fully condensed, but a cross section of the fiber showed that it was uniformly distributed throughout the cell wall and not concd. at the surface. With cotton fiber dyed with various vat dyes, substantive dyes and dyes fixed by mordants, the growth of dye particles is at the outer surface as well as on the inner surface (bounding the lumen). The accumulation of dye particles within the lumen after the crystals migrating to the outer surface have been mechanically removed is clearly illustrated by numerous photomicrographs. Factors influencing the phys. condensation of dyes are the concn. of the dye, the pressure used in cooking, and the time of cooking.

In most cases simple heating in a boiling dye bath was insufficient but often protracted heating under slightly increased pressure proved sufficient to cause condensation of the dye. Dry heat never caused growth of crystals on fiber surfaces, although in individual cases, like Para-red, the dye sublimed out of the cell wall. Among the dyes which crystd. readily on the outer and inner surfaces of the fiber were indigo and thioindigo. Indanthrene Red 5GK was condensed on cotton by heating at 0.1-0.3 atm. excess pressure for 2 hrs. and after a short period of heating at 6 atm. was obtained on the surface and lumen in the form of long needles. Indanthrene Brilliant Violet RK condensed much more slowly and particles sepd. at the surface only after protracted heating. Indanthrene Blue RS showed no accumulation of cryst. surface particles, even after long heating under pressure. In the latter case the dyed fiber appeared practically uniform under the microscope and the only indication of condensation was the change in color tone. Ultramicroscopic examn. after steaming substantiated this evidence of increase of size of particles. A no. of dyes showed similar changes in color tone, which apparently characterizes condensation of the dye. Among the substantive dyes, Diamine Blue 3R, Congo Red and Congo Corinth showed unmistakable condensation. Trypan Red and Carbazole Yellow, however, remained unchanged. Cotton samples which had been mordanted with basic Al acetate, when uniformly dyed with Alizarin Red and steamed under pressure, showed migration of the dye to the outer and inner surfaces with the formation of the usual non-adherent particles. When similarly mordanted cotton was treated with Turkey red oil prior to dyeing with Alizarin Red, this migration and surface condensation was much less marked, showing that the oil served as a protective colloid inhibiting the growth of dye particles. As with Chardonnet silk, cotton dyed with PbCrO_4 evidenced no sign of migration or surface condensation. The pigment is deposited in the form of micro-crystals throughout the entire cell wall. H. and R. discuss the practical significance of their findings in connection with comm. printing and dyeing. LOUIS E. WISE

The dyeing of silk white effects on woollens and worsteds. ALAN A. CLAFLIN. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 21-2; *Am. Dyestuff Rept.* 15, 23-4.

Life of tent fabrics. J. A. HUNTER. *Textile World* 69, 309-11, 315(1926).—Expts. by the British Government upon cotton and linen tent fabrics indicate that the heavy tent fabrics are much less affected by the deteriorating influence of sunlight than are the light and much-exposed fabrics used in airplane and airship construction. Micro-organisms are the chief enemies of tent fabrics and their effects are most devastating in hot, damp climates. Chem. action is also a factor and in certain fireproofed fabrics,

it is the dominant cause of deterioration. The deteriorating action of sunlight, possibly caused by ozone formation, can be diminished by the proper use of pigments which are impervious to light, such as PbCrO_4 . The tannates, tungstates and sulfides frequently used in fireproofing, accelerate the deterioration. Waterproofing frequently, but not always, has a beneficial action, depending upon the process and materials used and the climatic conditions of exposure. Tables are given showing the tensile strength of waterproofed fabrics and the deterioration under exposure in various climates. Terra cotta-dyed cuprammonium-treated linen is regarded as the best tenting fabric, followed by cutch-dyed cotton. The latter has the greatest water-tightness.

CHAS. E. MULLIN

The pectin content of flax fiber. WM. HONNEYMAN. *J. Textile Inst.* **16**, T370-4 (1925).—"The ultimate fiber appears to be composed of a central column of pure cellulose, surrounded by layers of compound celluloses or hemicelluloses, contg. progressively less cellulose up to the outside layer (the middle lamella) where most of the pectin occurs. From a practical standpoint these suggestions offer an explanation of the difficulty of bleaching flax. In fully bleached material the fiber bundles are not present but have been resolved into their ultimate fibers. It is the difficulty of removing the pectin associated with the middle lamella which necessitates the protracted process used in order to resolve the bundles. If this pectin material is not removed, cloth made from the fiber will be discolored by alk. washing or by long storage." L. W. RIGGS

Method for evaluation of diastatic compounds. W. W. CHASE AND E. R. DONALDSON. *Textile Colorist* **47**, 781-2(1925).—C. and D. recommend a modification of Wohlgemuth's method of evaluating diastatic products for textile use. Sat. clean, dry, white cotton sheeting with a 1% soln. of cornstarch, mangle, dry and cut into swatches of 5 g. each. Add varying amts. of an aq. 1% diastatic soln. and H_2O to 150-cc. beakers to give a total vol. of 100 cc. Sat. each 5 g. swatch with one of these solns., lightly squeeze to a total wt. of 10 g., roll loosely and hold at 49° for 30 min. Then unroll and test with a drop of 0.1 *N* I soln. for a violet end point, which indicates complete solubilization of the starch. C. E. M.

Carpet beetles. A. P. SACHS. *Textile Colorist* **47**, 783(1925).—Larvex was effective against these insects in lab. expts. CHAS. E. MULLIN

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE and H. FRITZSCHE. *Brit.* **234,319**, July 22, 1924. The process of *Brit.* **219,653** (*C. A.* **19**, 736) is modified by substituting wholly or in part (for the aminomonoazo dyes used as diazo components) aminodisazo dyes. Dyes are formed by (a) coupling the urea of a 1-aminoaryl-5-pyrazolone with 2 mol. proportions of the same or different diazo-disazo compds. or 1 mol. of such compd. and 1 mol. of a diazoazo compd.; or, (b) by reacting with phosgene on the trisazo dyes made by coupling a diazo-disazo compd. with a 1-aminoaryl-5-pyrazolone. The dyes produce brown shades on cotton dischargeable to a pure white. Various examples are given.

Dyes. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING. *Brit.* **234,173**, Feb. 20, 1924. Dibenzanthrone dyes which dye cotton from a vat in violet, blue, gray-blue and similar shades are made by alkali fusion of hydroxybenzanthrones contg. no substituents or only halogen in the peri-positions of the naphthalene nuclei and alkylating the resulting dibenzanthrones. Among the various starting materials which can be used is *p*-methoxyphenyl α -naphthyl ketone, which is obtained by condensing α -naphthoyl chloride with anisole in the presence of AlCl_3 . 3- and 6-Methoxy-1-benzoylnaphthalenes are obtained, resp., from 3- and 6-hydroxy-1-naphthoic acids by methylating with Me_2SO , converting to the acid chlorides with thionyl chloride, and condensing with C_6H_6 in the presence of AlCl_3 .

Dyes. J. THOMAS, L. J. HOOLEY AND SCOTTISH DYES, LTD. Brit. 234,533, Jan. 26, 1924. Hydroxy- and chlorohydroxyanthraquinones are produced by condensing phthalic anhydride with *o*-chlorophenol or a chloro deriv. such as 2,4-dichlorophenol, preferably in H_2SO_4 contg. H_3BO_3 . NH_3 soln. may be used for sepg. the resulting mixts. Examples are given of dyes giving red shades on wool which become bluer on chroming. Cellulose acetate is dyed by suspensions of certain of these derivs. The NH_3 -insol. portion dyes yellow and the alkali-sol. portion red shades.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 234,086, May 13, 1924. 5- or 8-Amino-2,1-anthraquinoneacridone is condensed with a 1,3,5-triazine deriv. halogenated in the nucleus and may be further condensed with other compds. The products obtained dye cotton red-violet to Bordeaux shades from a hyposulfite vat.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 234,681, July 17, 1924. Production of an indigo-blue dye by sulfurizing the leuco-indophenol from carbazole and nitrophenol in the presence of benzidine (as described in Brit. 199,360; cf. C. A. 18, 333) is effected in the presence also of a substance such as NaCl , Na_2SO_4 or Na_2CO_3 which prevents sintering of the mass during the reaction.

Dyes. FARBENFABRIKEN VORM. F. BAYER & Co. Brit. 234,569, March 13, 1924. Triarylmethane dyes are prep'd. by condensing an alkylated diaminobenzohydrol with 1-naphthol-2-carboxylic-7-sulfonic acid or with 1-naphthol-2-carboxylic-4,7-disulfonic acid and oxidizing the resulting leuco compd. Tetramethyl- and tetraethyl-diaminobenzohydrol produce dyes giving reddish blue and greener dyeings, resp.

Perylene vat dyes. A. ZINKE and H. SHOEPPER. U. S. 1,569,111, Jan. 12. By the treatment of perylenequinone with Cl a product is formed which gives a more brilliant color on cotton than the corresponding Br deriv.

Thioindigoid dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 233,831, June 12, 1923. A naphthioindoxyl or a nuclear halogen substitution product is condensed with the usual indigoid dye components such as isatins, thioisatins, acenaphthenequinone, naphthoquinones or their anilides or halides. The products may be halogenated and dye cotton from the vat in Bordeaux, brown, blue, violet and other shades. Numerous examples are given. Cf. C. A. 19, 2135.

Sulfuretted dyes. AKT.-GES. FÜR ANILIN FABRIKATION. Brit. 234,470, May 23, 1924. Brown S dyes are made by heating 2-methyl-3-amino-6-hydroxyphenazine with alkali polysulfide with or without metal compds., such as CuSO_4 , to temps. above 180° (in some cases $235\text{--}240^\circ$).

Dye intermediate. BRITISH ALIZARINE CO., LTD., J. ANDERSON AND W. H. DAWSON. Brit. 234,263, May 6, 1924. Leuco-1,4,5-trihydroxyanthraquinone is made by reduction of the trihydroxy compd. by alk. hyposulfite. NaOH and Na hyposulfite may be used for the reduction and the leuco compd. ppt'd. from the reduction mixt. by pouring into dil. H_2SO_4 , filtered, washed and dried.

Dyeing and tinting composition. A. DAVID. U. S. 1,569,915, Jan. 19. A compn. for use with H_2O in dyeing or tinting fabrics or other materials comprises soap, H_2O , glycerol and dye.

Dyeing warp in rope or chain form. H. M. CHASE and G. W. ROBERTSON. U. S. 1,568,959, Jan. 12. Warp in rope or chain form is boiled out, dipped in a vat dye, oxidized, re-dipped in the same dye, again oxidized, washed and dried.

Apparatus for dyeing "raw stock." J. H. THOMPSON. U. S. 1,569,647, Jan. 12. Washing, dyeing and fulling fabrics in rope form. E. MUNDORF. Brit. 234,472, May 20, 1924. Mech. features.

Mercerizing and similar treatments. L. LILIENTELD. Brit. 234,847, May 30, 1924. A silky gloss, brilliance and elastic feel are given to woven and spun vegetable material by treatment in the presence of alkalies with an inorg. ester of a monohydric alc., and stretching. Patterns may be produced by preliminary printing with reserve materials. Numerous examples are given.

Apparatus for mercerizing yarn. NIEDERLAHNSTEINER MASCHINENFABRIK GES. Brit. 234,443, May 21, 1924. Details of tensioning devices are specified.

Printing textile materials. FARBWERKE VORM. L. DURAND HUGUENIN & Co. ANON. Brit. 234,829, March 9, 1923. White or colored effects are produced on fabrics by padding with an ester of a leuco vat dye (as described in Brit. 186,057; C. A. 17, 343) together with an oxidizing agent effective only in an acid medium, printing with a reducing agent (other than a hyposulfite prepn.) and developing the unprinted parts by passage through acid. Na_2SO_3 and $\text{Na}_2\text{S}_2\text{O}_3$ may be used as reducing agents. Dyes other than vat dyes, capable of withstanding reducing agents, are added to the reducing agents to produce colored reserve effects.

Apparatus for drying textile materials. H. HAAS. Brit. 234,444, May 23, 1924.

drying time of the resultant oil films observed. Microscopic examn. showed a pronounced difference in the av. particle size of the two samples, but their soln. rates in the oil and the drying tests showed no significant differences. Results are plotted and tabulated.

F. A. WERTZ

Some constituents of French and American rosins. E. KNECHT AND E. HIBBERT. *J. Soc. Dyers Colourists* **41**, 329-33(1925); cf. *C. A.* **13**, 2290; **18**, 759.—This paper gives an abridged account of the work. The term abietic acids has been adopted in place of pimaric to designate the acids having the compn. $C_{20}H_{30}O_2$ and obtained from French or American rosins. The m. p. and rotation of the abietic acids and their salts are studied, also the formation and properties of the nitrosites of the *l*- and *d*-acids. Bromination of abietic acids yields the tribromo deriv. Vesterberg's *d*-pimaric acid was studied. Analogs of Vesterberg's *l* pimaric and *d*-pimaric acids were obtained from Pinion pine pitch (American)

L. W. RIGGS

The detection of rosin. HANS WOLFF. *Farben-Ztg.* **31**, 515(1925).—Further expts. (cf. *C. A.* **19**, 3602) on the detection of rosin in linseed oils by the Storch-Morawski test have revealed some oils extd. from paint pastes which gave suspicious color reactions for rosin even though the same oils before grinding with the pigments gave negative reactions. This was particularly the case with oils ground with pigments contg. larger amts. of Fe_2O_3 . Comparative color tests with oils contg. a known rosin content of 0.5 to 1% are recommended.

F. A. WERTZ

Rosin esters. HANS BRENDL. *Farben-Ztg.* **31**, 576-8(1925).—A brief review of the natural resin substitutes, and of patented and published methods for producing rosin-glycerol esters, with a description and sketch of a com. app. for autoclave esterification.

Colored cellulose acetate varnishes. CHEMISCHE FABRIK GRIESHEIM-ELEKTRON. Brit. 233,891, May 19, 1924 Varnishes are prepd. by shaking together solns. of a cellulose ester in org. solvents with aq. pastes of inorg. pigments, H_2O -insol. azo or vat dyes or color lakes prepd. from sol. dyes. Solns. of rubber or of sol. dyes also may be added.

Coumarone resin. C. ELLIS. U. S. 1,570,584, Jan. 19. Coumarone resin contg. acid substances is treated with a basic neutralizing agent such as soda or $Ca(OH)_2$ in the absence of sufficient H_2O to dissolve the basic material, and heated to above the m. p. of the resin.

Resin substitute produced by Friedel-Crafts reaction. F. FREUND and H. JORDAN. U. S. 1,570,469, Jan. 19. $C_{10}H_8$, xylene, phenolic compds. from low-temp. tar or other aromatic compds. of similar reactivity with halogen compds. according to Friedel and Craft's reaction are treated with halogen compds. such as naphthalene tetrachloride or acetylene tetrachloride in the presence of about 0.1-10% of fuller's earth which serves to catalyze the reaction.

Linseed oil substitute. J. HOROWITZ. U. S. 1,570,252, Jan. 19. A mixt. adapted for use as a vehicle in paints comprises crude rubber 25, kerosene or other solvent 75, rosin 100, PCl_3 4 parts and sufficient NaOH to render the mixt. alk.

Apparatus for heating and thickening linseed oil and similar oils. G. H. LENART. Brit. 233,948, Aug. 21, 1924.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The adoption of uniform testing methods for the fatty oil industry. ANON. *Farbe und Lack* 1925, 583-4.—General methods for sampling, detn. of total fatty acids, unsapon. matter, impurities, etc., presented for discussion by the Fat Analysis Committee, are given. F. A. WERTZ

Dugong oil from Australia. ANON. *Bull. Imp. Inst.* 23, 429-30(1925).—A sample of filtered oil had the following const.: d_{15}^{15} 0.9242, d_{15}^{100} 0.8622, n_D^{40} 1.458, α_D^{40} (200 mm. tube) -0.12° , solidifying point of fatty acids 34.6° , acid value 0.3, sapon. value 204.7, I value (Hübl, 17 hrs.) 52.3%, unsapon. matter 0.2, sol. volatile acids 0.3 cc. 0.1 N NaOH (for 5 g. oil), insol. volatile acids 16 cc. 0.1 N NaOH (for 5 g. of oil). These const. are in general agreement with those previously obtained for dugong oil, but the sapon. value is slightly higher and the I value slightly lower than the previously recorded figures. A. PAPINEAU-COUTURE

Highly unsaturated acids in ox-liver oil. KANESUKE KIMURA. *J. Soc. Chem. Ind. Japan* 28, 1366-73(1925).—An oily liquid obtained by direct heating of an ox liver in a pan is extd. with Et_2O and then treated with Me_2CO and alc. Ox-liver oil, yellowish brown cryst. soft mass and sol. in Et_2O and Me_2CO , thus obtained has the following properties: d_4^{100} 0.9008, acid value 36.5, sapon. value 128.3, I value 113.3, n_D^{60} 1.4720 and amt. of unsapon. matter 40.62%. Fatty acids (I) freed from the unsapon. matter: m. $39-42^\circ$, d_4^{100} 0.8437, neutralization value 196.3, I value 104.4, n_D^{60} 1.4480 and Et_2O -insol. bromides 19.2%. Fatty acids (II) from Me_2CO -insol. but alc.-sol. part: m. $48.5-51^\circ$, d_4^{100} 0.8515, neutralization value 188.6, I value 132.1, n_D^{60} 1.4522 and Et_2O -insol. bromides 30.0%. Fatty acids (III) from Me_2CO - and alc.-insol. part: m. $51-54.5^\circ$, d_4^{100} 0.8521, neutralization value 186.0, I value 143.5, n_D^{60} 1.4529 and Et_2O -insol. bromides 38.3%. Et_2O -insol. bromides from I, II and III have nearly the same compn. The bromides were debrominated. Highly unsatd. acids thus obtained were converted into Me esters and distd. Hydrogenated products of some fractions contained arachidic and behenic acids; the presence of $\text{C}_{20}\text{H}_{32}\text{O}_2$ (cf. Hartley, *C. A.* 1, 2901; 5, 518) and of $\text{C}_{22}\text{H}_{36}\text{O}_2$ was proved. Acids of the $\text{C}_n\text{H}_{2n-10}\text{O}_2$ series may be absent or in minute amt. if present. The odor of highly unsatd. acids from ox-liver oil resembles that from fish oil. K. K.

The mistake in the acid value of crude oils and fats, and the use of the impure acid value. TEI HIDAKA. *J. Soc. Chem. Ind. Japan* 28, 1374-81(1925).—H. proposed to use the term acid value in the following meaning: (1) *Total acid value* represents the acid value due to free fatty acids and impurities in the oils or fats. (2) *True acid value* represents the acid value due to free acids only. (3) *Impure acid value* represents the acid value due to the impurities other than free fatty acids. (1) is detd. by the usual method using the original oils or fats and (2) by the following method: Shake 50-100 cc. of the sample with 5-10% of H_2O for from 5 min. to 1 hr., till the mixt. becomes an emulsion. Filter through paper, obtaining clear oil. The acid value of this clear oil is (2) and by subtracting (2) from (1), (3) is obtained. The most convenient temp. for the treatment is $20-30^\circ$. Percentages of impurities are expressed by $K \times$ impure acid value. As the value of K , H. obtained 3.9-4 for pressed soy-bean or peanut oil, 8.0-9.0 for pressed perilla oil and 2.0-3.0 for pressed cottonseed oil. K. K.

The separation of ricinoleic acid from the mixed fatty acids of castor oil. KINJIRO INOKUCHI. *J. Soc. Chem. Ind. Japan* 28, 1353-8(1925).—In order to det. the conditions of the sepn. of ricinoleic acid from the castor-oil fatty acids by the Ba salt-alc. process, I. measured the soly. of Ba ricinoleate and stearate in alc.: Soly. of Ba ricinoleate in abs. alc.; 0.06 g. in 100 g. of the soln. at 10° , 0.13 g. at 20° , 0.325 g. at 30° , 2.00 g. at 40° , 9.372 g. at 50° and 28.19 g. at 60° . Soly. of Ba stearate in abs. alc.; trace at 10° , 20° and 30° , 0.014 g. at 40° , 0.018 g. at 50° and 0.024 g. at 60° . Soly. of Ba stearate in alc. of $d_4^{15} = 0.8119$; trace at 20° , 0.011 g. at 30° , 0.017 g. at 40° , 0.022 g. at 50° and 0.029 g. at 60° . Soly. of a mixt. of Ba stearate and ricinoleate; 0.127 g. at 20° , 0.324 g. at 30° , 2.141 g. at 40° and 9.511 g. at 50° . The conditions for the prepn. of pure ricinoleic acid from castor oil: The temp. for the sepn. of the Ba salts is 50° ; the time given for dissolving the mixed Ba salts in the solvent is about 1 hr. to take advantage of the poor and difficult soly. of Ba stearate; the solvent should first be somewhat watery (say 95% alc. by wt.), then 98% and at last abs. alc.; the amt. of alc. used for one sepn. may be about 100 cc. for each 10 g. of the salts. K. K.

Studies on catalytic hydrogenation of highly unsaturated acids. I. The course of hydrogenation of methyl esters of highly unsaturated acids in the presence of nickel catalyst. YOSHIYUKI TOYAMA AND TOMOTARO TSUCHIYA. *J. Soc. Chem. Ind. Japan* 28, 1079-87(1925).—Methyl esters of highly unsatd. acids, obtained from Japanese sardine oil, have been hydrogenated in the presence of Ni at 185-210° under ordinary pressure. The ester b_p 210-27°, sapon. value 169.2, I value 350.6; the fatty acids obtained from the ester yield 127.1% of Et₂O-insol. bromide contg. 71.06% Br. The individual acids which may possibly be present in the original sample are C₂₀H₃₀O₂, C₂₂H₃₄O₂, C₂₀H₃₂O₂ and C₂₂H₃₆O₂. Before the I value of the original sample falls to 11.4, portions are taken out at 12 different stages of hydrogenation and analyzed. The amt. of the fatty acid giving Et₂O-insol. bromide steadily decreases according to the progress of hydrogenation. Thus when the I value of the acid becomes 173.1, the amt. of Et₂O-insol. bromide is 1.67% and at 134.9 of the iodine value, no bromide is produced. As the Br content of Et₂O-insol. bromide is found to be more than 69% in every case, no fatty acids giving Et₂O-insol. hexabromide can be found in substantial amt. during the entire course of hydrogenation. The fact that the Br content of Et₂O-insol. bromide decreases a little with the progress of hydrogenation may be accounted for by partial conversion of the fatty acids of five double bonds to those of four double bonds. Until nearly all of the fatty acids giving Et₂O-insol. bromide disappear, no distinct amt. of solid acid is formed. Immediately after almost complete disappearance of fatty acids giving Et₂O-insol. bromide, solid acids are formed in substantial amt. As it can reasonably be assumed that most of the fatty acids (C₂₀ and C₂₂) of one double bond formed during the hydrogenation are solids it appears that until nearly all of the fatty acids giving Et₂O-insol. bromide disappear, the hydrogenation results mainly in the conversion of highly unsatd. acids to acids of two double bonds. Immediately after almost complete disappearance of fatty acids giving Et₂O-insol. bromide, the conversion of the acids of two double bonds to those of one double bond with the formation also of satd. acids takes place mainly. Even in the sample having an I value of 134.9, the presence of satd. acids is indicated. It is found that the solid acids of one double bond formed during the hydrogenation contain those having markedly higher m. ps than naturally occurring C₂₀ and C₂₂ acids of the oleic series. Even the presence of solid acids of two double bonds is indicated. K. K.

The formation of the iso-unsaturated solid acids during the hydrogenation of fatty oils. I. Presence of iso-acids in hardened sardine oil. SEI-ICHI UENO. *J. Soc. Chem. Ind. Japan* 28, 1235-9(1925); cf. *Ibid* 27, 23(1924).—U. has examd. the original and hardened sardine oils as to the formation of iso-acids during hydrogenation of the oil at a high temp (160-182°) with Ni catalyst. Solid acids sepd. from the original sardine oil by the Pb-soap-Et₂O process have a high I value. The original sardine oil should contain iso-compds. of unsatd. acids. Properties of the solid and liquid acid, sepd. from some samples of the selectively hardened oil, are similar and the neutralization value of the former is pronouncedly higher than that of the latter. The hydrogenation takes place in a selective manner in regard to the mol. wt. of the unsatd. fatty acids; the higher acid is more slowly reduced than the lower. Some portions of highly unsatd. fatty acids, in the first stage of the hydrogenation, are changed into the iso-acid of the oleic series and then to the satd. series. All samples of the soft hardened oils do not contain the highly unsatd. fatty acids which are completely satd. more readily than those of the oleic acid series. K. KASHIMA

Constants of Victorian beeswax. Graph for the investigation of beeswaxes. A. A. WEIR. *Analyst* 50, 445(1925).—By making a graph showing the various possible consts. of pure beeswax (sp. gr., m. p., n_D , I₂ value, sapon. value, acid value, ester value, inverse ratio of the last 2 values, and unsaponifiable value) and plotting also the corresponding consts. of the possible adulterants, it was easy to establish the fact that the given sample was pure. W. T. H.

Soap and solvent (detergent) mixtures. C. F. GREEN. *Textile Colorist* 47, 788-9(1925).—The relative values of these mixts. may be approximated from simple tests of their power to wet-out and emulsifying action. CHAS. E. MULLIN

Naphthenic soap. JIRO MIKUMO. *J. Soc. Chem. Ind. Japan* 28, 1121-6(1925).—Na soap prepd. from a mixt. of Japanese naphthenic acids ($d_4^{25} = 0.9708$, acid value 249.2) was examd. for its soap characteristic, i. e., surface and interfacial tensions, emulsifying, lathering and detergent powers. Parallel tests were made with Na soaps from Kahlbaum's oleic acid, coconut oil and rosin. The naphthenic soap is extremely sol. in cold H₂O and has great lathering power, even more than coconut oil soap. It is, however, soft and is far poorer than oleate soap in cleansing activity. It stands between fatty and rosin soaps. K. KASHIMA

Densities and inner friction of glycerol solutions (HERZ, WEGNER) 2. Effect of tapping coconut palms for toddy on the copra and oil from subsequent fruiting (JACK, DENNETT) 11D. Apparatus for clarification of oil. AKTIESELSKAPET FORSOEKSDRIFT. Norw. 41,935, Sept. 28, 1925. Mech. features. The clarifying vessel is kept completely full during the operation by means of a layer of water which at the same time will take up the sepd. impurities.

Rotary filter for separating oils or fats from aqueous liquids. E. F. SPANNER. Brit. 233,738, Nov. 15, 1923.

Apparatus for making soap. A. T. MIRZA. Brit. 234,346. Sept. 23, 1924. The app. comprises an autoclave in which ingredients injected through a sprayer are agitated while heated at about 113°, a cooler, salting-out pan and connections and other accessory app.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Report on meeting of Technical Advisers in the Java Sugar Industry, August 4, 1925. ANON. *Arch. Suikerind.* 33, Part 4(1925); cf. C. A. 19, 2754; 20, 120. Meeting of Agricultural Section, 137–88.—A round-table discussion on the field results of the 1924–25 campaign, and on the following points in connection with the 1925–26 crop: prepn. of land, planting, depth of planting, sources of seed cane, distance between plants, fertilizers, production of seed cane, diseases, insects and varieties. F. W. Z.

Report on meeting of Technical Advisers in the Java Sugar Industry; meeting of Agricultural Section, Aug. 5, 1925. ANON. *Arch. Suikerind.* 33, Part 4, 189–244 (1925); cf. C. A. 20, 120.—A round-table discussion on fertilizers, green manuring, supply of seed cane, warm water treatment of seed cane, diseases and insects. F. W. Z.

How large should the unknown losses be in a raw-sugar or mixed mill? WILHELM GREDINGER. *Deut. Zuckerind.* 50, 1597–8(1925).—Total losses (a), known losses (b) and unknown losses (c), for G.'s factory producing both raw and refined sugars, in % on beets, were: campaign of 1922–3, (a) 0.75, (b) 0.37, (c) 0.38; 1923–4, (a) 0.73, (b) 0.33, (c) 0.40; 1924–5 (a long and mild season with very poor beets), (a) 0.91, (b) 0.41, (c) 0.50. In contrast with this the losses in 2 raw-sugar mills having poor control were: (a) 1.34, 1.52, (b) 0.35, 0.38, (c) 0.99, 1.14.

W. L. BADGER

Practical application of bromothymol blue. C. FRANSSEN. *Arch. Suikerind.* 33, 1230(1925).—In a Java sugar factory the juice was, toward the end of the campaign, sulfured and limed to p_H 7, with this indicator. Ordinary titrations of the same juices with phenolphthalein as indicator usually showed between 130 and 180 mg. SO_2 per l. with an even greater variation in some cases, against 70–90 mg. per l. in the usual procedure. In spite of this no inversion could be detected. Liming to p_H 7 resulted in less filter-press mud. The juice obtained was not quite as brilliant, and boiling to grain was less easy to perform. However, there was no difficulty in purging.

F. W. ZERBAN

The behavior of raffinose in crystallizing processes. G. SCHECKER. *Deut. Zuckerind.* 50, 1474, 1499(1925); cf. Mehrle, C. A. 20, 306; Richard Mehrle, *Ibid* 1455, 1522, 1574.—Polemic.

W. L. BADGER

Precipitation of calcium sulfite under various conditions, with special reference to sugar factories. R. G. W. FARNELL. *J. Soc. Chem. Ind.* 44, 530–2T, 533–8T(1925); *Intern. Sugar J.* 28, 36–45(1926).—Previous literature is reviewed. The neutralization curve for 0.046 N solns. of H_2SO_3 and $Ca(OH)_2$ has been constructed for 20°, and also after boiling and quickly cooling. When 50% neutralization is exceeded, $CaSO_3$ is formed and partly pptd.; below this point boiling drives out some SO_2 , but above it the effect is merely an increased pptn. of $CaSO_3$. The p_H of 0.023 N $Ca(HSO_3)_2$ is 4.8, that of 0.005 N $CaSO_3$ is 9.2. Between 55 and 80% neutralization there is a strong buffer effect, the p_H remaining nearly const. at 5.2–5.3. Pptn. of Ca as $CaSO_3$ increases with time of heating at any given temp. The max. pptn. is reached when the p_H is at least 8. A pptn. of 94.6% may be attained by boiling and then keeping the temp. at 90–100° for 1 hr. In the presence of sucrose the pptn. of $CaSO_3$ is retarded at low temps., but above 70° the effect becomes negligible. The crystals ($CaSO_3 \cdot 2H_2O$) are smaller than in aq. soln., but otherwise of the same character. If colloids are

present besides sucrose, the pptn. of CaSO_3 is greatly retarded and becomes a function also of the SO_2 originally present; here the ppt. consists of spherical particles instead of needles, their size increasing with the p_H attained. In factory practice at least 0.5 g. SO_2 per l. should be used; 2 g. gives a better clarification effect and less scale in the evaporators than 1 g., the juice being limed in both cases to the same p_H . This confirms results of Brewster and Raines (*C. A.* 16, 4360). Better results would be obtained if liming were carried to p_H 7.6-7.8, instead of to 6.8 as now practiced in Natal and Mauritius. Of course, the capacity of the filter-press station would have to be increased in that case.

F. W. ZERBAN

Decolorizing carbons. A. A. BŁOWSKI AND J. H. BON. *Ind. Eng. Chem.* 18, 32-42(1926).—On the basis of exhaustive lab. tests with 5 decolorizing carbons, regarding the decolorizing efficiency, filtration efficiency and removal of ash for various refinery products and under varying conditions, it is concluded that these carbons do not, either as a substitute for or as an adjunct to bone char, offer sufficient technical and economic advantages at the present time to justify their adoption for cane-sugar refining on a large scale. They may be profitably used for a restricted trade, but a large amt. of study and investigation on a factory scale will be necessary before they may obtain a more favorable standing from the view-point of the large U. S. refiner. The exptl. results are shown in numerous tables and charts.

F. W. ZERBAN

The significance of active carbons for the production of sand sugar from thick juice. A. LINSBAUER. *Z. Zuckerind. czechoslov. Rep.* 50, 49-53, 56-60(1925). A lecture

W. L. BADGER

Hydrogen-ion concentration as a basis of refinery alkalinity control. A. A. BŁOWSKI AND A. L. HOLVEN. *Ind. Eng. Chem.* 17, 1263-6(1925).—Acidities and alkalinities of refinery products detd. by titration with the usual indicators are misleading as shown by a no. of tests. To reduce inversion losses to a min., the H-ion concn. must be detd. and kept as closely as possible to p_H 7. A practical spot plate test has been developed, with color charts of dyed gelatin-coated celluloid. H-ion control by this method is maintained throughout the factory, and wherever practicable, acidity is corrected by adding milk of lime of 2° Brix to p_H 7. This system has reduced the total amt. of lime used to one-half, and has increased the recovery of crystd. sucrose.

F. W. ZERBAN

The nipa palm as a source of sugar and alcohol. M. REIJGERSBERGH. *Arch. Suikerind.* 33, 1244-53(1925).—A brief description is given of the occurrence and habits of growth of this palm, and of the methods used for tapping. About 12,000 l. of juice, contg. 15% sucrose, is produced per acre. For alc. production the juice as obtained by ordinary tapping is fermented and distd. Losses are as much as 50%, as the juice sours before reaching the distillery. The yield is about 750-900 l. alc. per acre. For sugar production the effect of the invertase and oxidase in the fresh sap is counteracted by the use of lime and Ca sulfite in the collecting vessels. The juice is then worked up by the usual methods for producing white plantation sugars. The difficulty in the removal of albuminoid material can be largely overcome by first heating the raw juice to boiling, cooling and decanting, after which it is clarified and further treated as usual. The product is practically white, and has a characteristic, agreeable flavor. The sugar yield is about 1400 kg. per acre.

F. W. ZERBAN

Notes on the use of Soldaini's reagent. R. OFNER. *Z. Zuckerind. czechoslov. Rep.* 50, 53-4(1925); cf. *C. A.* 19, 583, 3029.—It is necessary to use a CaCl_2 bath and actually to boil the sample, and to use O.'s modification of the reagent.

The drying of sugar cane and beets. V. KHAINOVSKY. *Arch. Suikerind.* 33, 1175-85(1925).—A review of previous literature.

F. W. ZERBAN

Further data on air removal from pressed beet juices, and on Herles' method of clarification for the analysis of pressed juice. FERDINAND KRYŽ. *Z. Zuckerind. czechoslov. Rep.* 50, 54-6(1925).—The figures given in *C. A.* 19, 3612, for the differences in d. caused by thorough removal of air, have been criticized as excessive. The original expts. were done on badly rotted beets. Figures taken during the campaign on juice from fresh beets pulped with the Staněk rasp show from 1° to 10° Bx. higher readings after air removal. In the analysis of 10 samples of press juice, clarified with Herles' reagent and with $\text{Pb}(\text{OAc})_2$, no differences were found in 6 samples, and only $\pm 0.1^\circ$ in the other 4. Hence the work of Ofner (*C. A.* 19, 3029) and that of Weiss (*C. A.* 19, 3612) have no bearing on this case.

W. L. BADGER

The utilization of sweet-corn cobs. G. G. NAUDAIN. *Am. Food J.* 20, 508(1925).—The juice from sweet-corn cobs contains sufficient sugar to warrant its utilization. Expts. indicate that the tannin compds. can be removed by such materials as decolorizing C. Phthalic anhydride in alk. soln. is the most delicate test for tannin compds.

J. A. KENNEDY

Chemical constitution of the gum from *Boswellia serrata*. M. A. MALANDKAR. *J. Indian Inst. Sci.* **8A**, 240-3(1925).—The gum was hydrolyzed by heating on a water bath for 8 hrs. with 3% H_2SO_4 . An EtOH-insol. residue proved to be the gum acid. On further heating with acid this gradually decreased in mol. wt. as judged by the Ba content of its salt. Arabinose, xylose and galactose were identified in the EtOH-sol. portion. J. J. WILLAMAN

ALLEN ROGERS

The history of tanning and tanning chemistry. TH. KÖRNER. *Ledertech. Rundschau* **17**, 177-80, 191-3, 202-4(1925).—The work in the 18th century of Newmann and of Lemery on the iron-tannin reaction and the search for tannin-bearing materials during the last 2 centuries is reviewed. I. D. C.

New tanning materials and sundries. LEOPOLD POLIAK. *Gerber* **51**, 213-4 (1925); cf. *C. A.* **20**, 308.—Description and analyses of the following proprietary products: *Anti-oxydul*; *Pellastol C*; and *Pellastol N*. H. B. MERRILL

Syntans. OTTO ZOHLEN. *Gerber* **51**, 201-4(1925).—A description. H. B. M.

Modifications brought about by the war in the French industry of leather treating materials. MARCEL GILLET. *Rev. chim. ind.* **34**, 338-41, 370-3(1925); cf. *C. A.* **19**, 3034. A. PAPINEAU-COUTURE

Another important role played by enzymes in bating. J. A. WILSON AND H. B. MERRILL. *Ind. Eng. Chem.* **18**, 185-8(1926).—An important function of bating is the removal of keratose from the skins by hydrolysis with pancreatin, which proceeds only in the p_H range 5.5 to 11.2, with a max. at 7.9. The isoelec. point of keratose is at $p_H = 4.1$. Hydrolysis at 40° and $p_H = 7.9$ has been measured as a function of time and concn. of both enzyme and keratose. A method is outlined for measuring the keratose-digesting power of bating materials. J. A. WILSON

Ultrafiltration of vegetable tanning solutions. A. W. THOMAS AND MARGARET W. KELLY. *Ind. Eng. Chem.* **18**, 136-8(1926).—Ultrafiltration is not a reliable method for sepg. tannins from nontannin because the fraction of total material retained by the colloidion ultrafilter was found to vary widely with p_H value and with the concn. of colloidion used in the prepn. of the membrane. J. A. WILSON

Report of the International Commission on the Analysis of Chrome Leathers and Chrome Liquors. R. F. INNES, *et al.* *J. Intern. Soc. Leather Trades Chem.* **9**, 508-9 (1925).—Proposed changes in methods are discussed. H. B. MERRILL

Preparation of hide powder for analytical work. L. MEUNIER, P. CHAMBARD AND A. JAMET. *J. Intern. Soc. Leather Trades Chem.* **9**, 510-2(1925); cf. *C. A.* **19**, 747, 2143.—The best and most economical starting material is cow-hide flanks. Previous work on deliming is reviewed. Disintegration is best accomplished after dehydrating with 85% acetone and drying at 30°. H. B. MERRILL

The destruction of leather by microorganisms. F. SCHMIDT. *Ledertech. Rundschau* **17**, 185-6(1925).—Four photomicrographs are given of leather damaged by bacteria. I. D. C.

Dyeing of leather tanned with synthetic tannins. G. E. KNOWLES. *J. Intern. Soc. Leather Trades Chem.* 9, 512-7(1925).—See C. A. 19, 3385. H. B. MERRILL

Leather dyeing. I. H. SALT. *J. Intern. Soc. Leather Trades Chem.* 9, 518-20 (1925).—The addition of NaCl or Na₂SO₄ to the dye bath, in using acid dyes without added acid, interferes with the fixation of the color by sumac skivers. Acetic acid added to the bath gives results as good as those obtained with H₂SO₄. II. H. SALT AND D. McCANDLISH. *Ibid* 520-5.—Chrome leather has a much greater affinity for acid and direct dyes, and a much smaller affinity for basic dyes than vegetable-tanned leather or chrome leather mordanted with sumac. The usefulness of sumac mordanting in dyeing chrome leather is due to a retardation of dye fixation, resulting in more even shades. H. B. MERRILL

Polishing wheel leather. R. C. BOWKER. *Abrasive Ind.* 7, 14-5(1926).—Chem. analysis of some American sole leather, which gave poor results when used for rough polishing, showed a high grease content. Imported leather giving satisfaction showed a low grease content and the presence of CrO₃. It was established by tests that domestic leather prep'd. by a combination of the chrome and vegetable processes and contg. less than 0.5% of grease gave excellent results in rough polishing of cutlery blades. W. H. BOYNTON

Protective measures against the spread of anthrax by tanneries. WILHELM RIECK. *Ledertech. Rundschau* 17, 173-7, 186-90(1925).—Statistics show the no. of anthrax cases for several years. Methods for testing skins for anthrax and for disinfecting them are given. Imported skins should be exam'd. and disinfected at the port of entry. If infected hides are used, all tannery wastes and effluent must be disinfected or the disease will spread to the pasture land. I. D. CLARKE

Rendering gelatin insoluble with formaldehyde at moderate temperature in presence of sulfonate. ALBERT BRYLINSKI. *Bull. soc. ind. Mulhouse* 91, 611-2(1925). Sealed Note 2054 of Dec. 9, 1910.—According to the Fr. pat. 413,007, addn. of an org. acid to a bath contg. gelatin and CH₂O prevents the insolubilization, which is restored by NH₃. In order to eliminate the successive acid and alk. treatment which can be harmful with certain dyes, B. uses neutral Turkey red oil (com. 50% NH₃ sulfo oil) as follows: pass the fabric successively through a gelatin bath and through a bath contg. the sulfo oil and CH₂O, and dry as usual. By reversing the order of the baths a superficial insol. dressing is obtained. Insolubilization occurs in 1.5 hrs. at room temp., and in a few min. at 40-50°. Report. PHILIPPE BRANDT. *Ibid* 613-4.—The results claimed were readily duplicated. On heating the neutral sulfo oil for several hrs. at 50° with CH₂O, or on allowing to stand several hrs. in the cold, there is formed some hexamethylenetetramine, which has no action on gelatin but interferes with the reaction by using up some of the CH₂O. The sulfo oil acts merely as an accelerator, and other colloids (Na sulfonate, monol soap, Na oleate, gum senegal, protectol, albumin, starch paste, linseed oil emulsion) behave similarly. The coagulum is similar in every respect to that obtained with gelatin and CH₂O alone, except that the former is milky in appearance. The coagulum is insol. even in boiling H₂O, but is slowly attacked if it has not been previously dried. It is decomposed by prolonged digestion with cold 15% HCl. No priority for the process was found. A. PAPINEAU-COUTURE

Colored patent leather. W. C. WELCH. U. S. 1,569,056, Jan. 12. Patent leather is formed by successive applications of japanner's varnish to the leather and a powd. coloring material such as bronze powder is applied and firmly fixed in the surface of one of these coatings.

Leather grease. PAUL SKAUG. Norw. 41,999, Oct. 12, 1925. A mixt. of fat or paraffin wax, water-sol. soap and less than 50% of a liquid fat-solvent.

Stencil dyeing of leather. W. MOOG. U. S. 1,569,562, Jan. 12. Mech. features.

Autolyzed yeast in leather manufacture. D. McCANDLISH and W. R. ATKIN. U. S. 1,570,383, Jan. 19. An aq. soln. of autolyzed yeast is applied to hides, kips or skins as a substitute for pancreas tryptase for softening dried hides, depilating, bating and puering.

Tanning composition. O. RÖHM. U. S. 1,569,578, Jan. 12. Sulfite cellulose liquor is mixed with Fe chloride or other Fe salt and with an alkali metal silicate to form a compn. which produces leather of good weight and color.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Calender and shrinkage effects of unvulcanized rubber. W. DE VISSER. *Dissertation Delft* 1925, 147 pp.; *Gummi-Ztg.* 40, 457-8, 511-3(1925).—A systematic investigation was made of the factors which influence the calender effect (*c. e.*), the latter being characterized by a difference in the stress-strain curves across and along the direction of calendering of a sheet. The stress increases steadily with the elongation in the direction of calendering, but remains almost const. with increase in elongation across the direction of calendering. From these relations a *diagrammatical method for estg. the intensity of the c. e.* is derived. The tensile strength (based on the original cross-section) is greater along than across the direction of calendering, whereas the max. elongation is greater across. These differences are also manifest in changes in 3 dimensions on warming or on dissolution in a solvent, the length decreasing, the width and thickness increasing. These last phenomena, however, occur at times in sheets in which the *c. e.* is absent. With const. conditions otherwise, the *c. e.* decreases with an increase in the plasticity of the rubber and also with an increase in the temp. (1) of the lower roll, (2) of the upper and middle rolls and (3) of the rubber before calendering, all of which indicate a relation between plasticity and the *c. e.* A *c. e.* is also found in gutta-percha, balata, *Castilloa* and *Ficus elastica*. Nine methods of calendering were carried out with rubber plasticized to a const. degree and brought to 80°, the upper and middle rolls also being maintained at 80°. In all cases the sheets were first passed between the upper and middle rolls. (1) With no other treatment a *c. e.* was absent. (2) After passing around the middle roll and out between the middle and lower roll, a *c. e.* was absent. (3) After passing around the middle roll, between the middle and lower rolls and around the lower roll (hot), a *c. e.* was absent. (4) Under conditions like (2) except for rolling the sheets immediately in linings (without pressure between the lower rolls) a *c. e.* was evident. (5) Under conditions like (3) except for a cold lower roll, a strong *c. e.* was produced. (6) Under conditions like (2) except for passing the sheets immediately into cold water, a *c. e.* was absent. (7) Under conditions like (1) except for rolling immediately in linings a distinct *c. e.* was produced. (8) Under conditions like (7) except for preheating the linings at 80°, a *c. e.* was absent. (9) Under conditions like (3) and like (5) except for stopping the calender and allowing the rubber to remain in contact with the lower roll (either hot or cold) there was no *c. e.* The results indicate that a *c. e.* is produced only when the rubber is cooled instantly after calendering and free motion is inhibited. Furthermore, this effect is produced between the upper and middle rolls. By means of geometrical figures of known dimensions on the upper roll, which imparted impressions to the calendered sheet, it was shown that when free motion after calendering preheated rubber was permitted, shrinkage and full recovery occurred, but that when shrinkage was prevented, the figures remained enlarged in their original proportionate dimensions and a *c. e.* was produced. On calendering rubber not first preheated the phenomena were far different, differential motion between the inner and outer strata occurring. When rubber at 80° was stretched and while stretched instantly either rolled in cold cloth or held on a cold glass plate, there was no *c. e.* But with the rubber at room temp. a *c. e.* was produced. The effect was also produced by compressing to thin sheets. Further expts. showed that the degree to which calendered rubber shrinks bears no simple relation to the *c. e.* Rubber manifesting the *c. e.* also shows double refraction on polarization, corresponding to a positively refracting uniaxial crystal, whose optical axis lies in the direction of calendering. This double refraction disappears with the *c. e.* even when a shrinkage effect can be detected. Dichroism also accompanies a *c. e.* A diminution in d. occurs when the *c. e.* disappears (cf. Feuchter, *C. A.* 19, 2575). Rubber in which the *c. e.* is pronounced becomes hard and brittle rapidly compared with that in which it is absent. Furthermore rubber with the *c. e.* gives a *Debye-Scherrer Röntgen diagram*, whereas rubber showing only a shrinkage effect gives an *amorphous ring*, indicating that the *c. e.* depends on the formation of an ordered structure which probably involves formation of a cryst. phase. The shrinkage effect can be explained in the way that Lunn (*C. A.* 18, 1764) or Hauser and van Rossem sought to explain the *c. e.*, though according to de W., inadequately.

The rubber industry. JEAN-CH. BONGRAND. *Chimie et industrie* 14, 823-38

(1925).--Review of the origin, properties, methods of collection, processes of transformation and chief chem. researches carried out in rubber, pointing out lines of further research. Bibliography of 115 references. A. PAPINEAU-COUTURE

Developments in the preparation of raw rubber. W. S. DAVEY. *Trans. Inst. Rubber Ind.* 1, 261-7(1925).--A review of methods involving coagulants, evapn. and electrodeposition. Discussion. D. F. TWISS, *et al.* *Ibid* 267-9. C. C. DAVIS

Gas black for rubber manufacture. The effects and detection of grit. G. GALLIE. *Trans. Inst. Rubber Ind.* 1, 247-53(1925).--Gritty particles, which originate from deposits which have passed through the mfg. process repeatedly and have burned to hard flakes, are a frequent impurity in gas black. Expts. show that they contain at times several % of ash and more Me_2CO -sol. and petr. ether-sol. components than the fine component. Part of this grit is not disintegrated during ordinary milling and that which remains is uniformly distributed and reduces the tensile strength of the vulcanized rubber contg. it. Furthermore when it is finely ground it acts as a filler with no reinforcing power. Discussion. D. F. TWISS, *et al.* *Ibid* 253-4. X-ray examn. of gas black in bag form is useful in detecting grit. C. C. DAVIS

The two-phase structure of rubber. II. ERNST A. HAUSER. *Rev. gén. colloïdes* 3, 321-4(1925); cf. *C. A.* 20, 667.--The opinion is held that the internal phase of rubber globules (cf. *C. A.* 19, 1962, 2280) is the rubber hydrocarbon in gel form in which a more highly polymerized form is dispersed. This membrane on the contrary is a gel in which this more highly polymerized form is the predominant component. The origin of this membrane, which is particularly firm in *Ficus elastica*, is unknown, but there may be some relation between its origin and the fact that when a drop of H_2O is placed on a C_6H_6 soln. of rubber, there forms at the surface of contact a milky turbidity which can be removed by a needle as a delicate membrane. The Röntgen spectrogram of rubber attributed by Katz (cf. *C. A.* 19, 2144, 2424, 2759) to crystn. is more easily explained by polymerization, particularly since the phenomenon is reversible. Likewise the concept advanced by Hock (*C. A.* 19, 3036) can be more simply explained by polymerization. A review and discussion of the subject in general are included, with 21 references. C. C. DAVIS

Tendencies in rubber compounding. W. B. WIEGAND. *India Rubber J.* 70, 900-2, 933-8(1925).--A discussion dealing with the materials and methods of modern compounding and replete with suggestions for improving present the methods (cf. Wiegand, *C. A.* 19, 2423, 3386). Reinforcement may be visualized in terms of *anchorage, continuity of stress and uniformity of stress*. The finer the pigment the greater the surface energy developed between the pigment and rubber and the greater the bond between each. With inert fillers, *e. g.*, whiting and barytes, this bond is insufficient to withstand stresses and the rubber phase seps. from the particles in the direction of major stress, with formation of vacuoles. As deformation increases, the particles are subjected to compression due to lateral contraction and the rubber phase between the particles is compressed thinner and thinner and eventually ruptures. With a reinforcing pigment the greater surface energy prevents the tension in the rubber phase from sepg. the rubber-pigment surface. Each particle assumes its share of the stress and the lines of stress pass through instead of around the particle. The finer the pigment the less this sepn. between rubber and pigment. Furthermore the particles are of uniform size and there is a balanced state of stress throughout the rubber matrix, each unit sustaining similar stresses and strains through the whole range of extension. This explains the high proof resilience of gas black mixings at intermediate elongations. It is suggested that the Joule effect in rubber is analogous to the gas laws, both in principles and formulas, and that a common basis rests on the fact that part of the energy expended in stretching rubber becomes reversible heat which is recoverable on retraction. Furthermore the stress-strain curves are analogous to the pressure-vol. curves of a gas, and since, as the temp. increases the former curves approach the load axis and the isotherms of a gas move up toward the pressure axis, a cycle of changes occurs with rubber which correspond to Carnot's cycle. Thus if rubber is contracted isothermally by an increase of temp. with absorption of heat, is cooled at const. elongation, is then stretched isothermally with consequent evolution of heat and finally is heated at const. elongation to its original temp., then theoretically the original state is resumed. When the Joule effect is large enough in relation to the frictional heat it is possible to construct a *rubber heat engine* (cf. W., *India Rubber World* 73, 200(1925)). Practically also these principles govern the compounding of rubber mixts. to obtain a linear stress-strain curve (cf. *C. A.* 19, 2423), max. resilient energy and resistance to abrasion, a ΔA function (cf. *C. A.* 19, 3386) far greater than at present and elimination of hysteresis and grain effect. Such improved mixts. have a greater capacity for storing energy than

any other structural material and are capable of a variety of uses hitherto impracticable.

C. C. DAVIS

Tensile strength of cold-cured rubber. ALBERT ZEITLIN. *Trans. Inst. Rubber Ind.* 1, 255-9(1925).—Detns. were made of the phys. properties of pale crepe cured for various periods up to 120 sec. in 1-5% CS_2 solus. of S_2Cl_2 . Immediately after curing the samples were immersed momentarily in CS_2 to remove excess S_2Cl_2 . The effect of increasing the time of immersion in S_2Cl_2 was similar to the effect of increasing the concn. of the % S in hot vulcanization. Most of the tensile strengths were 1200-1800 lbs. per sq. in. and the ultimate elongations 800-1000%. A cure of 7 sec. in 1% S_2Cl_2 , however, gave 2550 lbs. per sq. in. and 910%. The stress-strain curves were similar to those of similar mixts. vulcanized by the hot process. With C_6H_6 as solvent instead of CS_2 , the rate of cure was slower. Discussion. D. F. TWISS, et al. *Ibid* 259-60.

C. C. DAVIS

Further data on matured rubber. O. de VRIES AND W. SPOON. *Arch. Rubber-cultuur* 9, 849-99(1925); (In English, *Ibid* 900-8); cf. *C. A.* 13, 916.—The prepn. of slab rubber is advantageous to estates beginning production, and one estate in Java preps. 150-300 tons per year. Coagula matured for 2 and for 10 days vulcanized at the same rate. The addn. of disinfectants to the latex or soaking the slabs in disinfectant solns improved the odor of the rubber and prevented the formation of a slimy surface, but did not prevent maturation. No maturation took place after coagulation with EtOH . Coagulum matured in the air absorbed O, in one case about 0.25% of the wt. of the dry rubber. Gases formed in the coagulum kept under H_2O were mainly CO_2 with smaller quantities of N and of an inflammable gas and a trace of H_2S . Matured rubber from trees which had been rested cured relatively slowly. For 193 samples of matured rubber the mean deviation from the mean time of cure was 18.8% while the deviations for smoked sheet and for crepe were 11.6 and 6.66%, resp. Cf. also Brunl, *C. A.* 20, 309.

F. H. YORSTON

Rate of combination of sulfur with rubber in hard rubber. W. E. GLANCY, D. D. WRIGHT AND K. H. OON. *Ind. Eng. Chem.* 18, 73-5(1926).—In continuation of previous work (*C. A.* 18, 1763) a mixt. of rubber 70, S 30 with and without the addn. of different accelerators was used to study the amt. of S necessary to convert a rubber mixt. to the hard form and the effect of org. accelerators on the coeff. of vulcanization and on the tensile strength. As vulcanization proceeds, the phys. properties change rapidly only when the coeff. of vulcanization reaches about 23.5, which corresponds to $\text{C}_{10}\text{H}_{16}\text{S}$. No $\text{C}_{10}\text{H}_{16}\text{S}_2$ is apparently formed until the formation of $\text{C}_{10}\text{H}_{16}\text{S}$ is complete. Org. accelerators increase the rate of combination of rubber and S, without however increasing, as in soft vulcanizates, the tensile strength of the final product. Each accelerator regulates in a different way this combination of rubber and S. ZnO is not essential for activation with diphenylguanidine. A loss of S occurs during vulcanization, the loss averaging 0.4% with rubber and S alone but less when org. accelerators are present. The vol. of hard rubber is less than the vol. of the original ingredients. C. C. DAVIS

Theory of the Joule effect in rubber. LOTHAR HOCK. *Z. Elektrochem.* 31, 404-9(1925); cf. *C. A.* 18, 3490.—Evidence is presented for the view that the Joule effect in rubber is due to heat of compression of the internal latex fluid on stretching. X-ray measurements of Stintzing have confirmed the theory previously expressed that the restoring force produced by mech. deformation is localized in the arrangement of the particles analogous to optical anisotropy.

H. R. MOORE

Oxidation tests for rubber goods. F. PERITOR. *Gummi-Ztg.* 40, 94(1925).—Exposure of rubber simultaneously to ultra-violet light and to air contg. a high amt. of O_2 causes such a rapid deterioration that the effects of several months' exposure to sun and air under natural conditions can be duplicated in a few moments. A simple app. supplying O contg. 25% O_2 consists of a negative electrode such as a storage battery plate or a C of large surface area, a Pt point as positive electrode and 20% H_2SO_4 as electrolyte. The current is supplied by a no. of storage batteries or by a high-tension current, with the introduction of suitable resistance to yield a current of high amperage. The O_2 is collected by displacement in a cylinder over the positive electrode. By shutting off the bell jar from the cylinder, with the current on, O_2 is collected in the cylinder under pressure, the cylinder also serving as a gage of the vol. of activated O supplied to the samples. When the connection is opened, the same vol. of O_2 always enters the bell jar contg. the samples. The cylinder may be graduated for greater accuracy. The activated O is maintained in contact with the rubber a definite time and the relative deterioration detd. or until the samples are ruptured if exposed under tension.

Coagulation with sodium fluosilicate in conjunction with *p*-nitrophenol. H. P.

STEVENS. *Bull. Rubber Growers' Assoc.* **7**, 657-8(1925).—Latex coagulated with *p*-nitrophenol and Na_2SiF_6 , which had been ground together, gave a rubber which vulcanized as quickly as did a control prep'd. with HOAc. F. H. YORSTON

Single texture finishes. S. G. BYAM. *India Rubber J.* **70**, 1143-4(1925); *India Rubber World* **73**, 76-7.—A description of present methods of obtaining various finishes by means of starch, mica, varnishes, etc., and their relation to different methods of curing. C. C. DAVIS

Dielectric constant, power factor and resistivity of rubber and gutta-percha. H. L. CURTIS AND A. T. MCPHERSON. *Bur. Standards, Tech. Paper No.* **299**, 669-722 (1925).—The object of the expts. was to det. the relative suitability of raw rubber (I), vulcanized rubber (II) and gutta-percha (III) as insulators in submarine cables. The principles and technic of the methods employed in the measurements and the app. are described and illustrated in detail. The dielec. const. (d. c.), power factor (p. f.) and resistivity (r.) each depended upon the external pressure and the d. c. and p. f. on the frequency. In all cases the d. c. and p. f. increased with decrease in frequency. The d. c. of III decreased with increase of pressure, whereas an increase occurred in all samples of I. The p. f. and r. increased with the pressure in all cases except hard rubber, where they decreased with increase of pressure. The d. c. of I was less than that of III. The type of I had little influence, but wide variations occurred among samples of III. In each case the more nearly the compn. approached that of the base hydrocarbon the lower the d. c. The lowest value of I was 2.35 and of III 2.58. Dry com. I gave values up to 2.60, III (57% gutta) 3.0 and balata (45% gutta) 3.5. The accessory components caused the high values and I contg. unusually high amts., e. g., sprayed latex I and guayule, had a high d. c. and p. f. Removal of H_2O -sol. components therefore reduced the d. c. Vulcanization increased the d. c. of I, this increase depending in part upon the time and temp. of vulcanization and upon the amt. of S. Mixts. contg. accelerators had a lower d. c. than similar mixts. contg. S only, and accelerated mixts. with low S in some cases had a d. c. not far different from that of I. Those factors which increase the amt. of S combining with I also increased the d. c. With 8% S it increased from 2.5 when unvulcanized to 3.0 at the optimum cure and then to 3.5 when overcured. With 4% S it increased to a max. of only 2.9. Though the d. c. depended on the state of cure and not on the time or temp. of the cure, it was not a simple function of the amt. of combined S, for the d. c. of hard rubber was lower than some compds. with 8% combined S. In general the elec. consts. of mixts. contg. fillers were intermediate between those of the filler and those of the rubber. Therefore all fillers increased the d. c., and C black increased both the d. c. and the p. f. greatly and lowered the r. value. Softeners had little effect. Data are given for various fillers. The min. values of the p. f. of I and of III were about the same, viz., 0.1%. In each case it was greater with a small amt. of moisture and with more it again decreased until at satn. it was again much the same as dry material. The p. f. of III increased with the resin content, com. III being about 1.5%. Vulcanization increased the p. f. of I, this increase depending on the amt. of S and the state of cure. Cured with 2% S and accelerated, it was about 0.3% and with 4-8% S and no accelerator about 0.4%. When overcured with 8% S it increased at times to 1-2%. Most fillers increased the p. f., C black greatly, 20% C giving a p. f. of 8%. The r. of I and III varied with the source and compn., the range being 10^{14} to 10^{16} ohm-cm. in each case. Neither vulcanization nor ordinary amts. of most compounding ingredients changed greatly the value of r. PbO in some amts. increased it by a factor of 10 and 35% C black decreased it to 10^8 . The law d. c. = n^2 was found to be valid when both detns. were made at the same frequency. Various types of I had almost an identical value, viz., n_D^{25} 1.619, which was not altered by prolonged washing, indicating that n is a function of the hydrocarbon and is little influenced by accessory ingredients. *Absorption of water by rubber.* I absorbed 5-40% at room temp. in 6 months, 10-20% being absorbed in the majority of cases. In no case did this absorption reach an equil. In salt soln. the absorption was much less and reached an equil. In 3% aq. NaCl the absorption was 1-3% in 1 month at room temp., after which there was no further increase. The addn. of ozocerite, palm oil, beeswax, vaseline, asphalt, etc., did not influence this absorption, and with fillers the absorption decreased in proportion to the decrease in rubber content. Absorption was less at technically correct cures than at under- or overcures. Addn. of H_2O -sol. substances greatly increased the absorption, and so the absorption was lower when well washed I was used. Sprayed latex I had the highest absorption and pale crepe the lowest among com. types. It was possible by washing I to limit the absorption of the vulcanizate in water to 1-2% and to prevent all absorption in 3% aq. NaCl. Immersion in water for 3 yrs. caused an increase in the d. c. of III and II (prep'd. from

the best I) about 10%, whereas vulcanizates from poor I increased over 30%. There were no marked changes in the p. f. or r. The results indicate in general that it is possible to manuf. rubber insulation which is superior to gutta-percha for submarine cables. C. C. DAVIS

A new practical method for determining the viscosity of highly viscous solutions (solution of rubber) by means of a metal screen of fine mesh. RUDOLF DITMAR. *Rev. gén. caoutchouc* No. 16, 8-9(1925).—See C. A. 19, 3193. C. C. DAVIS

Acid-resisting rubber lining. W. PAULSEN. *Apparatebau* 37, 338-9(1925).—As the amt. of mechanically held S increases in the vulcanized rubber its resistance decreases. Rubber from old trees is better than that from young trees. Brief directions for applying are given. J. H. MOORE

Testing of rubber adhesive plasters and insulating tapes. RUDOLF DITMAR. *Rev. gén. caoutchouc* No. 16, 18-20(1925).—Substantially the same as C. A. 19, 3386. C. C. DAVIS

Vulcanization with sulfur chloride vapor. J. PANEM. *Rev. gén. caoutchouc* No. 16, 11-2(1925).—Descriptive. C. C. DAVIS

The action of vulcone. Reversion. LUDWIG STOLL. *Gummi-Ztg.* 40, 676-8 (1925).—It is already known that when a rubber-S mixt. is vulcanized longer and longer, reversion of the stress-strain curve to a form approaching that of an earlier stage of vulcanization takes place. Expts show that this type of reversion also occurs in rubber mixts. vulcanized with certain org. accelerators. Mixts. of rubber 100, S 5, ZnO 5 and vulcone (cf. Luttringer, C. A. 19, 1792) 0.5-6.0 were vulcanized in a press for progressively increasing times at 3.2 atm. steam pressure and the stress-strain curves, hardness and swelling power in C_6H_6 detd. The time to attain the max. tensile strength became less with increase in accelerator and the greatest max. was 266 kg. per sq. cm. in 12 min. with 4 parts. The elongations at a given stress (203 kg. per sq. cm.) also increased with the accelerator, while the range of optimum cure became shorter as the amt. increased. Beyond this range the ultimate elongation decreased more and more rapidly with increase in accelerator. After the max. tensile strength was reached, at which point the ultimate elongation decreased greatly, reversion of the latter occurred simultaneously with a decrease in the tensile strength. The magnitude of this reversion increased with increase in the accelerator, so that with the higher amts. the stress-strain curves approached those of the earlier stages of vulcanization. The swelling power decreased as vulcanization proceeded until reversion ultimately occurred, the extent of this reversion increasing with increase in the accelerator. The permanent elongation passed through a max., the magnitude diminishing with increasing amts. of accelerator. The hardness reached a max. which was approx. the same for all amts. of accelerator, after which it decreased, reversion therefore taking place. Reversion could not be detected in various mixts. contg. diphenylguanidine. It is suggested that these data may be of value in the reclaiming problem and may also serve as a basis for a simple classification of accelerators. C. C. DAVIS

The partial coagulation of latex. A. D. LUTTRINGER. *Caoutchouc & gutta-percha* 22, 12,942-3(1925).—A review and discussion of the work of Edwardes (cf. C. A. 19, 3037). C. C. DAVIS

The alkali reclaiming process. W. E. STAFFORD. *India Rubber J.* 71, 59(1926).—Pure gum tubes were devulcanized by the customary alkali process to det. changes in the chem. characteristics. The Me_2CO -sol. resin content is not increased by the alk. treatment and may be decreased through sapon. The free S can be completely removed. The mineral content increases, perhaps because of the retention of NaOH. A change in the rubber component occurs, which is manifest by an increase from a small proportion sol. in $CHCl_3$ to about over $1/2$ the total rubber content. The combined S in the $CHCl_3$ -sol. portion of the reclaimed rubber is present in proportionately much smaller amt. than in the $CHCl_3$ -insol. portion, though it was not proved whether the $CHCl_3$ -sol. portion becomes sol. only after removal of combined S or whether combined S is removed only after the substance becomes sol. in $CHCl_3$. C. C. DAVIS

Organophile colloids (WHITBY) 2. Elasticity (SCHOB) 2.

Articles of vulcanized rubber. T. W. MILLER. U. S. 1,569,662, Jan. 12. In the manuf. of rubber articles, a plurality of stocks are formed, each contg. a different proportion of agents such as oxide, S and accelerator which in proper proportion would produce vulcanization under working conditions, but separately ineffective to produce vulcanization in the sep. stocks. Layers or plies of these stocks are then assembled and vulcanization is effected.

Attaching rubber to metals. A. B. MERRILL. U. S. 1,570,445, Jan. 19. In uniting metals such as Fe or steel with soft rubber, a thin bonding film of a relatively rapid-curing hard-rubber compn. is applied to the metal, and on this film there is superposed a layer of relatively slow-curing soft-rubber compn. and the materials are vulcanized together.

Insulating gloves and boots. ST. HELENS CABLE AND RUBBER CO., LTD., AND H. C. HARRISON Brit. 234,716, Nov. 27, 1924. Two layers of rubber of different color are used together so that when the outer layer is worn through the exposure of the inner layer gives warning that the article is no longer fit for use. The outer layer may be formed of raw rubber 30, "crimson antimony" 5, French chalk 5, accelerator $\frac{1}{2}$, wax 1 and asbestine $8\frac{1}{2}$ parts.

CHEMICAL ABSTRACTS

Vol. 20.

MARCH 20, 1926

No. 6

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Potentiometer for routine determinations. C. W. G. HETTERSCHIJ. *Chem. Weekblad* 23, 3-4(1926).—The app. devised for the use of lab. technicians has the advantage of cheapness, simplicity, direct p_H reading and sturdiness. The measuring range is p_H 3.5-8.5. A rheostat and a resistance unit for rough and fine regulation are arranged on both sides of the circular constant resistance unit, subdivided into equal manganin coils with 100 dials. Thus the p_H difference between 2 dials is 0.05. The accuracy can be further increased by taking the av. of 2 galvanometer readings.

MARY JACOBSEN

Remark on the articles of E. Mislowitz "A new potentiometer" and "A new double electrode in the form of a beaker." M. TRÉNEL. *Biochem. Z.* 161, 506-7 (1925); cf. *C. A.* 19, 370, 927; Mislowitz, *C. A.* 20, 773.—T. claims priority. Reply to M. Trénel. E. MISLOWITZER. *Ibid* 508-10.

W. D. LANGLEY

The quartz plane manometer, an improved quartz wire manometer. ERNST BRÜCHE. *Physik. Z.* 26, 717-9(1925).—Preliminary report. The Haber-Kirschbaum manometer (the damping of the amplitude of a quartz wire, freely swinging in a gas with unknown pressure, is used as a measure for that pressure) has been improved by the author. He uses as a vibrating system 2 thin quartz bands (0.8×0.1 mm.), 7.5 cm. long, carrying a quartz plate of 3×3 cm., 0.05 mm. thick; the latter serves as a damper and also contains a small iron core for the initial magnetic agitation. The vibrations are recorded by projecting on a screen the motion of a quartz pointer attached to the system. The time for one reading (about one min.) is considerably reduced; the frequency is lower, which makes the instrument more accurate and less subject to external influences. Because of the large damping plane, the influence of internal friction (η) of the gas is noticeable, resulting in a smaller accuracy for higher pressures; the following relation holds (μ = mol. weight, p = pressure, c a const., θ the measured "half value time"): $p\sqrt{\mu} = c(1/\theta - \theta_\infty)$, in which $\theta_\infty\eta$ is a const. The instrument has an accuracy of 2% and can be used for pressures between 0.001 and 0.02 mm. Hg in chemically active gases. One standardization is sufficient if μ and η are known.

B. J. C. VAN DER HOEVEN

Photoelectric radiation pyrometer. F. A. LINDEMANN AND T. C. KEELEY. *Proc. Phys. Soc. London* 38, 69-73(1925).—By means of 2 photoelec. cells with suitable color filters the energy radiated in 2 distinct spectral bands is compared. By combining the ascertained sensitivities of the 2 cells and their filters with the radiation law the black-body temp. of the radiator can be detd. The cells, contg. resp. K and Rb, are cross-connected with an electrometer and the movement of the optical wedges in front of each cell necessary to give equal currents in the cells (no electrometer deflection) is detd. A change in wedge position of 1 cm. corresponds to 160° at 2000° K., 300° at 3000° K. and 700° at 4000° K.

W. B. PLUMMER

Two new types of high vacuum gage. E. BOLTON KING. *Proc. Phys. Soc. London* 38, 80-4(1925).—One gage described is of the *decrement type*, the construction being almost entirely of SiO_2 but with some interior metal parts, the app. being so arranged that the vibration of the cross-piece may be continuously photographed on an ordinary plate, the rate of damping being thus detd. more conveniently than in the ordinary app., an added advantage being that any irregularities in the vibration are clearly shown by the record. The app. must of course be calibrated against known pressures. A modified type of *Pirani gage* is also described in which the usual metallic filament is replaced by a fine spiral glass capillary filled with Hg, the pressure being detd. as usual by the rate of heat loss from the elec. heated Hg filament to the const. temp. walls of the app. The sensitivity is the same as the usual type of Pirani gage, the special advantage being that no metal is in contact with the evacuated space under examn.

W. B. PLUMMER

Densimeters with a sliding scale. Modification of the lactodensimeter of Quevenne.

MARIO SETTIMI. *Ann. chim. applicata* **15**, 378-86(1925).—A densimeter of the hydrometer type is designed to avoid reference to tables to convert the d. of the prevailing temp. to that at another temp. The top of the stem is provided with a bar, of rectangular cross-section and enlarged at its top, which slides back and forth through a slot of similar cross-section in a metal cap fixed to the top of the stem. The section of this bar sliding in the cap is graduated for the range of temp. desired. The app. is otherwise of the usual type with its d. scale on the stem below. The bar is set at the temp. of the measurement. The temp. scale on the bar is not arithmetical and it must be derived from temp.-d. tables for the particular liquid. The sliding scale is best prepd. by converting the temp.-d. tables to graphical form, from which the units of the scale to be constructed may be more easily obtained and the precision obtainable more easily detd. When used as a *lactodensimeter*, a scale may be provided for skimmed milk and for whole milk on the opposite flat sides of the bar. It is shown that one scale for each of these is accurate enough for most work. The metal parts are of Ni. By having the sliding graduated scale of flexible cardboard there is enough pressure of its lower end against the walls within the stem to hold the bar immovable when the instrument is set. Such densimeters are also particularly useful for the *rapid detn. of the d. of alc.-H₂O mixts.*, in which case they are fairly precise for mixts. contg 50-75% alc. but should not be used for mixts. contg. less than 50% alc. The following approx. relations were also derived for the *cubic expansion of whole milk and of milk dild. to 20% strength with water*. Whole milk (d_{15} 1.031): 0° to 5° , $V_t = V_0(1 + 0.0001t)$, 5° to 10° , $V_t = V_0(0.9999 + 0.00012t)$; 10° to 30° , $V_t = V_0(0.9997 + 0.0001t + 0.000004t^2)$; 20% milk (d_{15} 1.024): 0° to 30° , $V_t = V_0(1.0001 + 0.00004t + 0.000004t^2)$.

C. C. DAVIS

Dewar flasks in physical chemistry laboratory exercises. A. C. GRUBB. *Ind. Eng. Chem.* **18**, 163(1926).—In detg. heats of neutralization a simple app. is made from a quart size Dewar flask provided with a thin-walled tube (that can be made from an old condenser jacket) placed in it. Acid and alkali are thus contained in two glass vessels with an easily breakable wall between them, and the temps. before and after the reaction are read from the one (Beckmann) thermometer.

W. C. EBAUGH

New distillation flasks. ARNO MÜLLER. *Chem.-Ztg.* **49**, 691(1925), 3 cuts.—In 1 flask the side-tube enters the neck and terminates in a constricted opening bent slightly downward. In the other flask a large arm is fused to the neck close to the body and is bent upward parallel to the neck, extending a short distance above it. A bulb is blown near the lower end of the arm, and in the top of the bulb is a horizontal partition on which beads are placed. The opening through the partition is a tube extending downward with the end curved upward. A side-tube similar to the one on the other flask is attached to the arm above the beads.

J. H. MOORE

The Bureau of Mines Orsat apparatus for gas analyses. A. C. FIELDNER, G. W. JONES and W. F. HOLBROOK. *Bur. of Mines, Tech. Paper* **320**, 18 pp.(1925).—The app. described and illustrated differs from the ordinary Orsat app., principally in the compensation for changes of temp. and pressure by means of an auxiliary compensating tube, included in the water jacket surrounding the buret. If C_2H_6 is detd., a Cu oxide tube, elec.-heated, replaces the Cu_2Cl_2 tube and the CO is detd. with the H_2 by combustion. The prepn. of absorbents, notes on operation, and combustion data of the commonly occurring gases, vapors and solids are shown.

W. H. BOYNTON

Measurement of humidity in closed spaces. J. ALFRED EWING, R. T. GLAZEBROOK and EZER GRIFFITHS. *Dept. Sci. Ind. Research, Food Investigation Board Special Report* No. **8**, 54 pp.(1925).—Account of a study of existing types of hygrometers, together with a description of novel methods and instruments designed to meet special requirements. Cannot be satisfactorily abstracted.

A. PAPINEAU-COUTURE

Compressed air economizer. M. BERGER. *Apparatebau* **38**, 3-4(1926); 1 cut.

J. H. MOORE

A new instrument for the measurement of the flow of compressed air or gases. ANON. *Z. komprimierte flüssige Gase* **24**, 137-8(1925).—A compressed gas flowmeter has been designed to measure the rate of flow of compressed gases through pipes. A definite, small fraction of the main gas stream is expanded to atm. conditions and is measured by the usual type of gas meter. The fraction expanded is made proportional to the gas flow through the main pipe. The const. proportionality is automatically maintained by utilizing the pressure drop across an orifice in the main pipe to actuate the expansion valve, and by putting a small orifice in the sample line before the valve. The app. was designed by the Askania-Werke, Berlin-Friedenau. No data as to operating ranges are given.

R. L. DODGE

Apparatus for the determination of active hydrogen in organic compounds. R. BINAGHI. *Ann. chim. applicata* **15**, 432-4(1925).—The app. is designed primarily for detg. the vol. of hydrocarbon evolved in the action of RMgX on certain compds. contg. H which can be substituted (Grignard). Essentially it is the buret of the app. devised by B. for CO₂ (*Rend. soc. chim. ital* **12** (1913)) attached to the Grignard app. (*Compt. rend.* **130**, 1322(1900); *Ann. phys. chim.* **24**, (1902)). The top of the latter has a 2-way valve and during the prepn. of RMgX it opens to H₂SO₄. When the original compd. and the RMgX are mixed, the valve is changed so that the gas passes directly on through another 2-way valve to the buret. The pressure in the latter is regulated by a leveling tube. When the evolution of gas ceases, the valve on the buret is closed and the gas is measured after the pressure is adjusted. A jacket around the buret maintains the temp. const. and condenses the ether vapor accompanying the gas. By means of the 2-way valve on the buret and the leveling tube, the gas may be driven out and the app. made ready for a new detn. Satd. aq. NaCl is used to fill the buret. With a Grignard flask of 150 cc. and a 200-cc buret not over 0.004 g.-mol of substance should be used. The app. is illustrated. C. C. DAVIS

An automatic pipet for measuring noxious fluids. E. VAN SOMERAN. *Ind. Chemist* **1**, 528(1925). E. G. R. ARDAGH

A hydrogen electrode for flowing liquids. A. H. W. ATEN AND P. J. H. VAN GINNEKEN. *Rec. trav. chim.* **44**, 1012-38(1925). (In English).—Recently A. and van G. described a H electrode (*Tijdschr. Alg. tech. Ver. Beelwoortelsuikerfabr. en Raff.* **5**, 89(1924-5)) suitable for use with flowing liquids by which the H-ion concn. of a soln. of varying concn. can be detd. This H electrode app. was used at a sugar factory at Bergen op Zoom in 1923-24 and in 1924-25 for detg. the OH-ion concn. in sugar juices. The H potential established itself very quickly and gave reproducible values. The electrometric detns. of the H-ion concn. is superior to the phenolphthalein or rosolic acid method. It is not adapted at present for use by plant workmen but it is valuable in the factory lab. The app. is illustrated and described. The detn. of the OH-ion concn. of sugar juices and the experiences of the 1924-25 campaign are described in detail. E. J. WITZEMANN

The accuracy of graduated measuring vessels. I. H. V. RENN. *Ind. Chemist* **1**, 515-8(1925).—The liter and milliliter are defined and discussed. The following are then dealt with: standard temp., choice of vessels, occurrence of after-changes in glass vessels and in detail the essentials of the standard flask. Two tables of figures are to be used in detg. the wt. of the substance *in vacuo*: one of corrections for temp. variation, the other for atm. pressure variations. The procedure of testing a flask in the Natl. Phys. Lab. at Teddington is carefully described. E. G. R. ARDAGH

The value of the Lehmann microelectrode. G. E. VLADIMIRO AND M. J. GALIVIALO. *Biochem. Z.* **160**, 101-4(1925); cf. *C. A.* **18**, 2.—With Lehmann's microelectrode good results were obtained in the detn. of p_{H} in CO₂-free solns. When CO₂ was present, the method compared favorably in exactness and speed with other methods. It is considered as being especially convenient for the detn. of p_{H} in gels and tissues. F. A. CAJORI

Mistakes in attaching stirrer arms to the shaft. BERTHOLD BLOCK. *Chem. App.* **13**, 16-7(1926); 6 cuts. J. H. MOORE

The Dickinson alchometer. E. A. VUILLEUMIER. *Ind. Eng. Chem.* **18**, 261(1926).—An illus. description of a portable instrument for detg. EtOH content. It consists of a small still, hollow glass beads of definite d., and a graduated cylinder in a compact case. From the amt. of water needed to make the beads float, the % of EtOH is obtained by the use of a table. W. H. BOYNTON

Modern grate feeder. M. BERGER. *Apparatebau* **38**, 4-8(1926); 2 cuts. J. H. MOORE

Laboratory revolving furnace. D. K. *Chem. App.* **13**, 3-4(1926); 2 cuts.—Exptl. furnaces, 3 to 8 m. long, for oil or gas firing, built by G. Polysius, Dessau. J. H. MOORE

The vapor pressure of metals (RODEBUSH, DIXON) **2**. The utilization of volcanic steam in Larderello (OKRASSA) **13**.

British Standard Specification for Cast Iron Filter Plates and Frames. Edited by British Engineering Standards Assoc., London: C. Lockwood. & Son. 37 pp.

HONNICKE, G.: *Handbuch zum Dampfess und Apparatebau*. Berlin: Julius Springer. 210 pp. G. M. **15**. Reviewed in *Chemistry and Industry* **44**, 1169(1925).

Induced oxidation. W. P. JORISSEN AND C. VAN DEN POL. *Rec. trav. chim.* 44, 805-9(1925). (In English.)—Mittra and Dhar (C. A. 19, 3531) report that NaNO_2 , $\text{K}_2\text{C}_2\text{O}_4$, Na_3AsO_3 , Ni(OH)_2 , etc., can be oxidized by air or O_2 at room temp. in the presence of Na_2SO_3 , which in its turn is itself oxidized. In connection with Ni(OH)_2 but 2 qual. results are described, while the results of Haber and Brann (*Z. physik. Chem.* 35, 84(1900)) and Reinders and Vles (C. A. 19, 2441) are not mentioned. J. and v. d. P. give data in full (cf. C. A. 19, 205), showing that Na_2SO_3 does not "induce" the oxidation of $\text{Na}_2\text{C}_2\text{O}_4$ and NaNO_2 solns. by air or O_2 under ordinary conditions. Na_2SO_3 does not "induce" the oxidation of Na_3AsO_3 solns. when the alky. passes a certain limit.

E. J. WITZEMANN

A modern theory of alchemy. A. J. HOPKINS. *Isis* 7, No. 21 (reprint) (1925).—The ancient philosopher believed that (1) matter is one; (2) nothing exists except as it is good; (3) all nature is striving towards improvement; and (4) all nature is living. Artisans at first made artificial products to simulate the natural, such as pearls and Tyrian purple; later they prepared alloys and learned how to bronze metals. "Artificially such alloys were transmuted into more noble ones." The new theory of alchemy assumes that the alchemist inherited the above ideas and emphasized the importance of color changes. "The alchemist, like the artist, stressed the changeable Aristotelian qualities where we stress weight and fixed qualities. He changed color; therefore, (according to his definition of gold) transmutation was effected." W. C. EBAUGH

A didactic representation of the elements. ARNALDO PUOTTI. *Gazz. chim. ital.* 55, 754-6(1925).—The periodic representations of the elements used in chem. teaching are not satisfactory. P. has adopted a modification of the spiral representation as a wall chart. E. J. WITZEMANN

"Glykose" or "Glucose," "Glykosid" or "Glucosid?" ERNST DEUSSEN. *Z. angew. Chem.* 37, 508(1924). Comments on the article of Dr. E. Deussen. C. OFFENHEIMER; B. HELFERICH; K. FREUDENBERG. *Ibid* 831-2. Reply. E. DEUSSEN. *Ibid* 832. The letter Y in chemical nomenclature. "Glykose" or "Glucose," "Baryum" or "Barium." K. DAMMANN. *Ibid* 38, 232-3(1925). "Glykose" or "Glucose?" G. BRUHNS. *Ibid* 38, 351. The letter Y in chemical nomenclature. THEODOR STECHE. *Ibid* 911-3.—Deussen argues for "Glykosid," etc., as philologically correct. O. would use these as class names but retain "Glucose," "Glucosid," etc., for the particular series of compds. H. and F. also favor retaining "Glucose." Dammann prefers "Glykose" and cites Beilstein and other works. B. finds "Glucose" ambiguous in industry and proposes to return to the old "Dextrose" or "Traubenzucker," "Lävulose" or "Fruchtzucker" and "Invertzucker" (their mixt.). S. would regard "Glucose" frankly as an artificial word, using it and "Fructose" in science and "Traubenzucker" and "Fruchtzucker" in industry. Other German spellings are discussed. A. M. P.

Search for element 93. I. Examination of crude manganese compounds and the isolation of element of atomic number 75. J. G. F. DRUCE. *Chem. News* 131, 273-7(1925).—Element 93, if it exists, should have properties similar to those of Mn and, therefore, would most probably be found assocd. with Mn. Other new elements in this family, Nos. 43 and 75, have recently been announced by Noddack and Tacke (C. A. 19, 3178), while a search by Bosanquet and Kelley (C. A. 19, 768) for new elements of the group by X-ray methods was unsuccessful. D. investigates the "impurities" in com. MnSO_4 by pptg. Mn, Fe, Al, Cr with NH_4OH and H_2S . The filtrate

was evapd. to dryness and Ca removed. The residue (0.075 g. from 100 g. sample) was a light brown oxide giving a white nitrate. This impure oxide was examd. by the X-ray method. Besides weak lines for Fe and Mn, strong $\text{CuK}\alpha$ and $\text{CuK}\beta$ lines were found and also lines at $\lambda = 1.43$ A. U. and $\lambda = 1.233$ A. U., which are the wavelengths of the $\text{L}\alpha$ and $\text{L}\beta$ lines for element 75, rhenium, as detd. by Berg and Tacke (*C. A.* 19, 3178). Besides these lines the line $\lambda = 1.125$ A. U. was found but no line corresponding to element 93 was observed. **II. Examination of crude divi-manganese.** F. H. LORING AND J. G. F. DRUCE. *Ibid* 337-8.—The yield of crude oxide of divi-manganese or rhenium (Re) or element 75 by the above methods was 0.075% from "pure" MnSO_4 ; 0.120% from "pure" MnCl_2 ; and 0.015% from crude MnO_2 . The hydroxide of Re is white and flocculent, gradually becoming darker. The oxide is not sol. in caustic alkalis in soln. and turns to a chocolate color with Na_2O_2 . Fused with caustic alkalis or Na_2O_2 it gave a bluish green product resembling Ni compds. This product is sol. in water, giving a deep green soln., possessing oxidizing properties and is decolorized by solns. of FeSO_4 , $\text{H}_2\text{C}_2\text{O}_4$, SO_2 and by CO_2 . The soln. of K divi-manganate is unstable and forms the hydrated oxide in the course of a day. The brown oxide is sol. in dil. HCl and in H_2SO_3 . The chloride in soln. gives gray-brown ppts. with $\text{K}_4\text{Fe}(\text{CN})_6$ and with $\text{K}_3\text{Fe}(\text{CN})_6$ but no ppt. with Na_2HPO_4 or $(\text{NH}_4)_2\text{C}_2\text{O}_4$. The salt on a Pt wire gives a bright green flame persisting for only a second. An equiv. weight detn. by reducing the higher oxide to the lower in H corresponds to the reduction of ReO_3 to ReO if Re is taken as 188. **III. Foreshadowing elements 75, 85, 87, 93.** F. H. LORING. *Ibid* 338-41.—This is a crit. examn. of the X-ray results in this and in abstracts following. It appears that the evidence for the elements 75 and 85 is good, while the evidence for elements 87 and 93 is only fair as yet. JAMES M. BELL

Eka-caesium. F. H. LORING AND J. G. F. DRUCE. *Chem. News* 131, 289(1925).—On one of the photographic films of the X-ray spectrum (above abstr.) a line was found at $\lambda = 1.032$ A. U. which is exactly between the theoretical La_1 and La_2 lines of element 87. The $\text{L}\beta$ line was not found. The spectrograph does not sep. the La_1 and La_2 lines. The intensity of the line was a little less than the La line of Re. It is believed that the evidence points to the eka-caesium of Mendelyeev. **II.** F. H. LORING. *Ibid* 371.—The film contg. the La line of element 87 was projected on a scale for accurate measurement. A new faint line at the position of $\text{L}\beta$ for the element was found. JAMES M. BELL

Eka-caesium and eka-iodine. F. H. LORING AND J. G. F. DRUCE. *Chem. News* 131, 305(1925).—Further X-ray expts. on the same crude oxide of Re gave again the La line of element 87 and also the faint lines $\lambda = 1.086$ A. U. and $\lambda = 0.895$ A. U. These seem to correspond with the radiation of element 85, eka-iodine. **II.** *Ibid* 321.—The line $\lambda = 0.895$ A. U. might also be associated with $\text{La}\alpha$ of the suspected element 93. Another line at $\lambda = 0.693$ A. U. was indistinct but is apparently the $\text{L}\beta$ line of element 93. JAMES M. BELL

The discovery of eka-manganeses. IDA TACKE. *Z. angew. Chem.* 38, 1157-60 (1925); cf. *C. A.* 19, 3178, 3391.—The phys. and chem. properties and the relative occurrence in the earth's crust of the elements of at. nos. 43 (*masurium*) and 75 (*rhenium*) were predicted from the periodic table. A mixt. of the oxides was obtained from Pt ores and columbites. They are easily sol. in NaOH, more difficultly in NH_4OH . A yellow melt, due to Na_2MaO_4 , is obtained on fusion with KNO_3 and NaOH. Pb, Ag and Hg form difficultly sol. salts. The highest oxide of rhenium sublimates at 400° and dissolves in H_2O to form a colorless soln. from which white needles may be crystd. H_2S darkens the solid oxide but causes no ppt. in aq. soln. D. S. VILARS

Qualitative relationship between the molecular weight of metals and their specific gravity in the liquid state. A. JOUNIAUX. *Bull. soc. chim* 37, 1534-6(1925).—If the mol. vol. V is plotted against temp. t the mol. is shown to be monoat. when d^2V/dt^2 is pos., and polyat. when neg. With Al, Na and Hg, the curve is nearly straight; the mol. is monoat. in the observed range of temp. G. CALINGAERT

Influence of temperature on the molecular weight of copper. A. JOUNIAUX. *Bull. soc. chim.* 37, 1525-33(1925).—The mol. wt. of Cu has been calcd. from existing data by use of Clapeyron's formula and Trouton's rule for temps. above 2000° abs., and by cryoscopy in Sn, Bi, Pb, Cd, Sb, Al, Mg, Ag, Fe and Co for lower temps. If mol. wts. are plotted vs., temps., the curve shows the mol. to be diat. below 400° abs., monoat. between 650° and 1356° abs. (m. p.). Polymerization occurs at higher temps. Near the b. p. the mol. contains 8 atoms. The figures obtained by cryoscopy in Ag are not consistent with those given by the other metals. G. CALINGAERT

Molecular and atomic volumes. VIII. The volume of metaheulandite. WILHELM BILTZ AND FRANZ SPECRT. *Z. anorg. allgem. Chem.* 150, 10-9(1926).—The

at. vol. of salts which have lost part or all of their H_2O of crystn. cannot always be detd. by weighing in a non-aqueous liquid, as these sometimes replace the H_2O of crystn. In this case Hg can be used and the same method can be applied to detg. the *at. vol.* of zeolites such as heulandite. If the material is finely ground, however, the apparent *d.* of the heulandite is sometimes 100% low, as a result of changes in surface tension which prevent the Hg from wetting it. In this case petroleum can be used, or the value obtained in Hg can be corrected by evacuating and measuring the *vol.* of air liberated. The value obtained is somewhat high, indicating the condensation of air in the material. If the H_2O has been partly driven off, as in metaheulandites, then petroleum cannot be used, since it takes the place of the H_2O and Hg must be employed. A series of expts. is described in which H_2O is driven off and the *d.* detd. at various states of dehydration in both Hg and petroleum. There is no change in *mol. vol.* as detd. in Hg until 3 mols. of H_2O have been removed, when it drops suddenly from about 280 to about 250. The authors conclude from this that zeolitic H_2O does not enter into the crystal lattice. With petroleum there is no sharp break but a gradual falling off in *mol. vol.* as H_2O is driven off. Up to 3 mols., change in H_2O content affects the *mol. vol.* considerably, but from 3 to 6 mols. there is no appreciable effect.

IX. Isomers of chromic chloride hydrate and chromous chloride hexahydrate. ERWIN BIRK AND WILHELM BILTZ. *Ibid* 20-5.—The *ds.* of the 3 isomers of $CrCl_3(H_2O)_6$ were detd. by weighing in petroleum, and gave *at. vol.* as follows: for the dark green salt $[CrCl_2(H_2O)_4]Cl \cdot 2H_2O$ 145.2; for the gray salt $[Cr(H_2O)_6]Cl_2$ 148.1; for the bright green salt $[CrCl(H_2O)_5]Cl_2 \cdot H_2O$ 151.4. The dark green salt is the most stable and the bright green the least stable of the 3, going over to the dark green salt even in the dry state. The gray salt liberates 2.7 cal. in going over to the dark green salt. From this, stability seems to increase with *d.*, which is in agreement with the behavior of org. isomers. The solid *chromous chloride hexahydrate* was prepd. by cooling a highly satd. soln. in absence of air and sepg. the crystals from the liquor under the same conditions. It has the formula $CrCl_2 \cdot 6H_2O$, *d.* = 1.783, *mol. vol.* = 129.6. The *hexammines* of the bromide and iodide of Cr^+ have the same *mol. vol.* as the hexammines of Cr^+ , but this is not true of the chlorides. Since the *mol. vol.* of $CrCl_2$ is 42.7, the *mol. vol.* of hydrate H_2O is 14.5, which is in good agreement with the value obtained with the dark green chromic salt 14.7. The formula of the Cr^+ salt is, therefore, probably $[CrCl_2(H_2O)_4] \cdot 2H_2O$. Similar ammoniacal derivs. exist, and have smaller *at. vol.* for NH_3 in the trivalent salts than in the corresponding derivs. of Cr^+ . H. STOERTZ

The crystal lattice of solid carbon dioxide. J. DE SMEDT AND W. H. KEESOM. *Z. Krist.* 62, 312-3(1926).—The general structure as detd. by Mark and Pohland (C. A. 19, 2892) is verified, but the distance C—O should be 1.05 Å. U. instead of 1.60 Å. U.

L. S. RAMSDELL

The crystal structure of hafnium. W. NOETHLING AND S. TOLKSDORF. *Z. Krist.* 62, 255-9(1925).—Hf is hexagonal, with the close packing at. arrangement. Unit cell dimensions are $a = 3.32$ Å. U. and $c = 5.46$ Å. U., $c/a = 1.64$. The structure of zirconium, as reported by Hull is confirmed.

L. S. RAMSDELL

The lattice of carborundum type I. H. OTT. *Z. Krist.* 62, 201-17(1926); cf. C. A. 19, 1212, 3393; 20, 130.—Trigonal SiC (Baumhauer type I) is rhombohedral, with $a = 3.095$ Å. U. (same as types II and III) and $c = 37.95$ Å. U. Unit cell contains 15 mols. C atoms are at 000 , $00^2/16$, $00^4/16$, $00^6/16$, $00^8/16$, $00^{10}/16$; 5 more with same arrangement shifted through $-1/3$, $1/3$, $1/3$, and the remaining 5 shifted through $1/3$, $-1/3$, $2/3$. The Si atoms are similarly arranged, except that they are moved through $00p$, where $p = 1/20$. The same tetrahedral arrangement is found as in the other types.

L. S. RAMSDELL

Laue photographs of crystallized benzene. B. BROOMÉ. *Z. Krist.* 62, 325 (1926).—Laue photographs confirm the previous work of B. (C. A. 17, 2069) on benzene by the powder method. The best plates gave values for $a:b:c = 1:0.769:0.724$.

L. S. RAMSDELL

Contribution to the kinetic theory of vaporization. II. S. C. BRADFORD. *Phil. Mag.* 50, 1147-58(1925); cf. C. A. 19, 592.—The vapor pressure of liquids is a function of *mol. attraction. vol.* and *motion only* and is expressed in *atms.* by $p = 81.84 (T\lambda / -$

$$A\phi)c^{-\frac{9.656SvA^{2/3}}{T\delta'\lambda^2}}$$
 in which T is *abs. temp.*, λ the ratio of velocity of mols. in the liquid to that in the gas; A is the actual aggregation of the mols. in the liquid, ϕ the *cp-vol.* of the liquid, S the surface tension; v the *vol.* of 1 g.-mol., and δ' the nearest distance of approach of the *mol. centers* in the liquid. The ratio λ is a function of *temp.* and *d.* only and the relation between these three variables is discussed and given for 18 liquids at different temps. The vapor pressures for the same liquids are calcd. by the

formula for widely differing temps. and remarkable agreement with exptl. value is found.
S. C. L.

The crystalline structure of hexachlorobenzene and hexabromobenzene. W. G. PLUMMER. *Phil. Mag.* **50**, 1214-20(1925).—The spacings for C_6Cl_6 were detd. by the powder method using a Shearer X-ray tube with a Cu anti-cathode. For 2 mols. per cell the dimensions of the cell are: $a = 8.10$; $b = 3.86$; $c = 16.68$ A. U. Centrosymmetry is indicated for the C_6Cl_6 mol. Perfect cleavage along one plane (001) and imperfect cleavage approx. parallel to the (102) plane are not improbable. Assuming the "diameter" of Br as 2.38 A. U. and replacing the Cl atoms by Br but otherwise retaining the same structure as for C_6Cl_6 gives graphically, $a = 8.50$ and $c = 17.6$ A. U., which agrees with the theoretically calcd. structure for C_6Br_6 . The b -axis is about 4.1 A. U. Little success attended efforts to make good powder photographs of C_6Br_6 , but some spacings were obtained proving the general correctness of the proposed structure.
S. C. L.

Crystal structure of barytes, celestine and anglesite. R. W. JAMES AND W. A. WOOD. *Proc. Roy. Soc. (London)* **109A**, 598-620(1925); *Mem. Proc. Manchester Lit. & Phil. Soc.* **69**, 39-51(1924).—"The structures of the isomorphous sulfates of Ba, Sr and Pb have been investigated and all are found to be very similar. The structure is based on a simple orthorhombic lattice having 4 mols. to the unit cell, and the space group is V_4^6 . The positions of the atoms in the structure have been detd. by a study of intensities. In calcg. the structure factors, the figures for the diffracting power of ions at different angles, calcd. by Hartree, have been employed with slight modifications. A comparison of the abs. intensity of reflection actually observed with that calcd. on the classical theory has been made. The observed intensity is in all cases lower than, although of the same order of magnitude as, the calcd. A possible reason for the structure which is common to a no. of crystals is discussed."
BRIAN MEAD

X-ray investigation of the constitution in the liquid and solid states of substances at low temperatures. W. H. KEESOM. *Proc. Fourth Intern. Congress of Refrigeration* **1**, 117-20a(1924).—Brief discussion of the importance and advantages of such X-ray investigations with an outline of the work done by K. and de Smedt (*C. A.* **16**, 4135; **17**, 2822) and of work at present under way or completed but as yet unpublished.
A. PAPINEAU-COUTURE

The bending of crystals. C. H. BOSANQUET. *Proc. Phys. Soc. London* **38**, 88-91(1925).—A rock-salt crystal of approx. dimensions $15 \times 5 \times 2$ mm. was bent after immersion in strong brine at $50-70^\circ$ and then used to reflect X-rays. The spectrum lines of Mo $K\alpha$ and $K\beta$ are arcs about twice as long as the specimen, indicating that the orientation of the lattice varies from one part of the crystal to another. No crystal gave any reflection which indicated a change in the lattice const. The conclusions are in agreement with the idea that the process of bending consists of the breaking down of the crystal into small units which slip along rhombododecahedral planes and in addn. turn through narrow angles. The slip behaves as if it consists of a no. of small perfect crystals embedded in a very viscous fluid, presumably amorphous NaCl.
GEORGE L. CLARK

The arrangement of the atoms in the tetragonal crystals of Hg_2Cl_2 , Hg_2Br_2 , Hg_2I_2 and the calculation of the optical double refraction of Hg_2Cl_2 . EGIH HYLLEAAS. *Physik. Z.* **26**, 811-4(1925).—With the use of the powd.-crystal method of X-ray analysis, a structure is obtained for the mercurous halides which agrees with that of Havighurst (*C. A.* **19**, 2763). On the assumption that the lattice points are occupied by singly charged ions Hg^+ and Cl^- and on the basis of Born's theory of crystal lattice optics, the double refraction of Hg_2Cl_2 is calcd. By a proper choice of the parameter which det. the position of the Cl^- ions on the c axis, formulas are obtained which represent the double refraction and dispersion accurately.
R. J. H.

Amorphous carbon and graphite. OTTO RUFF, GERHARD SCHMIDT AND WERNER OLBRICH. *Z. anorg. allgem. Chem.* **148**, 313-31(1925).—The opinions of other workers that only 2 forms of C, diamond and graphite, exist, are discussed. The authors believe that amorphous C is a sep. modification and base their claims on X-ray spectra, a no. of which are shown for various types of C, graphite and C-graphite mixts. They find that amorphous C exists as an independent form, combined with graphite by means of paracryst. intermediate forms. Only amorphous C is active or capable of being activated and this property is lost at high temp., the amorphous form slowly changing to graphite. The significance of röntgenographs and their variation with various forms of graphite is discussed in detail. The conditions of transformation of certain types of amorphous C into graphite are given, including effect of catalysts, temp. required, time of heating and sp. resistance of product. B

was the best catalyst, the graphite formed by it showing a sp. resistance of 178 ohms, equal to that of Acheson graphite. The temp. was 2500°. Al was next and good results were obtained with Fe and Mn. The effect of catalysts depends on the degree of disson. of their carbides. Oxidizing agents can be used to det. amt. of graphite in a mixt. of graphite in C, fuming HNO₃ at 80°. Fused Na₂SO₄ heated in atm. of N at 1100° oxidized C readily but also attacked graphite strongly. CaCl₂ soln. at 100° is satisfactory. Chromic acid was found to be most successful. Curves are given showing soly. of C—graphite mixt. in various solvents. Resistance figures are also given, most of the graphites produced showing sp. resistance around 500 ohms.

H. STOERTZ

Influence of strain on the Thomson effect. H. E. SMITH. *Proc. Phys. Soc. London* 38, 1-9(1925).—The influence of tension on the Thomson effect in wires has been investigated by Nettleton's method (*C. A.* 19, 1984). For pianoforte steel, charcoal iron, constantan and Ni, the Thomson coeff. numerically decreases with tension until the elastic limit is reached, after which it increases. With removal and restoration of tension a new definite cycle is followed. The Thomson effect in W, here measured for the first time, increases with tension and also follows a cycle. No change in the Thomson effect is noticed in brass or German silver. Heterogeneity was not present in the specimens investigated.

GEORGE L. CLARK

Changes in the states of aggregation and polymorphism. V. KARL SCHAUW AND WALTHER NAUMANN. *Z. anorg. allgem. Chem.* 148, 217-24(1925); cf. *C. A.* 19, 57.—The conception of anisotropic mols. in fresh melts or "space lattice fragments" (*C. A.* 16, 1528) has been extended to abnormal phenomena produced by vigorous and prolonged heating. Expts. with undercooled vapors, satd. solns. and melts of several tautomeric and polymorphic substances are in conformity with the hypothesis advanced.

H. R. MOORE

Compressibilities of gases. S. F. PICKERING. Bur. of Standards, *Miscellaneous Publ.* No. 71 (Nov. 21, 1925).—Graphs are given for computing the compressibilities of air, A, He, H, CH₄, Ne, N and O and for computing the vols. delivered from cylinders contg. A, He, H, N and O at high pressures.

E. J. C.

Demonstration of the kinetic properties of a gas jet. J. S. G. THOMAS. *Proc. Phys. Soc. London* 38, 92(1925).—Brief description of expts. with a ping-pong ball and a toy balloon to illustrate the Bernoullian property of a gas jet which has a central region of low pressure.

GEORGE L. CLARK

The viscosity of ammonia gas. R. S. EDWARDS AND B. WORSWICK. *Proc. Phys. Soc. London* 38, 16-23(1925).—The viscosity of NH₃ gas has been detd. at 3 different temps. by transpiring the gas through a capillary tube which had previously been calibrated with air. Sutherland's const. is found to be roughly 370, and the mean collisional area of the NH₃ mol. 0.633×10^{-18} sq. cm.

GEORGE L. CLARK

Affinity and reaction velocity in perfect gases and vapors. G. VAN LERBERGHE. *Bull. acad. sci. roy. Belg.* 11, 241-8(1925).—A math. discussion, equations being developed for the relative rate of evapn. and condensation of a vapor in the presence of its liquid in terms of the sp. affinity of the system.

W. B. PLUMMER

The cryoscopy of solutions of gas in various solvents. FELICE GARELLI. *Atti accad. Lincei* [6] 2, 120-4(1925).—The study of the cryoscopy of gaseous solns. (G. and Falcicola. *Atti accad. Lincei* 1904, I, 110; Falcicola, *C. A.* 4, 407) was continued. The detns. were made in the Beckmann cryoscope into the side of which a tube was sealed low down to bubble the gas through. The cryoscopic tube was hermetically sealed and the mixt. was agitated with an electromagnet and a metronome interrupter. C₂H₂ is sol. to the extent of 0.737 g. in 100 g. PhNMe₂ as simple mols.; 0.800 g. is sol. in 100 g. PhNH₂; 0.3107 g. is sol. in cyclohexane and 0.5537 g. in 100 g. PhNO₂. The f. p. of H₂O remains unchanged when NO is passed through after expelling the air with N₂. The lowerings of the f. p. for N and NO in C₆H₆, CHBr₃, PhNO₂ and cyclohexane were too small to be of much significance in detg. the soly., which in these cases appeared to vary from 0.02 to 0.06 g. per 100 g. of solvent. In PhNO₂, C₆H₆, CHBr₃, C₆H₁₂, AcOH and HCO₂H he does not produce any measurable lowering of the f. p. with the 1st 4 solvents and is, therefore, practically insol. With AcOH and HCO₂H the small lowering observed may have been due to moisture absorbed. CO is practically insol. in C₆H₆, PhNO₂ and CHBr₃.

E. J. WITZEMANN

The vapor pressure of metals; a new experimental method. W. H. RODEBUSH AND A. L. DIXON. *Phys. Rev.* 26, 851-8(1925).—A vessel contg. the liquid and surrounded by a furnace for maintaining a uniform temp. is connected by one tube C to manometer M and by another tube B to an intermittent pump. Outside the furnace tubes C and B are connected by a differential manometer D. Successive portions of

an inert gas are pumped off through *B* until the manometer *D* begins to show a small but permanent difference. The pressure at *M* is the vapor pressure desired. The principles of the method are discussed and exptl. procedure is described. The vapor pressure of *Pb* is detd. from 1118° to 1235°, the accuracy of the method having been demonstrated for *Hg*.
D. C. BARDWELL.

Mercury vapor pressure at low temperatures. F. E. POINDEXTER. *Phys. Rev.* **26**, 859-68(1925).—The vapor pressure of *Hg* was measured for 20° to -80° by a modified Buckley ionization gage, with a range from 10^{-2} to 4×10^{-9} mm. Correction was made for thermal effusion. The gage was calibrated at 0° from Knudsen's value. Heats of vaporization and fusion are calcd.
D. C. BARDWELL.

Kinetic theory of the viscosity of liquids. MITSUO SU SATO. *Sci. Repts. Tohoku Imp. Univ.* **14**, 403-44(1925).—Mathematical.
BRIAN MEAD.

Viscosity and chemical analogy, in relation to the viscosity of aqueous solutions of metallic acetates. L.-J. SIMON. *Compt. rend.* **181**, 862-4(1925).—Earlier investigations on viscometric neutralization (*C. A.* **18**, 2098, 2452; **19**, 1079, 2439) have been extended to include *N* *HCO₂H*, *CH₃CO₂H*, *C₂H₅CO₂H*, *CH₂ClCO₂H* and *CCl₃CO₂H* neutralized at 15° with *N* *NaOH* and *KOH*, as well as *N*, 0.5 *N* and 0.25 *N* solns of *CH₂ClCO₂Na* and acetates of *K*, *NH₄*, *Na*, *Li*, *Ba*, *Sr* and *Ca*.
EUGENE C. BINGHAM.

The change of viscosity with the rate of shear in disperse systems. A. DE WAELE. *Kolloid-Z.* **36**, 332-3(1925); cf. *C. A.* **19**, 2288.—The disappearance or diminution of "shortness" on agitation of flocculated systems, e. g., mineral earths in light petroleum, suggests an amendment to the original plastic-flow equation of the author (*C. A.* **18**, 3501) in order to show the progressive loss of "yield value" with shear, thus: $[g\pi R^4(P - f e^{-K})]/8Vt = \eta$, wherein *f* = the yield value of the system at rest (static yield value), *e* = log base, *K* = the stress applied = *PR/2l*, the other symbols having the significance of those in the earlier equation. The regain of yield value or "shortness" on rest after shear or deflocculation can be shown by substitution of η/t for the *PR/2l* exponent in the above equation.
A. DE W.

The p_H of water. A. KLING AND A. LASSIEUR. *Compt. rend.* **181**, 1062-4(1925).—*H₂O* was distd. in a completely enclosed Pt still, and the p_H detd. colorimetrically and the results were checked electrometrically. A single distn. gave *H₂O* with p_H 5.8, which is unaffected by the method and degree of purification used. The p_H does not change when this *H₂O* is allowed to stand in Pt or Jena-glass bottles, stoppered or not, in contact with an atm. of normal compn. If the acidity observed were due to the presence of *CO₂*, its concn. would be of the order of 0.00001 *N*. Admitting the presence of this concn. of *CO₂*, acidimetric titration with standard *Ba(OH)₂* requires 5-6 times the calcd. amt. of alkali. *K.* and *L.* conclude that, either *H₂O* has an acid reaction with p_H 5.8, which cannot be attributed to *CO₂*, or else present p_H detn. methods are erroneous, at least for highly purified *H₂O*.
A. PAPINEAU-COUTURE.

Precipitation. III. SVEN ODÉN. *Ark. Kem. Min. Geol.* **9**, No. 23(1925).—The formation of ppts. consists of the following stages: (1) Condensation of ions and mols. into more stable groups or unit-cells. The total no. of primarily formed nuclei is a function of the type $n = \text{const.} (C_1 C_2)^{\alpha}$ in which *n* is the no. of nuclei, *C₁* and *C₂* are the concns. of the reacting ions, α is a no. greater than 3 and dependent on the no. of ions in the unit-cell, and *t* the time. (2) The velocity of growth of these nuclei is $-dc/dt = [D/\delta] \cdot O_t(C_1 - C_{\infty})$ where *dc/dt* is the velocity of growth, *D* the coeff. of diffusion, δ the thickness of the layer of diffusion or adhesion, *O_t* the total surface of the primary particles, *C_t* the concn. at the time *t*, and *C_∞* the soly. concn. at the time ∞ . (3) The aggregation of the primary particles to secondary aggregates is analogous to the coagulation of colloids and may be summarized as follows: (a) With decreasing charge of the particles, owing to the ions in the system, a crit. point will be reached when the primary particles will aggregate. (b) Passing below this charge, there will be a greater no. of particles in the aggregate the smaller the charge of the individual particles, thus tending to form aggregates of unlimited size with a zero-charge of the particles. (c) In the reversible aggregate there is no amalgamation of the individual particles and probably no equalization of the charge on the particles. The aggregates retain a certain charge or p. d. towards the fluid. (d) The time required for the complete formation of these aggregates is great compared with the formation of nuclei and their growth and inversely proportional to the no. of primary particles per cc. if the electrolytes are present in the same amt., but decreasing rapidly with increasing concn. of the electrolytes, being less than one minute in most cases. (4) In the formation of irreversible aggregates of the primary particles (a) of a definite structure as in snow-flakes, *BaSO₄*, *TiCl* etc., or (b) spherulites such as *CaCO₃*, or (c) an irregular shape due to external influences, the layers of water covering their surfaces are broken through,

resulting in contact between crystal surfaces. (5) The growing of bigger crystals at the expense of smaller ones is due not only to the difference in soly. with size but also the variation in size. The more marked the latter, the more rapidly recrystn. takes place.

Freezing points. H. W. FOOTE AND GENEVA LEOPOLD. *Am. J. Sci.* **11**, 42-6 (1926).—A review and a discussion of the effect of dissolved air on the f. ps. of compds. and solns. F. p. should be defined as the temp. at which solid and liquid are in equil. when satd. with dry air at a pressure of 1 atm. The effect of dissolved air on the m. p. of org. compds. is usually greater than its effect on the m. p. of water. A list is given of f. ps., which are probably accurate within $\pm 0.05^\circ$. W. H. BOYNTON

Interfacial tension and emulsification. I. Effects of bases, salts, and acids upon the interfacial tension between aqueous sodium oleate solutions and benzene. II. Extremely small interfacial tensions produced by solutes. WM. D. HARKINS AND HENRIETTA ZOLLMAN. *J. Am. Chem. Soc.* **48**, 69-80 (1926).—The interfacial tension between phases of water and benzene has been detd. in the presence of different concns. of Na oleate alone, or with NaOH, NaCl or oleic acid in addn. If NaCl of 0.1 N concn. and 0.1 N NaOH are in the aq. phase, the tension has the remarkably low value of 0.04 dyne per cm. Similar results are obtained with 0.001 N Na oleate. CaCl₂ largely overcomes the effect of NaCl even though it is fifty times more dil. A calcn. of the area per mol. in the const. film of Na oleate gives about 47 A. U., when sodium oleate alone is present, but sodium chloride of the same concn. reduces the area to 40 A. U. When the interfacial tension was below 10 dynes per cm. the benzene emulsified easily in the aq. phase, while when below 1 dyne it appeared to emulsify spontaneously.

Influence of thin surface films on the evaporation of water. E. K. RIDGAL. *J. Phys. Chem.* **29**, 1585-8 (1925).—Contrary to the results of Hedestrand (*C. A.* **19**, 759) it is found that fatty acids spread on the surface of water reduce its speed of evapn. greatly. The expts. are made in an evacuated inverted U-tube, one limb of which is held at 25 or 35° and the other immersed in ice. The % reduction goes parallel with the rate of surface compression by the resp. fatty acids. The fallacy of Hedestrand's method is pointed out theoretically and the results are given in tables. J. T. S.

Superficial solutions—fluids of two dimensions. ANDRÉ MARCELIN. *Ann. phys.* **4**, 459-527 (1926).—The term "fluids of two dimensions" is justified by the analogies between three-dimensional fluids and surface films of materials, such as oleic acid, which spread spontaneously. Such films were studied exptly. by two types of balances in which the surface energy (equiv. to reduction of the surface tension of the water) was balanced by a torsion element acting on a floating barrier between the film and pure water, and by chronograph records of the motion of paper floats or talc. in cases where the forces were too low for direct measurement. Films of oleic acid were shown to be capable of spreading as far as 14 times the area previously considered the limit of homogeneity. Pressure, area and temp. are connected by an equation of the gas-law type; $ps = kT$. The relation between p and s is clearly shown by expts. of M.; variation with T was measured for one case by Delaplace. K depends on the substance, and is much less than R . When p is increased, reversible condensation to droplets occurs at a definite value (40 dynes/cm. for oleic acid); M. considers that the thickness of film at which this occurs represents a monomol. layer with contact. The value of 2.5 μ for the length of the oleic acid mol. obtained in this way agrees well with the results of X-ray detns. on the crystal. B. H. CARROLL

Negative adsorption. The surface tensions and activities of some aqueous salt solutions. A. K. GOARD. *J. Chem. Soc.* **127**, 2451-8 (1925).—"The neg. adsorption at the surface of aq. solns. of LiCl, NaCl, KCl, CdCl₂ and AgNO₃ has been detd. over wide ranges of concn., employing original surface tension detns. by the drop-weight method (*C. A.* **19**, 3405) and activity data from various sources. The results obtained are not in harmony with the supposition that the surface of these solns. consists of a single layer of oriented water mols., as has been supposed by Langmuir (*C. A.* **11**, 2849), since the mean thickness of the adsorbed layer varies with the concn. of the soln. and with the nature of the salt. Evidence is adduced which indicates that in concd. soln. of CdCl₂ and possibly of AgNO₃, the adsorption is detd. by undissoc. mols. as well as by ions."

The adsorption of ions on a mercury surface. W. A. PATRICK AND P. W. BACHMAN. *J. Phys. Chem.* **30**, 134-5 (1926).—Fine drops of Hg falling through a soln. of mercurous sulfate or acetate adsorb more Hg than anion. B. H. CARROLL

Activated charcoals and their adsorptive power. OTTO RUFF. *Z. angew. Chem.* **38**, 1164-9 (1925).—Data are given which show the greater adsorptive power of "ac-

tivated" charcoal towards phenol in soln. and the gases NH_3 , A and CO_2 , and a variety of org. compds. Analyses show that the difference is not due to ultimate compn. The apparent d. and surface development are considered important factors. Temps. much above 1000° cause a decrease in both d. and activity. Activation was produced by carbonization of a great variety of org. materials at about 1000° with and without the addition of an alkali or salt, or by heating in CO_2 . The C must be kept in a highly amorphous state. Graphite could not be activated. R. considers that groups of about 12 atoms of C act as units, having one atom each with a free valence, which effects the adsorption of the C mass.

C. G. KING

The adsorption of barium chloride by colloidal hydrous manganese dioxide in aqueous solution. VITALIUS CHLOPIN AND A. BALANDIN. *Z. anorg. allgem. Chem.* 149, 157-66(1925).—"In the adsorption of BaCl_2 from aq. soln. by hydrous MnO_2 a chem. reaction is involved in which 2 mols. of HCl are formed from 1 mol. of BaCl_2 ; that is, the reaction is subject to the law of mass action. A partial adsorption, in the narrow sense of the word, of HCl and probably also of BaCl_2 takes place, which for the concns. studied is proportional to the amt. of MnO_2 employed. These two processes go on together, the first predominating at higher concns. of the salt and the second at lower concns. The results obtained for the adsorption of BaCl_2 permit the enunciation of the following hypothesis concerning the enrichment of Ba in Ra content by its adsorption by hydrous MnO_2 . Because of the exceedingly small concn. of Ra its adsorption probably follows the rule for adsorption in the narrow sense, while for the much higher concn. of Ba the adsorption is conditioned primarily by a chem. reaction. The enrichment can, therefore, be regarded as a consequence of the differences in the consts. for these two processes."

F. L. BROWNE

The adsorption of gases by wood charcoal at pressures above one atmosphere. F. A. HENGLEIN AND M. GRZENKOWSKI. *Z. angew. Chem.* 38, 1186-8(1925).—A sample of a com. gas-adsorption charcoal was used in detg. the adsorption of NH_3 , SO_2 and Cl_2 . The isobars for NH_3 up to 6 atm. are of the ordinary type. At the higher pressures the isobars are flatter at the lower temps. At 30° , the amts. of NH_3 adsorbed per g. of charcoal are the same for the 2 isobars, 8.19 and 9.01 atm. This charcoal at 30° adsorbs a max. of 30% of its wt. of NH_3 . The isotherms and isobars for SO_2 are all of the ordinary type. At 25° and 3.35 atm., this charcoal adsorbed 62% of its wt. of SO_2 . An apparent chem. reaction between Cl_2 and the charcoal was observed. At 15° and 4 atm. the charcoal adsorbed 70% of its wt. of Cl_2 . A simple demonstration expt. [to show: (1) The effect of temp. and pressure on adsorption; and (2) the liquefaction and vaporization of a gas] is described.

J. H. PERRY

The mobility of the particles in gold hydrosols. P. A. THIESSEN AND J. HEUMANN. *Z. anorg. allgem. Chem.* 148, 382-90(1925).—In Au hydrosols prepd. by reduction the mobility of the particles in an elec. potential gradient was found to be independent of the degree of dispersion and of the method of prepn. and was not altered by dialysis for 1 week. The mobility was about 3×10^{-4} cm./sec. per v./cm. The addn. of protective colloids had no influence on the mobility. Addn. of electrolytes to the Au sols reduced the mobility and in some cases reversed the direction of migration. Na_2CO_3 added to a dialyzed Au sol increased the mobility of the particles markedly, indicating an important connection between hydroxyl ions and the charge on the Au particles.

F. L. BROWNE

The influence of electrolytes on the life period of dispersoid solutions of sulfur prepared by mechanical methods. P. P. v. VEIMARN AND S. UTZINO. *Mem. Coll. Sci. Kyoto Imp. Univ.* 8, 291-306(1925); cf. *C. A.* 19, 2585. (In German.)—The exptly. established 2nd max. in the life curve of dispersoid solns. of S under the influence of the KCNS and $\text{Ca}(\text{CNS})_2$ present adequately supports the theory that adsorption and chem. forces are essentially identical. The fact that the life curves for dispersoid cellulose solns. in H_2O with progressive increasing concns. of salts are identical in form (not only qual. but almost quant.) with the life curves of dispersoid S solns. under the same conditions is sufficient to indicate the very general application of the theory.

H. M. McLAUGHLIN

The influence of substances added on the life period of dispersoids. I. P. P. v. VEIMARN. *Kolloid-Z.* 37, 151-8(1925); cf. *C. A.* 19, 2585.—A theoretical discussion preliminary to a series of articles is given. The life period of dispersoid solns. is considered to be a function of many variables. Elec. energy is only 1 of these and elec. charges of themselves exclusively cannot regulate the life period of dispersoid systems. The variables include all possible transformations of atoms of the disperse phase with the disperse medium and all that it contains. Probably no completely free ions exist and what is adsorbed by the disperse particles is not free individual ions but strongly

solvated mols. with greatly weakened bonds between the individual atoms and atom groups. The difference between adsorption and chem. forces is only in the intensity. A dispersoid soln. can be destroyed by (1) complete soln. of the particles of the disperse phase, (2) flocculation and deposition as micro- or macro-aggregates, (3) soln. of the particles of the disperse phase and deposition of other particles. Added substances may increase or decrease or have no effect on the life period or the same substance may produce each of these effects at different concns. In the sense of the theory coagulation is nothing but a shortening of the life of a dispersoid soln. to such a small period of time as we have agreed upon.

H. M. McLAUGHLIN

Determination of the size of colloidal particles by means of alternating electric fields. E. F. BURTON AND MISS B. M. REID. *Phil. Mag.* 50, 1221-6(1925).—For particles below a certain crit. size Brownian movement completely masks gravity and prevents settling. If an alternating elec. field be applied to a vertical colloidal soln. so that direction of migration is for alternate periods with and opposed to gravity, the rate of settling shows a difference which may be used to relate the size of the particle with the velocity. The final formula is $a^2 = (9/2) \eta \nu / (\rho - \rho') g$, in which a is the particle radius, η the coeff. of viscosity of water, ρ and ρ' are the ds. of particle and medium, resp., and g is the force of gravity. The method was applied to a Cu colloid to which addnl. amts. of electrolyte (KOH) were successively added. Velocity of settling increased from 0.89×10^{-5} to 1.29×10^{-5} cm./sec. from a neutral soln. to one contg. 24 drops of 0.01 N KOH in 200 cc. of colloidal soln. The calcd. diam. of particle rose from 7.14×10^{-6} to 8.60×10^{-6} cm.

S. C. L.

The stability of colloidal solutions. IV. The antagonistic action of electrolytes on concentrated and dilute sols and a general theory of ion antagonism. K. C. SEN. *Z. anorg. allgem. Chem.* 149, 139-49(1925); cf. *C. A.* 19, 2291.—"Mixts. such as $\text{FeCl}_3 + \text{KCl}$, $\text{Al}(\text{NO}_3)_3 + \text{K}_2\text{SO}_4$, etc., exert a marked antagonistic effect in the coagulation of pos. Fe_2O_3 hydrosol. The same relation was observed toward As_2S_3 sol with the salt pair $\text{K}_4\text{Fe}(\text{CN})_6 + \text{KCl}$. This effect can be obtained with practically all colloids by choosing suitable salt pairs. With As_2S_3 the antagonistic action is more pronounced for dil. sols than for concd. The abnormal relation between the diln. of this sol and the pptg. power of certain univalent ions is due to the great stabilizing action of ions of the same charge as the colloid. Ion antagonism in two-phase systems in general is explained as follows: If any ion of the same charge as that of the colloid is strongly adsorbed, or becomes concd. at the interface through increased concn. of electrolytes, there is a tendency for the charge and the dispersity to increase, opposing the action of any oppositely charged, coagulating ion which is already present or is added later. If on the other hand the oppositely charged ion is adsorbed the more strongly, there results either coagulation, discharge, or in the case of emulsions a reversal of phase. The equil. finally attained depends therefore upon an equalization between the anions on the one hand and the cations on the other."

F. L. BROWNE

Colloidal rhodium. A. GUTBIER AND EDITH LEUTHEUSSER. *Z. anorg. allgem. Chem.* 149, 181-90(1925).—*Prepn. of pure Rh*—The finely divided com. metal was heated in H_2 , then mixed with twice its wt. of NaCl and heated in dry Cl_2 until melted. On cooling it was powd. and remelted in Cl_2 . The Na_3RhCl_6 so produced was dissolved in H_2O to a concd. soln., sepd. from unattacked metal, and the soln. satd. with HCl gas. The NaCl (contg. some Rh) pptd. was filtered off by means of glass wool and used in further treatments of the com. metal. The filtrate was evapd. to dryness and redissolved in a little H_2O contg. HCl. Excess NH_4OH was then added and the soln. evapd. on the water bath with NH_4OH several times. It was finally brought nearly to dryness, treated with concd. HCl, and kept at the temp. of the water bath several hrs. The residue was washed, dissolved in hot water, and filtered into cooled, concd. HCl to ppt. $\text{Rh}(\text{NH}_3)_5\text{Cl}_3$. This was dissolved and pptd. several times. It was then converted to Rh either by reduction of the aq. soln. with $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ or by heating in H_2 . Pure $\text{Na}_3\text{RhCl}_6 \cdot 12\text{H}_2\text{O}$ was then prepd. as the starting material for making the colloid. Colloidal Rh prepd. by reduction is unstable, coagulating completely in less than 24 hrs. A stable colloid can be made by adding 2 parts of a 1% soln. of the aq. ext. of gum arabic to 1 part of 1% Na_3RhCl_6 , heating to 90° , and reducing with an excess of a soln. of $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ of a concn. between 1:1000 and 1:10, cooling and dialyzing until no more Cl passes into the dialyzate. The stability of the colloid is not increased by using solns. of Rh salt of less concn. The $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ must be added all at once because as soon as some colloidal Rh has formed $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ subsequently added is decomposed catalytically before it has time to react with the rest of the Rh salt. The dark brown colloid is stable for months. It still contains a large amt. of Cl. It is negatively charged and requires comparatively large amts. of electrolytes for its coagu-

lation. Heating to boiling for a short time does not affect it, but prolonged heating reduces its stability. Reversible solid preps. can be made by concn. over H_2SO_4 under reduced pressure.

F. L. BROWNE

Colloidal bismuth. A. GUTHIER, THEO. KAUTER AND ROLF GENTNER. *Z. anorg. allgem. Chem.* **149**, 167-80(1925); cf. *C. A.* **19**, 3192.—Colloidal Bi was made by adding to $\text{Bi}(\text{NO}_3)_3$ soln. glycerol and NaOH and then reducing with HCHO at 90° . The sol was very unstable. Stable colloids were made by adding a protecting colloid to the soln. before reduction. These Bi sols were purified by dialysis. The sols on evapn. to dryness gave a powder contg. 8 to 34% Bi which dissolved in water again very readily. Suitable protective colloids are the water exts. of agar-agar, *semex psyllii* and gum arabic. The colloidal Bi oxidizes again on contact with air rather readily.

F. L. BROWNE

Colloidal tellurium. A. GUTHIER AND BERTA OTTENSTEIN. *Z. anorg. allgem. Chem.* **149**, 223-9(1925).—A soln. of 1 g. H_2TeO_3 in 500 cc. H_2O was mixed with 2.6 g. of dextrose dissolved in a little H_2O , made alk. with NH_4OH , and concd. on the water bath to a sirup. As the evapn. continued, H_2O and NH_4OH were added from time to time. On dilg. finally to 100 cc. a dark brown colloid resulted which was purified by dialysis. The sol was exceedingly stable, neg. charged, and was frozen and remelted without change.

F. L. BROWNE

Studies on barium dithionate and the solubility of calcium dithionate. FUSAO ISHIKAWA AND GEN KIMURA. *Bull. Inst. Phys. Chem. Research* **5**, 1-16(1926).—Soly. of Ba and Ca dithionates is measured and the dehydration and the thermal decompn. of BaS_2O_6 are studied. Soly. and the sp. gr. of the soln. of BaS_2O_6 are as follows: 7.75 g. of BaS_2O_6 in 100 g. of the soln. at 0° , d_4^{20} 1.0702; 11.56 g. at 10° , d_4^{10} 1.1049; 15.63 g. at 20° , d_4^{20} 1.1430; 19.70 g. at 30° , d_4^{30} 1.1839; 23.55 g. at 40° , d_4^{40} 1.2207; 26.91 g. at 50° , d_4^{50} 1.2560; 30.13 g. at 60° , d_4^{60} 1.291; 33.08 g. at 70° , d_4^{70} 1.324; 35.69 g. at 80° , d_4^{80} 1.355; and 38.42 g. at 90° , d_4^{90} 1.387. The solid phase coexistent with each soln. is $\text{BaS}_2\text{O}_6 \cdot 2\text{H}_2\text{O}$. 2.24 g. BaS_2O_6 in 100 g. of the soln. causes the lowering of f. p. by 0.240° , 3.98 g. by 0.340° , 5.70 g. by 0.480° and 7.55 g. by 0.640° , which is the cryohydric point of the soln. Soly. of CaS_2O_6 and the sp. gr. of the solns.: 13.86 g. of CaS_2O_6 in 100 g. of the soln. at 0° , d_4^{20} 1.1213; 17.20 g. at 10° , d_4^{10} 1.1505; 20.18 g. at 20° , d_4^{20} 1.1772; 23.12 g. at 30° , d_4^{30} 1.2015; 25.80 g. at 40° , d_4^{40} 1.2248; 28.48 g. at 50° , d_4^{50} 1.2470; 30.94 g. at 60° , d_4^{60} 1.2684; 33.14 g. at 70° , d_4^{70} 1.2900; 35.91 g. at 80° , d_4^{80} 1.3116 and 38.04 g. at 90° , d_4^{90} 1.3338. The solid phase in each soln. is $\text{CaS}_2\text{O}_6 \cdot 4\text{H}_2\text{O}$. 2.04 g. of CaS_2O_6 in 100 g. of the soln. lowers the f. p. by 0.32° , 5.84 g. by 0.85° , 9.00 g. by 1.38° , 9.23 g. by 1.41° and 13.40 g. by 2.09° , which is the cryohydric point of the soln. The dehydration of $\text{BaS}_2\text{O}_6 \cdot 2\text{H}_2\text{O}$ has been examd. at different temps., it is changed into BaS_2O_6 without producing $\text{BaS}_2\text{O}_6 \cdot \text{H}_2\text{O}$. When the crystal is kept over P_2O_5 at $18-23^\circ$, 99.96% of the dehydration is observed in 79 days and 100.00% in 83 days. When the dehydration is conducted at 50° , 99.02% of the water is lost at 276 hrs and 99.95% at 291 hrs. At 90° , the dehydration is completed by a few hrs., but in this case a very minute amt. of BaS_2O_6 is decompd. into BaSO_4 ; at lower temp. almost no decompn. occurs, unless the dehydrated substance is kept for long time at the temp. The decompn. of BaS_2O_6 by heat is irreversible, producing $\text{BaSO}_4 + \text{SO}_2$. It goes quickly at first, but slowly at the end.

Solubility influences. I. The effect of some salts, sugars and temperature on the solubility of ethyl acetate in water. SAMUEL GLASSTONE AND ALBERT POUND. *J. Chem. Soc.* **127**, 2660-7(1925).—The soly. of AcOEt in aq. solns. of various concns. of chlorides, bromides and iodides of all the alkali metals and NH_4 , and in solns. of dextrose, levulose, sucrose and lactose has been detd. at 25° and 50° . The results may be expressed by the formula, $\log w = km/w + a$, where m = no. of g. mols. salt, and w = no. g. mols. water per g. mol. AcOEt and k and a are consts. for a given salt. In g. AcOEt per 100 g. pure H_2O the soly. is at 0° , 10.40; at 10° , 8.96; at 25° , 7.39; at 37° , 6.65; at 50° , 6.04. From the soly. results the degrees of hydration of the salts in soln. are calcd. and shown to agree with the values of previous investigators. The hydrations of the salts at infinite diln. are found by extrapolation. Non-electrolytes, such as sugars, reduce the soly. of AcOEt in H_2O . The paper is one of a series on the "salting out" effect and the results are discussed from this standpoint.

R. E. G.

Solubility of barium propionate. H. J. WING AND T. J. THOMPSON. *J. Am. Chem. Soc.* **48**, 104-6(1926).—Over the whole range of temps., 0° to 100° , the solid phase is the monohydrate. The soly. is as follows: at 0.3° , 36.5 in 100 g. soln.; 5.1° , 36.2; 15.0° , 36.0; 24.8° , 36.2; 34.8° , 36.2; 34.8° , 36.2; 34.8° , 36.6; 44.8° , 37.1; 55.0° , 38.0; 65.3° ,

38.9; 75.6°, 39.8; 80.4°, 40.2; 85.6°, 41.2; 90.5°, 42.2; 95.4°, 43.2; 100.7°, 44.7.

JAMES M. BELL

Solubility relations of isomeric organic compounds. VI. The solubility of the nitroanilines in various liquids. A. R. COLLETT AND JOHN JOHNSTON. *J. Phys. Chem.* **30**, 70-82(1926).—Solubilities of the 3 isomers in EtOH, C_6H_6 , $CHCl_3$, CCl_4 , Et_2O , $EtOAc$ and Me_2CO were detd. nearly to the m. p. by the synthetic method, with improved technic; the analytical method was used for check detns. and for water and 95% EtOH at 25° and 40°. The relative soly. in the liquids is generally, but not entirely the same for the 3 isomers; soly. in the liquids used was generally greater than the ideal value. CCl_4 is best for sepn. of ortho and meta.

B. H. CARROLL

The chemistry of gold. VICTOR LENHER AND C. H. KAO. *J. Phys. Chem.* **30**, 126-9(1926).— $HgAuCl_4$ may be extd. from aq. solns. by a large no. of aliphatic esters. The best results are obtained with $EtOAc$ from solns. contg. 10% HCl . By this method, Au may be quant. sepd. from the chlorides of Na, K, Mg, Ba, Fe, Al, Sr, Ca, Cr, Mn, Co, Ni, Zn, Hg, Cu, Cd, Pb, Bi, Sb, Sn and from H_2AsO_4 .

B. H. CARROLL

The activity coefficient of lithium hydroxide in water and in aqueous lithium chloride solutions, and the dissociation of water in lithium chloride solutions. H. S. HARNED AND F. E. SWINDELLS. *J. Am. Chem. Soc.* **48**, 126-35(1926).—From measurements on the cells $H_2 | LiOH(m_2) | Li_2Hg | LiOH(m_1) | H_2$; $H_2 | LiOH(m_2), LiCl(m) | Li_2Hg | LiOH(m_1) | H_2$; and $H_2 | HCl(m_0), LiCl(m) | AgCl | Ag$, H. calcs. the activity coeff. of $LiOH$ in aq. and $LiCl$ soln., of HCl in $LiCl$ soln., and the ionic activity coeff. of water in $LiCl$ solns., by methods described in *C. A.* **19**, 1365, 1802. The activity of $LiOH$ is less than that of $NaOH$ or KOH at the same concn., and $LiCl$ in high concn. increases the dissocn. of water by more than $NaCl$ or KCl .

B. H. CARROLL

The osmotic pressure of aqueous solutions of cerous chloride. ALFREDO CHISTONI. *Arch. farm. sper.* **40**, 161-3(1925).—Lowering of f. p. was detd. for various concns. of $CeCl_3$ soln. from 4.0 to 0.5%. The concn. isotonic with 0.75% $NaCl$ is 2.57%. This value may be applied in biological expts.

A. W. DOX

Dissociation constants of organic molecular compounds. H. v. HALBAN AND E. ZIMPELMANN. *Z. physik. Chem.* **117**, 461-77(1925).—The photoelec. compensation method developed by H. and Siedentopf (*C. A.* **16**, 2078) is used to est. the extinction coeffs. of org. compds. at various concns. Degree of dissocn. is given by the equations $E_1 = \epsilon c_1(1 - \alpha_1)$ and $E_2 = \epsilon c_2(1 - \alpha_2)$, in which E_1 and E_2 are extinctions of solns. 1 mm thick of concns. c_1, c_2 , resp. Since light absorption is only slightly influenced by temp., the true equil. consts. are easily derived from these extinction measurements. The following mean values of K were obtained for λ 's in the neighborhood of 510 μ : acenaphthene-*s*-trinitrobenzene in $C_2H_2Cl_4$, 0.497; acenaphthene-*m*-dinitrobenzene in $C_2H_2Cl_4$, 3.51; acenaphthene-picric acid in $C_2H_2Cl_4$, 0.524; anthracene-picric acid in $CHCl_3$, 0.219. The mass-action law is obeyed for these substances to relatively high concns. From the values of the dissocn. consts. detd. at different temps., the heats of formation of the compds. are detd. with accuracy.

H. R. MOORE

The rate of reaction of bromine with aqueous formic acid. D. L. HAMMICK, WM K. HUTCHISON AND F. R. SNELL. *J. Chem. Soc.* **127**, 2715-20(1925).— $HCOOH$ is completely oxidized to H_2O and CO_2 in aq. soln. by Br_2 and the reaction is of the second order, but the rate is retarded by the HBr produced. The Ostwald isolation method was used. There was always excess of HBr in the reaction mixt. It is shown that the rate of reaction is inversely proportional to the active concn. of H ion and that the retarding effect of the bromide ion is due to its tendency to remove free Br_2 as the complex ion Br_3 . From these 2 results it is deduced that the reaction takes place between the formyl ions and the Br_2 mols. The const. for the equil. between Br_2 , bromide ions and tribromide ions in aq. solns. of $HCOOH$ is given as 0.070, in terms of the ionic activities, as against 0.048 (recalc. in terms of activities) given by Jakowkin (*Z. physik. Chem.* **20**, 19(1896)) for aq. solns. of slightly higher Br concn.

R. E. G.

The unimolecularity of the inversion process. S. W. PENNYCUICK. *J. Am. Chem. Soc.* **48**, 6-19(1926).—The unimol. inversion coeff. has been detd. by the polarimetric method from the equation $dx/dt = k(\text{sucrose mols. per mol. } H_2O) (H \text{ activity})$. The steady increase in the coeffs. up to 4% is explained by the decrease in H_2O content and the increase in H activity (1-3%). Four concns. of HCl were used: 0.02 *N*, 0.099 *N*, 0.507 *N*, 0.905 *N*, while the concn. of sucrose was always 17.1%. The zero time readings were detd. experimentally.

E. R. SCHIERZ

Catalysis. C. A. COPMAN-NICORESTI. *Pharm. J.* **115**, 345-7(1925).—The researches of Langmuir, Bone and others are quoted to show that the action of a catalyst is that of "a separator of heat from the other elements in the reaction." S. WALDBOTT

Catalysis. C. F. BAYLEY. *Pharm. J.* **115**, 433-4(1925).—A criticism of C. A. Cofman-Nicoresti's paper (preceding abstract).

The toxicity of thiophene for nickel catalyzer; a new action of copper catalyzer. BENNOSUKE KUBOTA AND KIYOSHI YOSHIKAWA. *Japn. J. Chem.* **2**, 45-62(1925). (In French).—The toxicity of C_4H_4S was studied by detg. the amt. required to inhibit completely the action of the catalyst. From the results, which are tabulated and plotted, K. and Y. conclude that the activity is due to the formation of various Ni hydrides, of which there are at least 4, and probably more: $HNiHH$ (I), $HNiH$ (II), HNi_2H (III), HNi_3H (IV), HNi_4H , etc., down to inactive Ni. The activity decreases from I down to the last member of the series. I catalyzes hydrogenation of the C_6H_6 ring; II, though less active, can also catalyze hydrogenation of aromatic compds.; III catalyzes hydrogenation of double bonds and IV that of nitro compds. "Poisoning" by C_4H_4S is caused by the reaction $C_4H_4S + Ni + 3H_2 = C_4H_{10} + NiS$, from which K. and Y. calcd. the proportion of active Ni in the total reduced Ni obtained at different reduction temps. and found: 250° 0.5%, 350° 0.2%, 450° 0.1%, 550° 0.04%, 650° and over 0.00. The effect of the temp. of ignition of the Ni salt (previous to reduction) is not as great as had been thought, the max. being about 800°. Contrary to catalysis with Cu, variations in the rate of the current of H have but very little effect. Differences in the toxicity of various compds. is attributed to the fact that some of these compds. react with all the forms of active Ni while others act selectively only on the most active forms. C_4H_4S has no action on reduced Cu, which does not catalyze hydrogenation of the C_6H_6 ring. Cu catalyzes hydrogenation of *phorone* to *valerone*, showing that both the α and β double bonds are hydrogenated, whereas Sabatier and Senderens had obtained hydrogenation of the α double bond and doubted the possibility of hydrogenating the β bond (*Compt. rend.* **134**, 1127(1902)). The m. p. of *valerone semicarbazone* was found to be 121°, instead of 106-15° previously reported by Nef (*Ann.* **313**, 169(1901)) and by G. Ponzio (*Gazz. chim.* **35**, II, 365-9).

A. PAPINEAU-COUTURE

Selenium as a chlorine carrier. OSWALD SILBERRAD AND C. A. SILBERRAD. *J. Chem. Soc.* **127**, 2449-50(1925).—To reconcile the conclusion of Willgerodt (*J. prakt. Chem.* **31**, 539(1885); **34**, 264(1888)) that Se does not act as a Cl carrier in chlorination reactions and the work of S. S. and Parke (*C. A.* **19**, 3197) that Se is probably a Cl carrier with SO_2Cl_2 , Cl was passed into boiling PhMe with and without addn. of $SeCl_4$, in darkness and in light and the amts. of ClC_6H_4Me and $PhCH_2Cl$ were detd. The results show that contrary to Willgerodt, Se acts as a carrier in direct chlorination, and that its presence not only increases the ratio of nuclear to side-chain substitution, but also to a lesser extent increases the amt. of Cl combining in a given time. C. C. DAVIS

Catalytic decomposition of hydrogen peroxide in a bromine-bromide solution. III. The interpretation of rate measurements as a function of the activity product of hydrobromic acid. R. S. LIVINGSTON. *J. Am. Chem. Soc.* **48**, 53-8(1926); cf. *C. A.* **17**, 3442.—The steady-state rate of decompn. of H_2O_2 in a bromine-bromide soln. can be represented by an empirical equation of the following form for all solns., including those contg. sulfates, the ionic strength of which is less than unity: $-d[H_2O_2]/dt =$

$0.043[H_2O_2][\bar{H}][\bar{B}r]\gamma^2$. γ is the activity coeff. of HBr. The constancy of the steady-state function for this catalytic reaction can be greatly improved by substituting activities for concns. of all electrolytes involved. The av. value of the steady-state function so converted is 1.7. J. M. B.

Dehydrogenation of methanol and formaldehyde with copper as catalyst. A study of the conditions of the equilibrium in the system: $HCHO \rightleftharpoons CO + H_2$. J. C. GHOSH AND J. N. CHAKRAVARTY. *Quart. J. Indian Chem. Soc.* **2**, 142-9(1925).—The equil. of the reaction $CH_3OH \rightleftharpoons HCHO + H_2$ (I) and $HCHO \rightleftharpoons CO + H_2$ (II) were detd. by a static method, with Cu-pumice catalyst. For I the value found for K_p at 155° was 0.37 and at 205°, 0.65; these values differ widely from those calcd. by a Nernst-type equation. For II the values of K_p from 155° to 340° (ranging from 0.032 to 2.20) were represented fairly well by the equation: $\log_{10} K_p = -(11,800/4.571T) + 1.75 \log_{10} T - 0.001T + 0.3$. DONALD W. MACARDLE

Catalytic formation of methane from carbon monoxide and hydrogen. I. K. M. CHAKRAVARTY AND J. C. GHOSH. *Quart. J. Indian Chem. Soc.* **2**, 150-6(1925).—A sugar-charcoal-Ni catalyst for the reaction $CO + 3H_2 \rightarrow CH_4 + H_2O$ retained its activity undiminished for months when the ratio of H_2 to CO was 3:1. The crit. space velocity (cc. gas mixt./cc. catalyst/min.) below which CO disappeared was fairly great (1.3 at 300°, 1.7 at 335°, 3.6 at 358°, >4.3 at 400°). This catalyst entirely suppressed the reaction $2CO \rightarrow C + CO_2$ and prevented deposition of C on the Ni

surface. CeO_2 acted as a promoter for this catalyst (cf. Medsforth, *C. A.* 17, 3271), increasing the crit. space velocity at 355° from 3.5 to 4.4. Some CO_2 (about 9 vol. % of exit gas) was produced, due mainly to the reaction $2\text{CO} + 2\text{H}_2 \rightarrow \text{CO}_2 + \text{CH}_4$ and partly to the reaction $\text{C} + 2\text{H}_2\text{O} \rightarrow \text{CO}_2 + 2\text{H}_2$. II. Production of fuel gases rich in methane. *Ibid* 157-64.—The use of a sugar-charcoal-pumice-Ni catalyst for the formation of CH_4 was studied with equimolar mixts. of H_2 and CO with view to its use in enriching blue water gas (H_2 49%, CO 42%). This catalyst was not as efficient as a sugar-charcoal-Ni catalyst (see above) for promoting the reaction $2\text{CO} + 2\text{H}_2 \rightarrow \text{CH}_4 + \text{CO}_2$ (I), and was little improved by addn. of CeO_2 . Pumice- V_2O_5 -Ni (A) was at first very effective, but rapidly lost its activity; as reaction I was retarded, the undesirable reaction $\text{CO} + 3\text{H}_2 \rightarrow \text{CH}_4 + \text{H}_2\text{O}$ (II) was favored, though with a smaller total conversion. A sugar-charcoal-pumice- V_2O_5 -Ni catalyst (B) at 400 – 50° retained for months the initial activity of A; increasing space velocity favored reactions II, but even with a space velocity of over 25 cc. gas/cc. catalyst/min. only 20% of the CH_4 was formed by reaction II. If sugar charcoal was replaced by coconut charcoal the catalyst deteriorated rapidly; Fe_2O_3 in place of V_2O_5 made II the chief reaction. The gas obtained by use of catalyst B was comparable in calorific value to carbureted water gas, though much less poisonous; removal of CO_2 (present in amts. as great as 33%) would give a gas of very high calorific value. DONALD W. MACARDLE

The decomposition of carbon monoxide in the corona due to alternating electric fields. I. MIGUEL CRESPI AND R. W. LUNT. *J. Chem. Soc.* 127, 2052-7 (1925).—Pure CO is prep'd. *in vacuo* from warm H_2SO_4 and H_2CO , freed from CO_2 by KOH and dried over P_2O_5 . This CO is exposed to a dark elec. discharge in an app. similar to the Siemens ozonizer. Single-phase a. c. of frequency 250 is used under 4500 or 9000 v. r.m.s., 1 or 2.5 milliamp. passing through the system. The mean temp. of the chamber is calcd. by an empirical formula from the electrode temps. The pressure is recorded and the time to reach sensible equil. The resulting gas mixt. is analyzed and always found to be close to 1 vol. CO_2 + 12 vols. CO , with varying small amts. of O_2 . A solid brown substance is deposited as described by others, which is hygroscopic. It consists of C and O in ratios varying from 1.2 to 1.4 with decreasing pressure.

JOHN T. STERN

A reversible reaction between an organic bromide and potassium iodide. ERIK HANNERZ. *Svensk Kem. Tids.* 37, 124-7 (1925). (In German).— $\text{MeCHBrCO}_2\text{H}$ and $\text{MeCHICO}_2\text{H}$ were treated with KI and KBr , resp., at 50° in aq. solns. KI was det'd. and plotted as concn. against time. When the Br was replaced the KI dropped from 1 mol. to 0.190 mol. and when I was replaced the KI increased from 0 to 0.195 mol. For equil. $K = 17.8$. A. R. ROSE

The forces between atoms and ions. J. E. LENNARD-JONES. *Proc. Roy. Soc. (London)* 109A, 584-97 (1925); cf. *C. A.* 19, 756, 757, 1093; 20, 319.—Extension of previous work on Ne and A to Kr - and Xe -like ions. Applications of the results are made to evaluate the interat. distances of a no. of crystals. In all, 32 crystals have been dealt with, including 16 alkali halides. For the latter, the calcd. values lie, with one exception, within 1 or 2% of the observed distances. Calcns. are also made of the compressibilities and crystal energies of these crystals; they are in satisfactory agreement with the values observed. BRIAN MEAD

Molecular combinations. J. MARTINET AND LOUIS BORNAND. *Rev. gen. sci.* 36, 569-77 (1925).—Mol. combinations are definite compds. produced by union of 2 or more mols., are essentially unstable and cannot be represented by ordinary valence structure. The mols. making such combinations are usually unsat'd. and may be classified as (1) auxochromes, or substances atomically unsat'd., such as $-\text{OH}$, $-\text{SH}$, $-\text{NH}_2$, etc., (2) chromophores, or substances constitutionally unsat'd., such as CO , CN , NO_2 , etc., and characterized by the presence of multiple valence bonds. M. and B. designate as "basoids" and "acidoids" those compds. that contain auxochromes and chromophores, resp. Examples of combinations with nitro acidoids, carbonyl acidoids, triphenylmethane and benzohydrol are given and discussed. The stability of combinations increases with the depth of color produced. The effect of various groups is discussed, for example, the nitro or carbonyl group introduced into a hydrocarbon, gives it an acidoid character while OH , CH_3O , or NH_2 increases the basoid tendencies. By classification of org. mols. into acidoids and basoids, polarity is admitted and a theory of their elec. attraction is developed. A bibliography is given. P. B. P.

(A) Isotherms of helium at 4.2°K. and lower. (B) Variation of density of liquid helium below its boiling point. H. KAMERLINGH ONNES AND J. D. A. BOKS. *Proc. Fourth Intern. Congress of Refrigeration* 1, 189-200a (1924); *Leiden Comm.* No. 170b.—

Isotherms of He were detd. at 4.21° , 3.72° , 3.40° and 2.57° K. The app. used is described in detail. The app. (special form dilatometer) and method of operation used in detg. the d of He are described. The following values are reported. 4.22° 0.1249, 3.90° 0.1305, 3.30° 0.1388, 2.56° 0.1451, 2.37° 0.1459, 2.30° 0.1462, 2.29° 0.1462, 2.21° 0.1459, 2.10° 0.1458, 1.93° 0.1455, 1.92° 0.1455, 1.59° 0.1453, 1.28° 0.1452, 1.20° 0.1452. A. PAPINEAU-COUTURE

Isotherms of helium from 20° to 259° . J. D. A. BOKS AND H. KAMERLINGH ONNES. *Proc. Fourth Intern. Congress of Refrigeration* 1, 81-7a(1924); *Leiden Comm. No. 170a*.—The procedure is described and the results obtained at $+20.00^\circ$, 0.00° , -37.40° , -70.32° , -103.64° , -142.01° , -183.32° , 201.51° , -225.01° , -235.91° , -249.87° , -252.63° , -256.04° and -258.78° are tabulated. A. PAPINEAU-COUTURE

Report on various researches on the isothermals and isometrics of oxygen, nitrogen and helium and the mixtures of nitrogen and oxygen. C. A. CROMMELIN. *Proc. Fourth Intern. Congress of Refrigeration* 1, 61-3a(1924).—Brief outline of the work carried out in the Leiden Cryogenic Lab. between the 3rd (1913) and 4th Intern. Congresses of Refrigeration on measurements regarding the equation of state of O, N, He and N-O mixts. A. PAPINEAU-COUTURE

Isotherms of oxygen at low temperatures. H. KAMERLINGH ONNES AND H. A. KUYPERS. *Proc. Fourth Intern. Congress of Refrigeration* 1, 65-7a(1924); *Leiden Comm. No. 169a*; cf. C. A. 18, 1219.—Isotherms are plotted for 20° , 0° , -40.05° , -80.03° , -102.46° , -109.97° , -113.97° , -116.01° , -116.99° . The results confirm the previously drawn inference that no chem. reaction occurs. A. P.-C

Isotherms of hydrogen from -217° to -240° at pressures up to 60 atmospheres. C. A. CROMMELIN AND J. C. SWALLOW. *Proc. Fourth Intern. Congress of Refrigeration* 1, 53-9a(1924).—Values obtained for θ , T , p , v_A , $p v_A$, d_A are tabulated and plotted and the results briefly annotated. A. PAPINEAU-COUTURE

The heat capacities of some metallic oxides. G. S. PARKS AND K. K. KELLEY. *J. Phys. Chem.* 30, 47-55(1926).—The heat capacities of MgO , CaO , Al_2O_3 , Fe_2O_3 and Fe_3O_4 were measured with an accuracy within 1% at temps between 87° and 295° K. by the method of Parks (C. A. 19, 1085). The view that a low heat capacity is a concomitant of exceptional hardness is borne out in the case of Al_2O_3 in the sapphire form. A finely divided and somewhat amorphous powder possesses a higher heat capacity than large crystals. A heat absorption occurs in magnetite between the temps. $113-7^\circ$ K. The neg. free energies of formation of the above oxides in the order named, at 298° K. are, resp., 137,000, 145,300, 356,300, 178,400 and 246,800 Cal. Their entropies at 298° K. are, resp., 6.6, 9.6, 12.8, 21.5 and 35.1 cal./degree. D. S. V.

The periodic flow of heat and the thermal stress in the wall of a long hollow cylinder. MICHIJIRO MAEKAWA. *Tech. Repts. Tôhoku Imp. Univ.* 5, No. 4, 1-24(1925). E. J. C

Remarks on W. Jaeger and H. V. Steinwehr's article entitled "The establishment of standard heat of combustion values." W. SWIENTOSLAWSKI. *J. chim. phys.* 22, 583-8(1925); cf. Jaeger and Steinwehr, C. A. 19, 1085.—A defence of the action of the international commission on a thermochem. standard in adopting Dickinson's value for the calorific value of $BzOH$. Fischer and Wrede's value for $BzOH$ is about 0.2% low; the $BzOH$ they used must have contained some unknown impurity. J. and S.'s detns. of the heat equiv. of Fisher's app. consistently show an error resulting in an increase of +0.3% in the calorific value detns. A. PAPINEAU-COUTURE

Report on the international temperature scale of low temperatures. W. H. KESSOM AND H. KAMERLINGH ONNES. *Leiden Comm. Suppl. No. 51* (In French); *Proc. Fourth Intern. Congress of Refrigeration* 1, 15-43a(1924).—The abs. thermodynamic or Kelvin scale, theoretical Avogadro scale, Avogadro scale for a definite gas, international Kelvin scale, international He thermometer scale, international correction table, Celsius scales and fundamental points are defined, and the reduction of the scales of the gas (H, He) thermometers to the international temp. scale is discussed. Essentially math. A. PAPINEAU-COUTURE

Vapor tension and heat of vaporization at low temperatures. J. F. VERSCHAFFELT. *Arch. néerland. sci.* [IIIA], 8, 109-35(1924); *Leiden Comm. Suppl. No. 49*; *Proc. Fourth Intern. Congress of Refrigeration* 1, 13-4a(1924).—It is generally taken for granted that at very low temps. the well-known equation of Clapeyron-Clausius takes the more simple form $d \log p/dT = \lambda/RT^2$, which may be considered as a limit relation between vapor tension and heat of vaporization near 0° abs. A 2nd thermodynamic equation, which is considered as a limit formula at low temps., is the relation $d\lambda/dT = C_2 - C_1$, between the heat of vaporization and the sp. heats of the vapor and of the condensed

state. Both relations are based on the assumptions that at very low temps the sp. vol. of the condensed state may be neglected against that of the vapor, and that the vapor behaves as a perfect gas. This last assumption, though probable, is still questionable. From the known variation of the sp. heat of the condensed state with temp. down to 0° abs., from the known exptl. values of the vapor tension and the heat of vaporization at temps. sufficiently low that the relations above are applicable with rather great approximation (e. g., at the triple point), and the theoretical value of the chem. const., the variation of the vapor tension and of the heat of vaporization of Hg, A, H and He was found by integration of the equations. For He the sp. heat of the condensed state may be considered practically = 0, and $\log_{10} p = -(3.1/T) + 2.5 \log_{10} T - 0.69$ (p in atm.), $\lambda = 14 + 5T$ (mol. heat).

A. PAINEAU-COUTURE

An application of spectrophotography to the measurement of high temperatures.

I. O. GRIFFITH *Proc. Phys. Soc. London* **38**, 85-7(1925).—The spectrum of the source is photographed through a neutral wedge placed immediately in front of a photographic plate. The curved boundary of the spectrum varies in height, the variation depending upon the distribution of energy in the source, i. e., upon its temp. It is assumed that the source radiates as a black body or a gray body, but with certain limitations the method is applicable to bodies which are neither black nor gray.

GEORGE L. CLARK

The measurement of temperatures by thermocouples in unequally heated enclosures. W. MANDELL. *Proc. Phys. Soc. London* **38**, 47-68(1925).—In measuring temp. by thermocouples in unequally heated enclosures the recorded temp. depends upon the thickness of the couple, the nature of the walls of the enclosure and the nature of the gas. An explanation is suggested based upon the fact that the amt. of radiation received and emitted by a couple depends upon its position in the enclosure, and that the amt. of energy transferred to it by mol. impact varies with the nature of the gas.

GEORGE L. CLARK

Thermal study of the paramagnetism of salts of cobalt in solution. CHATILLON. *Compt. rend.* **181**, 778-80(1925).—Sols. of CoCl_2 , CoSO_4 and $\text{Co}(\text{NO}_3)_2$ of varying concns. were studied at temps. ranging from 10° to 140° . The Curie point for these sols. was computed to be -12° . The results indicate that in every case the at. magnetic moment corresponds to 25 magnetons instead of to 24.5 as indicated by the results published by Trumplers and by Miss Brandt. The values were independent of the concn. The anhydrous sulfate gave -33° for the Curie point and 26 magnetons for the magnetic moment but on recrystg. and redissolving, the Curie point was found -10° with 25 magnetons. Apparently either form could be produced at will.

W. W. STIFLER

Specific heat variations in relation to the dynamic action of gases and their equation of state. WM. J. WALKER. *Phil. Mag.* **50**, 1244-60(1925).—Some preliminary expts. are first described relating to the detn. of the variable sp. heat function for highly superheated steam. It is emphasized that the neglect of any explicit incorporation of such a function in the thermodynamic equations for vapors obscures the reasons for many otherwise apparently anomalous results. The exptl. data so far obtained are few, because of difficulties encountered in the exptl. method, but they indicate the probable existence of an inflexion point on the const.-pressure sp. heat-temp. curve at the crit. temp. An analytical investigation into the problem of incorporating the variable sp.-heat function into the equations of state for gases and vapors occupies the latter portion of the paper. By a combination of fundamental thermodynamic relations with the most probable adiabatic relation for gases and vapors, as revealed by expt., an equation of the Dieterici-Jeans type has been derived, the qual. agreement of which with the behavior of gases and vapors in general appears to be good. By its form, the evidence also appears to be strong that the partial disagreement of this and other earlier types of equation with the phys. consts. of gases and vapors is due to the absence of any term in such equations directly involving sp. heat variations.

S. C. L.

Notes on the new law of mass action. I. Application of the new equations. RICHARD LORENZ. *Z. anorg. allgem. Chem.* **150**, 99-104(1925); cf. *C. A.* **19**, 3412.—The equation of the law of mass action for condensed systems contains the consts. r and r' , which as it is shown may be calcd. from the at. and mol. vols. of the compds. of the system at the temp. of the equil. Further it is shown that in the case of systems in which the initial and the reaction products contain the same no. of mols., the new form of the law of mass action results when the algebraic sum of the simple thermodynamic potentials of the individual phases of the equil. is considered as equal to 0; in systems where the no. of mols. of the initial and reaction product are different, e. g., $\text{Cd} + \text{Ti}_2\text{Cl}_2 \rightleftharpoons \text{CdCl}_2 + 2\text{Ti}$, the thermodynamic potentials are to be multiplied with the

no. of mols. in order to have the equations correspond with the general statement $\Sigma(\nu\mu) = 0$, where μ is the thermodynamic potential and ν the no. of mols. E. K.

Potential difference and equilibrium across a semipermeable collodion membrane in the case of sodium chloride and Congo red. KYOTARO AZUMA AND NAOTO KAMEYAMA. *Phil. Mag.* **50**, 1264-76(1925).—The potential differences and ionic equil. across a semipermeable collodion membrane in aq. solns. of NaCl and of NaCl plus Congo red have been measured. If Congo red in the range of concns. measured be assumed to ionize as a uni-univalent electrolyte, and if the ionic-strength principle of G. N. Lewis be assumed to hold good for the mixts. of Congo red and NaCl used, the exptl. results are in general agreement with the thermodynamical requirement of the equality of the activities of NaCl on either side of the membrane. Because of the difficulty of eliminating liquid-liquid potentials in solns. contg. Congo red, it has not been possible to prove that the potential difference across the membrane is in agreement with the thermodynamic requirement for a system in equil. S. C. L.

Behavior of nitrogen according to the law of corresponding states. A. TH. VAN URK. *Proc. Fourth Intern. Congress of Refrigeration* **1**, 79-80a(1924); *Leiden Comm. No. 169c*.—The investigation was carried out in the same manner as that of Kuypers on O (following abstract). The curves show a bend in the neighborhood of the crit. temp. and d. As the bend of the deviation curve displaces itself towards greater values of $\log \lambda_v$ with increasing temp., it is probable that the same bend exists also at higher temps., if measured at greater ds. The deviation curve of the points measured by Bridgman (*C. A.* **18**, 1219) cuts the zero axis with a pos. slope, while U.'s curves show that the slope at smaller ds. is neg. A. PAPINEAU-COUTURE

Behavior of oxygen according to the law of corresponding states. H. A. KUYPERS. *Proc. Fourth Intern. Congress of Refrigeration* **1**, 69-71a(1924); *Leiden Comm. No. 169b*.—By means of the equation of state in which the normal vol. has been taken a unit of vol. the pv_A -values of all isotherms have been calcd. for the ds. of all isotherm points measured. The differences of the measured and calcd. pv_A expressed in % of the latter are represented graphically. For the numerical results the *Leiden Comm.* should be consulted. A. PAPINEAU-COUTURE

Dielectric constants of liquids. I. Method of measuring dielectric constants of liquids. TOSHIKATSU MATSUIKE. *Sci. Repts. Tohoku Imp. Univ.* **14**, 445-52(1925).—An app. for the measurement of dielec. consts. of liquids by means of the resonance of 2 high oscillators. Dielec. consts. of Et_2O , CS_2 , CHCl_3 , Me_2CO , EtOH , H_2O are given with an accuracy of approx. $1/1000$ BRIAN MEAD

Breakdown of liquid dielectrics. A. GYEMANT. *Physik. Z.* **26**, 686-7(1925).—G. explains the breakdown of liquid dielectrics on the assumption that the mols. are oriented in rows and that they become capable of exchanging electrons under the influence of a high potential. The presence of "chains" of H_2O mols. would explain the great influence of moisture on the breakdown potential of transformer oils. G. C.

Electric resistance of sodium and potassium in the temperature region of liquid helium. H. R. WOLTJER AND H. KAMERLINGH ONNES. *Proc. Fourth Intern. Congress of Refrigeration* **1**, 183-7a(1924).—Merck and Kahlbaum Na and K tested to temps. down to 1.5°K . showed no supercond. such as had previously been observed for Hg, Pb, Sn, In and Th. A. PAPINEAU-COUTURE

The liquid-helium equipment of the Physikalisch-Technischen Reichsanstalt and some measurements made using liquid helium. W. MEISSNER. *Physik. Z.* **26**, 689-94(1925); cf. *C. A.* **19**, 3178.—M. describes the equipment and detcs. the elec. resistance of Co, Pb, Sn and Au wires from 91.5° to 1.61°K . A correctly aged wire of polycryst. Au has, down to the lowest temp., the same resistance as a monocrystal wire. G. CALINGAERT

Electromotive behavior of aluminium. C. J. DEGRUYTER. *Rec. trav. chim.* **44**, 937-69(1925). (In English).—The passivity of Al is briefly reviewed. A. Smits suggested that the problem of Al could be best attacked with the help of Hg and for that reason this work was undertaken. Fogh (*C. A.* **17**, 3153), Kremann and Müller (*C. A.* **15**, 2771) studied amalgamated Al, while N. R. Dhar (*C. A.* **16**, 1356), Muller and Hölzl (*C. A.* **16**, 3580) and Heyrovsky (*C. A.* **14**, 1773) published papers on the potential of Al in salt solns. The melting diagram of the system Hg-Al was detd. No evidence was obtained for the existence of a compd. between Al and Hg nor for the existence of a transition point. Expts. showed that mixed crystals exist up to about 8% Hg at room temp. The above investigation permitted of deciding upon the E_s diagram for Al-Hg (A. Smits, *Theory of Allotropy*, p. 386). The passivity of Al must be ascribed to the tardiness of the reaction; $\text{Al} \rightarrow \text{Al}''' + 3\text{e}_e$. So far Hg is the best known catalyst for this reaction. It is assumed that $\text{Al}(\text{OH})_3$ is a neg. catalyst

for the internal equil. of metallic Al. Under the conditions used in this work the Al was never covered with an insulating coating of oxide. E. J. WITZEMANN

The physical chemistry of dyes. I. A new method for the determination of the electric charge of dyes in solution. R. FÜRTH. *Kolloid-Z.* 37, 200-4(1925).—An app., designed with the view of avoiding the errors encountered in the detn. of the elec. charge of the particles in colloidal solns. by means of cataphoresis, consists of 2 electrodes, long thin plates made from a clay material which is insol. in the liquids and possesses a white surface so that any coloring of the electrodes can be easily observed. The electrodes are mounted on an insulator support so that the distance between them can be varied. A glass vessel contg. the soln. for measurement rests on a stand and can be raised or lowered to bring the liquid in contact with the electrodes. The d. c. with the necessary high voltage is best obtained by an a. c. transformer in combination with an electrolytic rectifier (Greinacher's). A glowing cathode rectifier was sometimes used. Before an expt. the electrodes were covered with distd. H₂O until all the air was removed and the pores of the stone were completely filled with H₂O. The electrodes were usually 5 cm. apart and stood at a depth of 1 cm. in the soln. About 500 v. was used. For all the aq. or alc. solns. of dyes investigated only a few seconds or min. was required to color one of the electrodes while the other remained uncolored. By a change of polarity in almost every case the color deposited on the one electrode could be removed while the opposite electrode became colored. H. M. McLAUGHLIN

The determination of very small conductivities with the vacuum electrometer. G. HOFFMANN. *Physik. Z.* 26, 913-4(1925). E. J. C.

Magnetostriction in iron crystals. W. L. WEBSTER. *Proc. Roy. Soc. (London)* 109A, 570-84(1925).—Rods about 1.8 cm. long and 1.2 mm. in diam. were cut parallel to the (1, 0, 0), (1, 1, 0) and (1, 1, 1) directions from exceptionally pure crystals of Fe. Simultaneous measurements were taken of the change in length, intensity of magnetization, and strength of magnetic field when these rods were magnetized longitudinally. The (1, 0, 0) axis gave an increase in length and the (1, 1, 1) axis gave a decrease in length for all values of the magnetizing field. For the (1, 1, 0) axis an increase in length was observed for weak fields but an increase was found as satn. was approached. A similar effect was observed for a rod of soft iron and it is suggested that this can be explained by a suitable combination of the effects obtained for the single crystals. The reciprocal relation between magnetostriction and the effect of stress on magnetization was also investigated; the exptl. results agreed satisfactorily with theory (cf. C. A. 19, 1809). W. W. STIFLER

A light filter for polarimetry. N. SCHOORL. *Pharm. Weekblad* 63, 21-3(1925).—The light from an ordinary 50-candle-power filament lamp when filtered through a 2-cm. layer of a soln. contg. 8.8 g. CuSO₄·5H₂O and 9.4 g. K₂Cr₂O₇ in 200 cc. H₂O is monochromatic and has practically the same wave length as the Na spectrum. This filter soln. is recommended in polarimetric detn. of sugars, c. g., glucose in urine and sucrose and lactose in foods, also for the identification of certain optically active oils, e. g., oleum santali. Generalizations of the Rayleigh formula for molecular scattering. J. Q. STEWART. *J. Optical Soc. Am.* **11**, 581-97(1925).—A unified treatment of the Rayleigh, Einstein-Smoluchowski and Cabannes-King formulas is developed from the point of view of classical electrodynamics.

H. R. MOORE

Paramagnetism and the electronic configuration of the atom. L. C. JACKSON. *Nature* **115**, 981(1925).—J. suggests tentatively that the different magnetic states of the ions of iron (Fe^{++}) and cobalt (Co^{++}) may correspond to different internal configurations of the electrons. Thus the ordinary ferrous ion would possess the configuration 2, 8, 14, 0 and the other magnetic state might be produced by the transference of one of the 14 electrons in the incomplete 3rd quantum orbit to the 4th quantum orbit, or by a redistribution of the 3rd quantum orbit electrons among the various levels, 3_1 , 3_2 , and 3_3 , of this orbit. This is analogous to the assumption made by Russell to explain the active and passive states of Fe, Ni and Co. (Cf. *C. A.* **19**, 2773; **20**, 165.)

FLORENCE N. SCHOTT

The metastable $2p_1$ -state of mercury atoms. S. LORIA. *Proc. Nat. Acad. Sci.* **11**, 673-9(1925).—A method is developed, with the aid of the microphotometer, for estimating the duration of metastable $2p_1$ Hg atoms from the intensity increase of the T1 line 5350 Å. U. The value deduced is 5×10^{-12} sec., in fair agreement with Webb's detn (*C. A.* **18**, 3532). It is pointed out that the time of existence in the $2p_1$ state is not const., since it is a function of collisions with other atoms.

H. R. MOORE

Absorption in excited gases. K. W. MEISSNER. *Physik. Z.* **26**, 687-9(1925).—M. det. photometrically the intensity of absorption of the various A lines in the excited gas. All the lines attributed to the $1s_2$ and $1s_3$ states show strong absorption, the $1s_2$ and $1s_4$ little or no absorption, showing that the former have a comparatively much longer life.

EMIL KLARMANN

Structure and size of the non-metallic hydrides. H. G. GRIMM. *Z. Elektrochem.* **31**, 474-80(1925).—If the union between the O ion and the H nucleus were complete, the F ion would result; but since the H nucleus remains at a finite distance from the nucleus of the O ion, there results the OH ion, which is similar to the F ion. Atoms in the periodic system anywhere up to 4 places before an inert gas change their properties by uniting with 1, 2, 3, or 4, H atoms, so that the resulting complexes behave like pseudoatoms, which are similar to elements of the groups standing before them in the periodic table. The energies of dissociation of O_2 and N_2 were calcd. and the results applied in estg. that energy for non-polar mols. The true dimensions of the simpler pseudoatoms were calcd with the use of graphs. By means of these and previous data models of the simpler organic mols. were constructed to show their true relations in size and phys. properties. There are extensive references to the literature of structural chemistry. Discussion follows.

ROSALIE COBB

The continuous spectrum and the γ -ray spectrograph of J. Thibaud. A. PICCARD. *J. phys. radium* **6**, 334(1925).—It is suggested that the continuous background observed in a γ -ray spectrograph by Thibaud (*C. A.* **19**, 2910) may be explained by the absorption of secondary rays in the secondary radiator itself and the possibility of eliminating it by using a sufficiently thin secondary radiator is discussed.

W. F. MEGGERS

The secondary spectra of gamma rays: the origin of the continuous background and the variation of the relative intensity of the lines. JEAN THIBAUD. *J. phys. radium* **6**, 334-6(1925).—The continuous background found on spectrograms of secondary β -rays excited by γ radiation in various elements is not explained by the absorption of the corpuscles in the secondary radiator (cf. preceding abstr.). Expts. on the retardation of β -particles in matter are made by employing high-speed photoelectrons. Their speeds decrease linearly with the thickness of Al traversed. In the spectrograph under discussion all the electrons coming from the lower layers are absorbed and only those form a ray which come from a superficial layer probably less than 0.01 mm. thick for heavy elements. The continuous radiation is, therefore, not an effect of retardation; the origin of this continuous γ -radiation may be nuclear, but it is simpler to admit that it comes from a degradation of the quantum by Compton effect of diffusion in the mass of the radiator. In addn. to a large difference of intensity between the natural and excited spectra, attention is called to the fact that the relative intensities of neighboring β rays are not the same in the 2 spectra.

W. F. MEGGERS

The absorption due to scattering of the canal rays of hydrogen in passing through hydrogen and helium. RICHARD CONRAD. *Z. Physik* **35**, 73-100(1926).—The observed absorption of canal rays of velocities of the order of 2×10^8 cm./sec. in H_2 and He at 0.05 mm. Hg is shown to be due to scattering. A formula for the scattering is worked out especially for the case where the initial beam is conical. In accordance with this formula it is found that the scattering coeff. is proportional to the pressure of the gas and inversely proportional to the fourth power of the velocity of the ray, at least under pressures of 0.02 mm. Hg.

F. R. B.

Atomic number of a radioactive element at the moment of emission of the γ -ray. C. D. ELLIS AND W. A. WOOSTER. *Proc. Cambridge Phil. Soc.* **22**, 844-8(1925).—By measuring the distance between the lines of the corpuscular spectra produced on a photographic plate simultaneously by natural electrons and those excited in Pt, E. and W. show that the emission of γ -ray, which usually accompanies the β -type disintegration actually occurs after the ejection of the electron from the nucleus. The app. used consisted of a thin-walled glass tube 0.4 mm. in external diam. filled with radon and fitted closely into a Pt tube with walls 0.25 mm. thick. Before use this Pt tube was exposed to a source of Ra B and C. The spectra were obtained in the usual way.

E. R. SCHIERZ

The β -type of disintegration. C. D. ELLIS AND W. A. WOOSTER. *Proc. Cambridge Phil. Soc.* **22**, 849-60(1925).—This is a crit. review of work concerning the moment of emission of the γ -ray and the mechanism of emission of these rays and the disintegra-

tion electron, resp. A provisional detailed hypothesis is advanced explaining the mechanism of emission which agrees in general with the conclusions of Meitner except for the moment of emission of the γ -ray. An interesting feature of the hypothesis is that it suggests the existence of a generic connection between the nuclear electronic structure of successive bodies in a family whether the changes be α or β . E. and W. believe that the continuous spectrum of β -rays consists of electrons of disintegration. These electrons are emitted from the nucleus with varying velocities. E. R. S.

A rapid and accurate method of correcting measurements with emanation electroscopes for ordinary changes in temperature and pressure. O. C. LESTER. *J. Optical Soc. Am.* 11, 637-40(1925).—A chart is constructed, by means of which the const. of the electroscopes, corresponding to other readings of temp. and pressure, can be obtained graphically. H. R. MOORE

Extraction and purification of the active deposits of radium of slow rate of evolution. MILLE, IRENE CURIE. *J. chim. phys.* 22, 471-87(1925).—General report upon the recent work of Mme. and Mlle. Curie, with review of methods for detg. the amt. of radiation from active substances. A curie of radioactive substance is defined as the amt. of that substance which emits the same no. of α -rays per sec. as does a g. of Ra. Purification is carried out in carefully cleaned quartz vessels, volatile reagents being used. Gross impurities, as alk. salts and Cu, are removed by pptn. Final purification is effected by electrolysis, by fractional crystn., or by deposition on metals in acid or alk. soln. ROSALIE COBB

Electron paths. A. GÜNTHER-SCHULZE. *Z. Physik* 34, 639-44(1925).—A calcul. on the classical assumptions of the path limits of electrons ejected from a cylindrical filament placed in the center of a plate condenser. The calcul. is applicable to electron tube construction. F. R. B.

Evaporation of electrons. W. SCHOTTKY. *Z. Physik* 34, 645-75(1925).—A discussion of the fundamental of the thermodynamics of thermal emission of electrons, especially in connection with the work of Raschevsky (*C. A.* 19, 3062) leads to the conclusion that the important factor is not the heat capacity of the electrons but the variation in the sp. heat of the metal due to the electrons. This quantity which is Lewis and Randall's partial molal heat capacity is not directly measurable but is connected with the Thomson heat and with the temp. coeff. of thermoelec. force. S.'s equation does not allow of immediate calcul. but is of theoretical interest. F. R. B.

The flashing of certain types of argon-nitrogen discharge tubes. WM. CLARKSON. *Proc. Phys. Soc. London* 38, 10-5(1925).—An account of investigations on the flashing of discharge tubes which had various types of electrodes, and in which the filling gas, a mixt. of A and N, had a wide pressure range. At higher pressures the discharge was no longer of the "glow" type, but took place between definite points on the electrodes. MARIE FARNSWORTH

The influence of temperature on the photoelectric effect of the alkali metals. H. E. IVES AND A. L. JOHNSRUD. *J. Optical Soc. Am.* 11, 565-79(1925); cf. *C. A.* 19, 603.—A new technic is developed for investigating the variation of photoelec. current with temp. for Na, K, Rb and Cs point by point within the temp. interval -180° to $+20^{\circ}$. The temp. was maintained uniformly over all parts of the illuminated electrode and the deleterious effects of occluded gases avoided by condensation on the outer alkali-coated walls. The decrease of photoelec. current with temp. was continuous for all metals, and was greater for yellow than either blue or white light. A special study of annealed and roughened K surfaces has disclosed the importance of this factor. It is concluded that variations in photoelec. effect are intimately connected with strains produced in the surface by expansion and contraction with temp. H. R. MOORE

Some experiments on collisions of the second kind. H. D. SMYTH. *Proc. Nat. Acad. Sci.* 11, 679-82(1925).—When free electrons come within the fields of force of excited atoms about to revert to the normal state, they rebound with kinetic energies equiv. to the activation energy of the atoms concerned. This effect is demonstrated with monat. I, which possesses an electron affinity of 3.5 v. When the current flowing in a 3-electrode tube is plotted as a function of the retarding field between the grid and anode, a stream of electrons is detected with velocities 3.0-5.0 v. greater than the main group. A similar effect is found for the decompn. of O_2 at 300° . With more refined methods it may be possible to demonstrate the existence of 3 beams of electrons, produced by collisions of the second kind, of velocities 0.52, 1.73 and 4.3 v. The corresponding crit. increments of activation of the O_2 mol. are 12,000, 40,000 and 110,000 cal., resp. H. R. MOORE

The generally accepted explanation of the Zeeman triplet on a quantum basis.

W. M. HICKS. *Nature* 115, 978(1925).—In applying Larmor's theorem to the explanation of the simple Zeeman triplet on the basis of the quantum theory the assumption is made that after the imposition of the magnetic field the rotating system is the same as before with simply the rotation superposed. This assumption is incorrect and leads to two further objections that (1) the new orbit ceases to be quantized and (2) the total energy is supposed to be altered by the action of a magnetic field on a moving electron.

FLORENCE N. SCHOTT

New determinations in the electric field. W. STEUBING. *Physik. Z.* 26, 915-9 (1925).—A field of 57 kv./cm. failed to produce any effect on the negative CO bands, 97 kv./cm. failed to alter the moisture bands in the ultra-violet. S. concludes in general that a Stark effect cannot exist for band spectra to an extent detectable by our present methods.

F. O. A.

Heating effect of the anode in a glow discharge. II. F. M. PENNING. *Physica* 5, 217-33(1925).—The app. with the double calorimetric anode, as described in a previous article (*C. A.* 19, 1372) was improved. Two anode blocks constructed of Cu, contg. heating element, thermocouple, etc., were suspended from 3 thin iron wires, inside the vacuum tube. The cathode consisted of a circular plate surrounded by a flat ring; the measuring method was the same. The results are given in v - p and v - i_a curves (v is heat effect expressed in v. for const. i_a ; p is pressure of Ne, i_a is current density). At pressures of 10 to 20 mm. 2 forms of anodic light are possible, depending on p and i_a , the usual thin yellow layer and a red hemisphere; either one is stable, red between 2 and 10 mm. Oscillations are excluded on account of the low current values: 2 or 5 ma. The v values for red light are lower than those for yellow light. As the pressure is diminished the red ball gradually changes its shape and color, giving the yellow layer again. Simultaneously the v - p curve for red goes through a min. (4.5 mm., 22 v.) and rises up to 29 v., this being the value for yellow light. Below 2 mm. v drops suddenly to 5 v. with disappearance of all anodic light. These results are in agreement with conclusions of Günther-Schulze (*C. A.* 19, 1091), the anodic glow being due to a negative space charge, lack of sufficient positive ions. Potential for the dark discharge is only 1 v. more than ϕ for copper (4.0 v.). The increase in v accompanying the anode glow is of the order of $\phi + v_i = 25.5$ v. In the red discharge the anode fall is extended over a larger distance, more chances for the electrons to collide and ionize, consequently smaller potential drop. Another explanation of the red ball on the basis of stepwise ionization seems less plausible. The author, contrary to G.-S., ascribes the lack of positive ions near the anode to excessive diffusion; a slightly negative potential of the auxiliary anode or even of the glass walls, caused an anodic potential drop to appear by capturing the ions. Variation of the electrode distance (d) gave results similar to those of G.-S.; for const. i_a and p , increasing d , v rises rather suddenly over 20 v., yellow glow appears ($i_a = 0.6$ ma., $d = 15$ mm.); d still larger (31 mm.) gives the red ball with a 3 v. potential drop. More evidence for an anode fall of about 20 v. was obtained in a different type of tube with two circular electrodes and a small "test" electrode (S) near the anode in the sidewall (method of Langmuir, *C. A.* 19, 1531). This method is, however, less reliable, the dimension of the space charge before the collector may not be small with regard to the electron free path. Curves of $\log i_s = f(v_s)$ for $i_a = 20$ ma. (yellow glow) and for $i_a = 5$ ma. (dark anode) show that a difference of about 19 v. in v_s is necessary to bring about the same collector current i_s . The potential of the anode relative to the surrounding space has increased with this amt.

B. J. C. VAN DER HOEVEN

Photoelectric conductivity at low temperatures. B. GUDDEN AND R. POHL. *Z. Physik* 34, 248-54(1925).—The photoelec. cond. of NaCl crystals which have been colored by exposure to X-rays is measured over the range 20-80° Abs. At the lower temps. the max. cond. is shifted to the shorter wave lengths; at zero Abs. the max. is approx. at 380 m μ . A possible connection of this value with the ionization potential of metal Na is pointed out.

F. R. B.

Proof of the selective photo effect. B. GUDDEN AND R. POHL. *Z. Physik* 34, 245-8(1925).—A coating of Na or K deposited on an insulator such as quartz and NaCl when illuminated by ultra-violet and violet light loses electrons which under high elec. fields pass through the insulator producing a photoelec. change in resistance. This phenomenon is presumably connected with the photosensitivity of NaCl crystals that have previously been colored by exposure to X-rays.

F. R. B.

The reported $K\alpha$ line in the X-ray spectra of molybdenum and palladium. S. K. ALLISON. *Nature* 115, 978-9(1925).—No evidence for the β_1 line reported by Leide (cf. *C. A.* 19, 1987) was found. A discontinuity in the general radiation always appeared due to the absorption by the target of its own radiation. The effect produced by this

absorption might be mistaken for a faint line on the short wave-length side of the γ -line.

Spectroscopic evidence of J-transformation of X-rays. MANNE SIEGBAHN. *Nature* 116, 11(1925).—Khaustgir and Watson (cf. *C. A.* 20, 146) plotted the wave lengths of the X-ray line *K* against the at. no. of the elements nos. 48–60 and noted irregularities at $n = 52$ and 56, which they ascribed to the J transformation of X-rays. They refer to the work of Siegbahn for these data. S. disclaims some values given. Recent work done by S. and Leide (cf. *C. A.* 14, 689) gives values for wave lengths which when plotted against the at. no. show no trace of discontinuities as described by Khaustgir and Watson. W. W. NIPPER *Ibid* 12(1925).—N. points out that the values used by Khaustgir and Watson (*C. A.* 20, 146) were obtained in 1915 by Malmer (See "Atomic Structures," Sommerfeld, p. 153). When values of λ according to Siegbahn's latest work ("Spektroskopie der Roentgenstrahlen," 1924, p. 101–2) are plotted against the at. no. the curve obtained is smooth and no discontinuities are obtained. There is, therefore, no spectroscopic evidence of the so-called J-transformation of X-rays. S. R. KHAUSTGIR AND W. H. WATSON. *Ibid* 47(1925).—Controversial and explanatory.

FLORENCE N. SCHOTT

The spectra of ionized lithium. Y. SUGIURA. *J. phys. radium* 6, 323–33(1925).—The spark spectrum of Li has been obtained from a discharge tube provided with a perforated cathode, the inner walls of which are covered with LiCl. The discharge is produced by an induction coil with 50,000 to 80,000 v., the circuit contg. also a condenser in parallel and an external spark gap in series. The same arrangement permitted observations of the Stark effect on certain Li-arc lines and produced 55 lines of the first and second spark spectra of Cl. The wave lengths of about 40 spark lines of Li are measured between 2607 and 5485 Å. Most of these lines are classified in series analogous to those of He and the quantum defects corresponding to each series term are compared in the 2 spectra. The values of the terms are calc., that of the term $1s$ is found to be 546,703 cm^{-1} which corresponds to a second ionization potential of 67.5 v. The crit. potentials deduced from the spectroscopic measurements are in agreement with the potentials observed by Mohler and with the theoretical values calc. from the at. models of Bohr and Kramers.

W. F. MEGGERS

The absorption spectra of various aldehydes and ketones and some of their derived compounds. J. E. PURVIS. *J. Chem. Soc.* 127, 9–14(1925).—Spectral absorption measurements of various org. compds. with a Cd spark as source have lead to the following conclusions: (1) all aldehydes and ketones exhibit selective absorption in the ultra-violet which disappears when the CHO or C=O groups are neutralized or eliminated; (2) substances with unsatd. centers such as C=C or C \equiv C bonds in straight chain and aromatic compds. give sp. absorption; (3) with progressive elimination of the oscillatory centers the absorption is shifted to the more refrangible regions. A special study of CH₂O and its polymers (cf. P. and McClelland, *C. A.* 7, 564–5) in various solvents, has enabled P. to demonstrate interaction with the solvents by shifts in the absorption bands.

H. R. MOORE

Band spectra of lead isotopes. E. S. BIELER. *Nature* 115, 980(1925).—It has been shown (cf. *C. A.* 16, 679) that in the case of U Pb, the lines of the band at 4270 showed an av. shift to the violet of 0.055 Å.U., as compared with those of ordinary Pb and that the lines were much sharper in the former case than in the latter. A satisfactory explanation is obtained by assuming that the lighter PbH mol. is the carrier of the band rather than the heavier Pb₂ mol. (Cf. *C. A.* 17, 3135; 19, 1223, 1985)

FLORENCE N. SCHOTT

Photochemical reaction between bromine and tartaric acid in aqueous solution. I. JNANENDRA CHANDRA GHOSH AND JADULAL MUKHERJEE. *Quart. J. Indian Chem. Soc.* 2, 165–78(1925).—The dark reaction between C₄H₆O₆ and Br₂ manifests an induction period of 2 days or more; in intense light no induction period is observed. In blue light (wave length 450–90 μ) of intensity 5400 ergs/sq. cm./sec. an induction period of 120–50 min. was observed at 34.3°, after which the disappearance of Br₂ followed a monomol. equation. The reaction velocity was found to be independent of the state of polarization of the incident light; unlike most photochem. reactions, a temp. coeff. (for 10°) of as much as 1.7–2.0 was found. Five min. initial exposure to bright sunlight caused a reaction which was initially very rapid, but which had almost ceased at the end of 1 hr.; this was explained by postulating the formation of a compd. of C₄H₆O₆ and Br₂ which decompd. with a reaction velocity relatively much greater than that of the reaction between C₄H₆O₆ and Br₂ in the dark.

E. H.

The photochemical oxidation of leuco-bases. B. H. CARROLL. *J. Phys. Chem.* 30, 130-3(1926).—The leuco-bases of triphenylmethane dyes were incorporated in collodion films; the oxidation is accelerated by N bases. Sensitivity is low, but there is no evidence of induction; reaction is proportional to intensity. B. H. CARROLL.

The mechanism of photochemical reactions. MAX BODENSTEIN. *Trans. Faraday Soc.* 1925 (advance proof).—The quantity of light absorbed is the principal factor in controlling the velocity of photochem. reactions. Conc'n. is an important factor, however, since the simple law $dx/dt = nI_{\text{abs.}}$ connecting energy with mass is applicable only when the process of energy transference to other mols. is negligible. The researches of Cario and Franck and of Wood on the extinction of fluorescence by foreign gases show that the ordinary laws of kinetics must be modified for chem. reactions at low pressures; that is, when the period between collisions is greater than the av. duration of excitation (10^{-8} sec.). Chain reactions are possible when the const. n in the above expression assumes values higher than 1 and Einstein's law is invalidated. Studies of the influence of foreign gases on the decompn. of HI (Warburg, *C. A.* 12, 2490) and of O_3 by Cl_2' (where Cl_2' denotes an activated mol.) are deemed pertinent in this connection. The recent expts. of Kistiakowski (*C. A.* 20, 711) have shown that He and other indifferent gases inhibit the decompn. of O_3 . In all probability the excitation energy of the O_3 is retained as surplus "flight energy" by the colliding He mols. A knowledge of secondary photochem. processes is contingent on the exact definition of unstable intermediate products and a means of estg. their velocity of conversion. H. R. M.

Chemical changes produced by light energy. G. W. PUCHER. *Buffalo General Hospital Bull.* 3, 76-82(1925).—A review with bibliography of 65 references.

NATHAN VAN PATTEN

Photosensitization by optically excited mercury atoms; the hydrogen oxygen reaction. A. L. MARSHALL. *J. Phys. Chem.* 30, 34-46(1926).—The reaction between H_2 and O_2 was sensitized to ultra-violet light of wave lengths shorter than 2900 Å. U. by using the method of Taylor and Marshall (cf. *C. A.* 19, 3418). A light filter which absorbs all radiation between 2900 and 5000 Å. U. was used (Cl_2 at 2 atm. + Br_2 at 60 mm.). When the amt. of H_2 exceeds that necessary for complete combination with the O_2 present, the reaction rate (pressure decrease at 50° is 24.7 mm./min.) is independent of total pressure down to a partial pressure of H_2 and O_2 of a few mm. When O_2 is in excess, HgO is formed from the Hg present and this results in variable light absorption and consequently variable combination velocities. The kinetic equation favored is: $d[H_2O]/dt = K[H_2]/([H_2] + [O_2])$. To account for the reaction rates observed, a chain mechanism is postulated. D. S. VILLARS

Dissociation and fluorescence of iodine vapor. E. G. DYMOND. *Z. Physik* 34, 553-61(1925).—I vapor may be made to fluoresce by light of wave lengths greater than 4995 Å. U. For wave lengths shorter than this, e. g., in the region of the continuous absorption band of I, no fluorescence takes place. This D. interprets as due to the fact that in this region the energy absorbed (2.5 v.) is great enough to dissociate the atom (1.4 v.) and to excite one of the atoms to the $2p_2 - 2p_1$ state. He was not able to prove this assumed dissociation by measuring the density of resonated I vapor but he believes this is due to the fact that the activated atom is adsorbed by the walls. A new group of fluorescent lines was discovered by exciting the vapor with Cd, $\lambda = 5086$, Cu, $\lambda = 5218$ and Na, $\lambda = 5893$. F. R. B.

Polarized fluorescent light in dye solutions. S. I. VAVILOV. *Z. Physik* 32, 721-9(1925); cf. *C. A.* 19, 1663.—The measurements of polarized fluorescence are made with a König-Martens spectral photometer, adapted for use as a spectro-polarimeter. Data procured on the degree of polarization in glycerol solns. of fluorescein and rhodamine B show conclusively that polarization is independent of wave length throughout the fluorescent band. Solns. of fluorescein in H_2O and MeOH show no measurable polarization at high concns. Further fluorescent depolarization is examd. for increasing concns. of fluorescein in glycerol and erythrosin in H_2O . In the former case, the degree of polarization is diminished from 38.5 to 0.2% and the diminution of polarization begins prior to the extinction. V. concludes that not every collision between dyestuff mols. which produces depolarization, produces extinction at the same time. H. R. MOORE

Studies in luminescence. DOROTHY G. ENGLE AND B. S. HOPKINS. *J. Optical Soc. Am.* 11, 599-615(1925).—An app. is described for measuring directly the intensity of luminescence with a Cs photoelec. cell. Cathode rays are used for excitation. The color of fluorescence is influenced by the following factors: (1) nature of the sensitizing agent, (2) amt. of sensitizer, (3) temp. of fusion, (4) time of fusion, (5) nature of exciting

agency, (6) at. wt. of base used. The substances ZnS , $\text{Ca}(\text{PO}_3)_2$, ZnSiO_3 are studied in detail. H. R. MOORE

Radium emanation. V. F. HESS and E. D. LEMAN. U. S. 1,570,834, Jan. 26. A portion of the gases is removed from Ra emanation, the partially purified emanation is passed to a tube contg. an absorbent to obtain the emanation in a state of substantial purity and the portion of the tube contg. the absorbent is sealed off, so that the remaining portion of the tube contains only substantially pure emanation.

4—ELECTROCHEMISTRY

COLIN G. FINK

Some applications of electric heat in chemical industries. R. M. KEENEY. *Chem. Met. Eng.* 32, 922-5(1925); cf. C. A. 20, 338, 339.—The last instalment of a series dealing with important applications of industrial heating. It covers the *baking industry*, the *manuf. of chemicals and driving paper*. Indications are that the industrial heating load will soon exceed that of the elec. furnace in the U. S. The *glass industry* offers a promising field for investigation for the use of elec. heat. W. H. BOYNTON

Electrical application in the steel industry during the year 1925. J. D. WRIGHT. *Blast Furnace & Steel Plant* 14, 89-91(1926). E. H.

Electric furnace progress in 1925. FRANK HODSON. *Blast Furnace & Steel Plant* 14, 66-71, 108(1926).—Metallurgical applications of the elec. furnace are reviewed. E. H.

Laboratory electric furnaces. ANON. *Elec. World* 87, 179(1926).—Small elec. furnaces have been designed for special lab. heats, ranging in capacity from 500 lbs. (22.7 kg.) down to a ladle or crucible type furnace of 50 lbs. (2.27 kg.). In most of the furnaces the superstructure and roof refractories are so designed that the furnace can be operated on direct or indirect arc circuits. Micrometer cranks are used in hand adjustment of electrodes, while for automatic control winch motors are employed. W. H. BOYNTON

Graphite-tube vacuum electric furnace. ANON. *Engineering* 121, 42-3(1926).—See Partington and Anfilogoff (C. A. 20, 551). A. D. S.

Producing clear fused quartz electrothermally. E. R. BERRY. *Chem. Met. Eng.* 32, 915-6(1925).—B. reviews the discoveries which led up to the production of clear fused quartz. B.'s method consists in fusion of SiO_2 crystals *in vacuo*, permitting most of the bubbles to escape, followed by fusion in N at high pressures to diminish the vol. of the remaining bubbles. Expts. are described comparing glass and quartz thermometers, in which the glass thermometer shows an error of 1.5° on being brought back to 0° after being heated to 510° , while the quartz thermometer reads correctly. A gallium-in-quartz thermometer is described (Boyer, C. A. 20, 538). Held at 1000° for 24 hr. it was not injured, and it appears to bridge the gap between 500° and 1000° satisfactorily. It is not advisable to hold quartz above 1000° for any considerable period. A process of drawing sheet quartz directly from the elec. furnace has been perfected. H. S.

The electrolytic production of heavy metals from fused salts. I. The production of iron. F. SAUERWALD AND G. NEUENDORFF. *Z. Elektrochem.* 31, 643-6(1925).—In the production of Fe, carefully purified oxide, contg. 25.1% FeO and 74.6% Fe_2O_3 , is used as well as ordinary oxide contg. 44.7% Fe^{++} and 23.8% Fe^{+++} . A mixt. of 75% of the first with SiO_2 (98.2%) m. 1220° and is a clear liquid at 1260° . By using the purified oxide, with a current of 25-50 amp., 39.8 g. of Fe are obtained in 30 min., the

cell being kept at a temp. of 1300°. In another cell the anode was C and the cathode Fe, spaced 7 cm. apart; with the purified Fe oxide, 10–13 v., 400–800 amp. being used, 258 g. of Fe were sepd. in 3 hr., the temp. being kept at such a point that the Fe separates in the solid state. By repeating this expt. at a cell temp. of 1700°, 109 g. of liquid Fe are deposited in 2 hrs. at 400–700 amp., 20–50 v. Microscopic examn. showed the Fe to be quite pure with only traces of Si. Photomicrographs are shown. The ordinary type of oxide was treated in this cell at 200–400 amp., 30–40 v., electrode spacing 6 cm. The temp. could not be raised above 1500°, without injury to the lining of the cell. H. STOERTZ

The formation of alkali amalgam by alternating current electrolysis. SVEN BODFORSS. *Z. Elektrochem.* 31, 646–9(1925).—When caustic alkali soln. with Hg electrodes is electrolyzed with a. c., although the av. potential of the electrodes is below that at which alkali amalgams are formed, the potential rises above that momentarily and a small quantity of the amalgam is formed. This diffuses into the Hg and is somewhat protected against oxidation when the current is reversed. The presence of *hydrazine* gives further protection against oxidation during the anodic pulsation. B. avails himself of this fact to prep. *K-amalgam*, using for electrolyte 1 N KOH with varying quantities of hydrazine hydrate or sulfate, 48 cycles a. c., and 0.2 to 0.4 amp. The presence of K in the Hg is demonstrated by measuring its potential against Zn. The potential fall of K-amalgam is plotted with varying amts. of hydrazine, the curves indicating the formation of an intermediate product of K and hydrazine. H. STOERTZ

Refrigeration in the electrolysis of liquor (salt solutions). J. & E. HALL, LTD. *Proc. Fourth Intern. Congress of Refrigeration* 1, 912–7(1924).—Discussion of the advantages of refrigeration in electrolysis of solns., more particularly in the production of electrolytic NaOCl in hot climates, with a description of refrigerated electrolyzers. A. PAPINEAU-COUTURE

Simple method for the preparation of fluorine. P. LEBEAU AND A. DAMIENS. *Compt. rend.* 181, 917–9(1925).—In the method of Argo, *et al.* (*C. A.* 13, 1188) there is considerable loss of HF from the molten bath, resulting in a rise in temp. of the bath and greater danger of attack of the graphite anode and Cu container and of contamination of the F with CF₄. These drawbacks are overcome by using a bath of KF·3HF (instead of KF·HF), m. 56°, and electrolyzing at not over 150°. The anode may be of Fe, or preferably Ni (because of its greater purity, especially as regards C content). The KF·3HF, prepd. by adding the theoretical amt. of HF to KF·HF, is placed in a Cu or Ni container which acts as cathode. The anode is an 8-mm. Ni rod placed vertically through the neck of a bottle-shaped Cu jacket, over which is the F outlet tube, and the bottom and sides of which are perforated to allow circulation of the electrolyte. The F partly adheres to the Cu bottle, forming a film which insulates it from the circuit. Higher yields are obtained than heretofore. A. PAPINEAU-COUTURE

The electrodeposition of metals. I. Theory of the mechanism. PER K. FRÖLICH AND G. L. CLARK. *Z. Elektrochem.* 31, 649–55(1925).—In the first type of polarization phenomena, as with Hg and Cu in simple salt soln., the c.d.-cathode potential curves are smooth, bending slightly, and show only concn. polarization. With the second type, when complex salts are used, the c.d.-potential curves show an increase in the cathode potential in addn. to that due to concn. polarization because of chem. polarization. Previous authors postulate an intermediate colloidal or hydrated phase, particularly in the third case of deposition in the presence of a colloid. The present authors found that concn. polarization simply increased, since convection, diffusion and migration decrease. The Fe group metals are considered. No proof was found for the existence of an intermediate state in electrodeposition and the formation of the deposit is not an independent crystn. process. After giving up its charge, the metal ion immediately takes its place in the space lattice of the crystals already upon the cathode. (With the exception of the case where the metal ion set free serves as the nucleus for a new crystal.) The discharge of ions and the crystn. of the discharged ions are so closely interwoven that they must be considered as 1 process. Considerable evidence is adduced in support of the hydride theory of H overvoltage. The series: Pd, Pt, Ta, Ni, Co, Fe, Zn, Cu, Au, Hg is given in the order of increasing H overvoltage and of decreasing metal overvoltage. Metal overvoltage is the greatest with the metals at which the H overvoltage is the least and vice versa. The greater the tendency of the metal to form hydride, the greater is the resistance which is opposed to its deposition. Alloying metals seems to exert an influence similar to H in resisting the formation of the normal space lattice of a metal. True metal overvoltage is caused by the action of H during the building up of the normal space lattice of a metal, while the discharge process itself is reversible for all metals. II. X-ray investigation of electrolytic

nickel. G. L. CLARK AND PER K. FRÖLICH. *Ibid* 655-8.—Previous work is reviewed. The authors give their findings in the X-ray examn., by 3 methods, of Ni deposited on Pt, Ni and Al from 8 different baths at various c. ds and temps. The av. thickness of Ni deposited was 0.006 in. (0.15 mm.) thick. Ni deposited upon Ni and Pt showed the structure of the base metal plainly. Low c. d. is favorable to the formation of the fibrous structure. Higher temp. is less favorable for the orientation than low and produces larger grains. The p_H of the soln. and the electrode potential have a certain influence which could not be ascertained from the X-ray diagrams. H evolution hindered the uniform arrangement of the grains. The influence of C in the deposit is not clear; although gelatin disturbs deposition it still assists the uniform arrangement of the Ni crystals. In several cases another orientation normal to the rolled surface of the electrode was observed. Under certain conditions the deposit has the tendency to reproduce the underlying structure. Greasing the electrode, cleansing and preliminary prepn., whether the base metal is cold rolled or cast, influence the structure of the deposit. Ni is deposited in completely unoriented arrangement upon Al because of the oxide layer. The nature of the deposit is detd. by the base metal as well as by the conditions of electrolysis. The X-ray results indicate that the discharge of Ni ions and the deposition of metal are simultaneous processes and that there is no intermediate state of a colloidal nature. A proof of hydride formation for the purpose of explaining overvoltage could not be obtained because of the instability of the solid soln. of hydride in metal after removing the electrode from the bath. G. DURPERNELL

The electrolytic deposition of nickel. R. SAXON. *Chem. News* 132, 4(1926).—Electrolyzing a soln. contg. NiSO_4 400 parts/l., K_2SO_4 100 parts/l. for 5 hrs with the "lighting" current through 3 lamps for resistance gives 21% H_2SO_4 , and an abundant deposit of Ni hydrate followed by a deposit of the metal G. DURPERNELL

Standard electrical cells. MARION EPPLEY. *J. Franklin Inst.* 201, 17-46(1926).—The principle cells used as practical standards for comparison of e. m. f. are discussed, as also the conditions which various investigators believe should be fulfilled by a satisfactory standard. A. D. S.

The seat of the electromotive force in the galvanic cell. J. A. V. BUTLER. *Chemistry & Industry* 45, 3-5(1926); cf. *C. A.* 19, 611.—The relation of galvanic action to the *Pellier effect* is indicated and the relation to the existence of large metal contact p. ds. is discussed. Metal contact p. d. is of the same order of magnitude as the e. m. f. of the cell. The metal junction contributes largely to the e. m. f. Energy changes at the metal electrodes are considerably less in magnitude than at the metal junctions. Metal ions in a cryst. lattice are vibrating about their equil. positions in accordance with their thermal energy. A means of calcg. the no. of ions in the metal surface which will acquire sufficient energy in their thermal agitation in a given time to overcome the attractive force of lattice and escape into the soln. is pointed out. In this discussion free metals, ions and electrons are regarded as normal constituents of a metal. The Nernst theory is shown to give a satisfactory representation of the process at the metal electrodes. Unsolved problems of the galvanic cell concern chiefly the relation between free energy and total energy. W. H. BOYNTON

Electrolytic condenser. A. SOULIER. *Bull. soc. franc. electriciens* No. 46(1925); *Elec. World* 86, 1166.—An arrangement consisting of certain metals used as electrodes in an electrolyte and below a voltage which is sufficient to cause electrolytic action exhibits the characteristics of a condenser. This peculiarity is ascribed to a film of oxide or gas which forms on the electrodes and has a life of about 1 day. Accordingly the condenser has to be charged daily. It is applicable to power factor correction, motor starting, etc. Al electrodes were used in making a com. electrolytic condenser with a crit. potential of 350 v. per cell. A. D. SPILLMAN

Electrical breakdown of air. F. FERNIE. *Electrician* 96, 59-65(1926).—A theory is discussed of energy distance from 2 points of view. "Energy distance" as applied to breakdown of a gas seems to mean the distance which an ion, in an elec. field, requires to accelerate sufficiently to acquire a velocity which will enable it to create new ions by collision with gas mols. The ionic theory is shown to be unsatisfactory and an alternative theory derived which is based on the assumption that ions in the elec. field are negative, i. e. electrons. Exptl. results on needles and spheres are shown. The d. of electrons depends on the voltage gradient at the surface of the electrode. The flux of electrons will vary as the potential gradient at the surfaces of the spheres, and as the surface areas of the spheres. As the radius of the sphere increases the flux d. (gradient) necessary to produce the breakdown decreases. One objection to the energy distance theory is that it fails to connect the tube theory with the open tube theory.

The theory developed is for high elec. pressure and atm. air pressure. Application is shown to concentric electrodes. The breakdown between concentric electrodes with solid insulation depends on the gradient at the cylinder surface. The theory explains how the crit. gradient may be at the surface of the cylinder and yet the actual breakdown begin at the surface of the inner electrode. The theory has crudities but may serve to suggest further exptl. work.

W. H. BOYNTON

Conductivity tests of wires and cables. H. M. FRIEND. *Elec. World* 87, 151-2 (1926).—By measuring the resistance and the temp. of the cable, and by reference to tables showing the resistance in ohms of pure Cu, for solid conductor, or for soft annealed Cu of 1 circular mil cross-section, if stranded, a value is secured which is sufficiently accurate for com. tests. By this means the theoretical value for pure Cu is obtained. By dividing this value by that secured by the bridge on the cable being tested, the % cond. is obtained. The derivation of the tables for solid and for stranded conductors is shown. A slight inaccuracy enters, because of the fact that the temp. coeff. of Cu varies with the cond., results being higher at temps. above 20° and lower at lower temps.

W. H. BOYNTON

Hydrogen for hydrogenation of oils (KNOWLES) 18. Cleaning steel sheets (Brit. pat. 236,241) 9.

Incandescent lamps. A. DE GRAAFF and D. LELY, JR. U. S. 1,560,981, Nov. 10 P₄O, BaN₂ or a similar non-hygroscopic substance, adapted when heated to a certain temp. to be decomposed with consequent formation of a hygroscopic substance, is placed in a lamp enclosure which is then exhausted and sealed at a temp. below that at which the added substance decomposes. The substance is then subjected to a decomposing temp. to form a compd. within the lamp which serves to eliminate traces of H₂O vapor.

Electric battery of the Leclanché type. B. NEWTH and O. NEWTH Brit. 236,531, July 7, 1924.

Dry batteries. G. B. ELLIS. Brit. 235,302, March 11, 1924. Zn battery cups are made by extrusion at a temp. of 150°, with soft blanks (preferably under 23 scleroscopic hardness) contg. less than 0.6% Pb and 0.5% Cd, formed free from grain, as produced by pack rolling or by transverse rolling of a 1 in. ingot down to 0.15 in.

Gas vents for electric batteries. THREE STAR ACCUMULATORS, LTD. and C. KENDALL. Brit. 236,398, Aug. 1, 1924. Structural features.

Storage batteries. W. B. STONE. Brit. 234,954, April 14, 1924. Structural features.

Storage batteries. F. J. BROWN. Brit. 234,921, March 12, 1924. Separators for storage batteries comprise woven wood strips and a porous diaphragm of wood, perforated ebonite, celluloid or the like.

Storage battery. W. H. SIMMS. Brit. 236,316, April 17, 1924. Structural features

Storage battery. R. A. HOFFMAN. U. S. 1,571,333, Feb. 2.

Storage battery. J. C. BALDWIN. U. S. 1,570,722, Jan. 26. Structural features.

Storage battery. SOC. ANON. LE CARBONE. Brit. 235,530, June 14, 1924. An active material for Pb batteries comprises a mixt. of 60% of powd. Pb or oxide of Pb and a porous conductor in small grains (e. g., charcoal of different finenesses mixed together) which has a large gas-absorbing capacity. The active material may be impregnated with 10-15% Bé. H₂SO₄. Various structural features also are specified.

Composition of lead and mercury. A. MILLER. U. S. 1,570,763, Jan. 26. A compn. adapted for making storage battery plates comprises Pb 90 and Hg 10%.

Electric resistance furnace. L. SATCHWELL. Brit. 235,921, Oct. 21, 1924.

Electric resistance muffle furnace. L. W. WILD, E. P. BARFIELD and J. D. COLEMAN. Brit. 235,993, April 24, 1924.

Electric resistance furnace for annealing. AKT.-GES. BROWN, ROVERI, ET CIE. Brit. 235,490, Aug. 13, 1924.

Electrolytic cell for deposition of metals such as iron, nickel and cobalt. T. W. S. HUTCHINS. Brit. 235,123 and 235,272, March 4, 1924. Special app. is described adapted for use in the process of Brit. 197,066 (C. A. 17, 3646).

Selenium cells. R. HART. Brit. 236,266, March 31, 1924. Details are given of sublimation of Se for deposition on a grid in cryst. form and prep. cells for photoelec. use.

Auxiliary cadmium electrode, etc., for testing secondary batteries. A. W. RAYWORTH. Brit. 236,284, April 3, 1924.

Furnace electrodes. INTERNATIONAL GENERAL ELECTRIC CO., INC. Brit. 235,596, June 14, 1924. Sectional electrodes are formed with a C core and a shrunk-on metal tube over the core. For a steel furnace, an Fe tube 4-10 mm. thick is shrunk on a C core 250 mm. in diam.

Electrodes for electric furnaces. NORSKE AKTIESELSKAP FOR ELEKTROKEMISK INDUSTRI NORSK INDUSTRI-HYPOTEKBANK. Brit. 235,894, Jan. 17, 1924. Structural features of electrodes, which, if used for Al manuf., may have a mantle and ribs of Al.

Electrodeposition of cadmium and nickel. UDYLITE PROCESS CO. Brit. 235,159, June 5, 1924. See U. S. 1,537,047 (C. A. 19, 1824).

Tungsten. NAAMLooZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 236,152, June 27, 1924. W powder is deposited by electrolysis of tungstates, e. g., Li tungstate or a eutectic mixt. of Li and K tungstates m. 500° or a mixt. of Na and K tungstates m. 650°. An excess of WO_3 may cause the pptn. of "W bronzes" and to prevent this alkali peroxides or other alkali oxides or hydroxides may be added. A SiO_2 crucible and W electrodes may be used for the electrolysis. The temp. should be above 900°. Brit. 236,153 specifies electroplating with W, similarly.

Apparatus for electric precipitation of suspended particles from gases. SIEMENS-SCHUCKERTWERKE GES. Brit. 235,582, June 12, 1924. Pptn. electrodes are formed of asbestos slate, asbestos cement, magnesia, $MgCl_2$, asbestos mixt. or of a semi-cond. binder such as cement or gypsum and a fibrous material such as asbestos, slag wool, hairs or wood fibers. Graphite, C powder, metal powders or metal oxides may be added to increase the cond.

Electroplating. B. BART. U. S. 1,570,819, Jan. 25. A series of anodes is used and the article plated is moved through the bath so as to expose it repeatedly to elec action of various intensities from the different anodes.

Electrolytic rectifier. FANSTEEL PRODUCTS CO., INC. Brit. 235,658, March 22, 1924. A Ta electrode and an electrolyte of 1.2 sp. gr. H_2SO_4 are used, the other electrode being Pb or C. The temp. of the cell is kept low.

5--PHOTOGRAPHY

C. E. K. MEES

Fading of the latent image. P. STRAUSS. *Das Atelier* 32, 76-7(1925); cf. C. A. 19, 445.—The latent image of an exposed film is very stable if the film is stored in a dry state and kept dry throughout the period of storage. It is reduced if the film is moist or is allowed to take up moisture during packing. The latent image is often entirely destroyed by vapors of various acids, such as hydrochloric, sulfurous and carbonic. Reduction of the latent image proceeds in a manner similar to persulfate reduction. The rate of fading is greatest in areas which received the most exposure. J. F. R.

Toning sulfided silver prints with silver. A. STEIGMANN. *Das Atelier* 32, 72-3 (1925).—Some of the Ag_2S in a sulfide-toned print is very finely divided. The particles can act as nuclei for the pptn. of Ag from Lumière's Ag intensifier. In practice a sulfided print is treated with the intensifier until the tone changes from brown to chocolate brown and then is washed and dried. The image contains finely divided Ag which can be bleached and toned with Au or Se. The process can be modified by the use of a mixt. of Lumière's Hg and Ag intensifiers. This soln. is recommended for prints made on $AgCl$ papers. J. F. ROSS

Mercury printing. A. STEIGMANN. *Das Atelier* 32, 65-8(1925); cf. C. A. 19, 2306, 3436.—A method is described for making prints with Hg salts which give results similar to the dichromated gum process. Hg printing has the advantage in that it is possible to make 2 successive printings, one for the shadows and one for the halftones. The process consists in first coating the paper with a soln. for printing shadow detail, after printing and developing it is coated with a second soln. which is suitable for printing the halftones. The paper is then given a second exposure and development. The sensitizing soln. is essentially a mixt. of 1 part of 4-6% soln. of $HgCl_2$ and 2 parts of a 4% $(COOH)_2$ soln. The light-sensitiveness of this soln. is increased by addn. of increasing amts. of NH_4OH . The soln. used for shadow printing consists of 5 cc. of the sensitizing soln. and 3 drops of NH_4OH . For printing the halftones a mixt. of 5 cc. of sensitizing soln., 1 drop of $FeCl_3$ and 5 drops of NH_4Cl is used. Development and fixation are carried out immediately after exposure, without previous washing, by means of Lumière's Hg intensifier in daylight. The shadows develop in 15-20 min. and the halftones in about 10 min. The following developer is recommended: soln. A: 1000 cc. H_2O , 180 g. Na_2SO_3 and 75 cc. of a 5% soln. of $HgCl_2$; soln. B: 1000 cc.

H₂O, 20 g. Na₂SO₃, and 20 g. *p*-phenylenediamine (or 10 g. metol). For use 50 parts of soln. A are mixed with 5 parts of soln. B. J. F. ROSS

Enlarged positives or negatives direct. R. READE. *Amat. Phot.* **60**, 694(1925).—The method recommended consists in replacing the developed but unfixed Ag image by a U image, using this image as a negative and printing through this on to the unaltered emulsion beneath. The U image is removed by the alkali in the second developer, thus leaving a positive image. Working formulas are given. J. I. C.

The baryta coating of photographic papers. I. T. BENTZEN. *Phot. Ind.* **1925**, 783-5; cf. *C. A.* **19**, 1994.—Specific instructions are given for prepg. a baryta coating for photographic paper, with a method of testing the finished product. A typical coating contains 12 kg. of BaSO₄ (56%), 550 g. medium hard gelatin, 6500 cc. distd H₂O, 100 cc. 10% citric acid, 500 cc. denatured alc., 350 cc. 10% Cr₂(SO₄)₃ soln. mixed with 67 cc. glycerol and 100 cc. milk. M. L. DUNDON

The desensitizing action of mercuric salts. G. KÖGEL AND A. STEIGMANN. *Phot. Ind.* **1925**, 70(1925).—Hg salts desensitize AgBr gelatin emulsions strongly, but cannot be used as desensitizers in development because the effect is not sufficiently permanent. Negatives bleached with HgCl₂, washed and pressed against a Ag halide paper cause a selective desensitizing, so that when the paper is given a flash exposure and developed, a positive copy from the negative is produced. HgI also causes selective desensitizing but a negative, instead of a positive image results. M. L. DUNDON

A method for the intensification of a photographic image by mordanting dyes on the silver. A. AND L. LUMIÈRE, AND A. SEYEWETZ. *Rev. franç. phot.* **6**, 1-2(1926).—The image is bleached for 3-4 min. in: CuSO₄ 40, K₂C₆H₅O₇ H₂O 60, AcOH (glacial) 30, NH₄CNS, dissolved separately 20 g., water to make 1 l. After washing, the negative is immersed for 15 min. in a mixt. of: methylene blue, 1% 287 cc., Rhodamine D, 1% 333 cc., Phosphine M, extra concn., 1% 380 cc., washed in running H₂O for several min. and dried. O. W. COOK

Photographic emulsions. KODAK, LTD. Brit. 235,209, June 6, 1924. Increase of the sensitiveness of photographic emulsions formed of various colloidal substances is effected by incorporating in them substances such as are extd. from gelatin by standing for several days with H₂O in moderate excess over the quantity which is absorbed by the gelatin. PhOH may be added to prevent injurious bacterial action and the extn. may be effected at a temp. of about 30°. Brit. 235,210 specifies addn. to colloidal photographic emulsions of sensitizing material extd. from org. tissues such as hides, bones, cereal, grains and leguminous plant seeds, which may be obtained as by products of the treatment of hides or bones as in gelatin manuf., from deliming solns., etc. Numerous examples and details of procedure are given. Brit. 235,211 specifies the use, as sensitizing agents, of "any compd. contg. a bivalent atom of the S group joined by a double bond to a single non-metal atom to which at least 1 other group of atoms is attached." Even less than 10 grains of thiosinamine may be used with 130 lbs. of dry ingredients of the emulsion. Among the compds. which may be used are carbamide carbimides and their "sub-series" contg. alkyl, aryl, acyl, hydroxy, aryl-oxo, or other groups, allyl isothiocyanate, phenyl isothiocyanate, phenylthiourea, thiocarbanilide, Na₂S₂O₃, di-*o*-tolyl thiourca, allyl isoselenocyanate, thioacetamide, thioformamide, thioarbituric acid, telluro-mustard oils (allyl isotellurocyanate), K tellurocyanide and allyl tellurourea. Gelatins which are substantially inert may be rendered active by use of these compns.

Photographic pigmentary printing paper. J. SURY. U. S. 1,571,103, Jan. 26 See Brit. 216,860 (*C. A.* **19**, 18).

Waterproofing motion-picture films, etc. V. A. STEWART. U. S. 1,569,151, Jan. 12. Exposed and developed photographic film is subjected to the action of vapors which will render the colloid substances on the film insol. For this operation a film is wound in a roll with an intervening layer of open-textured fabric which permits penetration of the vapors between the convolutions of the roll.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

The stereochemical configuration of cobalt complexes with anomalous coördination numbers. KICHIMATSU MATSUNO. *J. Coll. Sci. Imp. Univ. Tokyo* **45**, No 8, 1-16(1925). (In English).—Co complex salts having coördination numbers greater than 6 are as follows: [Co(NH₃)₅C₂O₄]X, [Co(NH₃)₅CO₃]X, [Co(NH₃)₅SO₄]X, [Co(NH₃)₅-

SO_3X M discusses various theories of the configuration of these salts. According to Werner's hypothesis, when salts have coordination numbers greater than 6, if 8 atoms or atom groups combine directly with the central atom, they would take up the position of the 8 corners of a cube. This structure of a complex radical admits of 2 pairs of isomers each in optical antipodes. Werner's theory is tested out as follows. As the number of ions of cobaltamines is proportional to the cond. of the salts, the detn. of the mol. conductivities was carried out, in Ostwald's app. The results are tabulated. The mol. cond. of *pentammine-oxalato-cobaltic sulfate* is given as 86.78 at a diln. of 200, while that of *tetrammine-carbonatocobaltic sulfate* at the same diln. is 87.18, practically equal, which is evidence of the substitutional reaction: $[\text{Co}(\text{NH}_3)_5\text{C}_2\text{O}_4\cdot\text{SO}_4\cdot\text{C}_2\text{O}_4\cdot(\text{NH}_3)_3\text{Co}] + 2\text{H}_2\text{O} \longrightarrow [\text{Co}(\text{NH}_3)_5\text{C}_2\text{O}_4\text{H}_2\text{O}]_2\text{SO}_4$. The mol. conductivities of *pentammine-carbonato-cobaltic nitrate, iodide and bromide* at a diln. of 1600 are, resp., 221.3, 226.8 and 225.9, all greater than that of *tetrammine-oxalato-cobaltic chloride*, 136.5. These numbers correspond to the cond. of 2 ions rather than 3, therefore the substitution takes place thus: $[\text{Co}(\text{NH}_3)_5\text{CO}_3\text{X}] + \text{H}_2\text{O} \longrightarrow [\text{Co}(\text{NH}_3)_5\text{CO}_3\text{H}_2\text{O}]\text{X}$. From these results and data on *pentammine-sulfato-* and *sulfito-cobaltic salts*, the following type equation for the substitution is written: $[\text{Co}(\text{NH}_3)_5\text{X}''\text{X}'] + \text{H}_2\text{O} \longrightarrow [\text{Co}(\text{NH}_3)_5\text{X}''\text{H}_2\text{O}]\text{X}'$. The resolution of $[\text{Co}(\text{NH}_3)_5\text{C}_2\text{O}_4\text{SO}_4\text{H}]\text{H}_2\text{O}$ was effected by treatment with $\text{BaC}_4\text{H}_4\text{O}_6$, filtering out BaSO_4 , crystallizing the tartaric acid salts and eliminating the tartaric acid radical by adding BaCl_2 . *d-* and *l-Pentammine-oxalato-cobaltic chloride* were produced and gave $[\alpha]_{26}^{20}$, $+16^\circ$ and -16° . The resolution of $[\text{Co}(\text{NH}_3)_5\text{SO}_4\text{SO}_4\text{H}]\text{H}_2\text{O}$ also yielded 2 optically active isomers. The *absorption spectra* of these complexes were studied; the curves obtained from $[\text{Co}(\text{NH}_3)_5\text{C}_2\text{O}_4\text{X}]$ and $[\text{Co}(\text{NH}_3)_5\text{CO}_3\text{X}]$ are similar. The curves of $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{C}_2\text{O}_4$ and $[\text{Co}(\text{NH}_3)_5\text{C}_2\text{O}_4]\text{Cl}$ are of entirely different types, from which it is evident that the oxalato group of the second is attached to the central Co and the acid radical outside the first sphere of complex has no effect upon the light absorption. The absorption curves show further that the SO_4 radical coordinates symmetrically with Co while the SO_3 radical does so asymmetrically. All these facts are considered a strong verification of the theory that the configuration of these salts is cubic.

H. STÖRTZ

Oxidation of metallic iron by a current of air in presence of iron salts. PETER FIREMAN. *Ind. Eng. Chem.* **18**, 262-3(1926).—Some observations on the conversion of Fe into a hydrated ferric oxide show that it is expedited by blowing air through a bundle of metal strips suspended in a soln. of ferrous salt. There are marked changes in color during the transformation, particularly when a sulfate soln. has been used, and the reddish brown oxide is shown to be a monohydrate of ferric oxide. W H B

Formation and decomposition of the sodium complexes of platinum and iridium chlorides. LOTHAR WÖHLER AND PH. BALZ. *Z. anorg. allgem. Chem.* **149**, 353-8 (1925).—The disson. of the Na complexes with increasing temp. may be followed by detg. the pressure of free Cl_2 . In the disson. of the Na complex of PtCl_4 and PtCl_3 , the Cl pressure changes continuously with the Cl content of the residue; at a Cl pressure of 1 atm., the Cl content of the residue varies with the temp. Therefore, the dissociating complex forms a bivalent soln. with the disson. products. This behavior is the same as that of the metals, chlorinated in the presence of NaCl . The curves for these relationships show no break. By chlorination of the metals in the presence of NaCl or by disson. of the complexes the new *compds.* PtCl° , PtCl_3 and IrCl and IrCl_2 are obtained. The Na complex of PtCl_4 forms below 660° ; above 800° only the complex of the bivalent metal exists. The complex of IrCl_4 forms up to 570° , but over 800° only the complex of IrCl_3 exists in the melt. IrCl can be titrated in the presence of IrCl_3 in soln. of the complexes by means of $\text{Na}_2\text{S}_2\text{O}_8$; the end point is conveniently detd. electrometrically.

ROSALIE M. COBB

The complex compounds of the ruthenium chlorides. RAYMOND CHARONNAT. *Compt. rend.* **181**, 866-7(1925); cf. *C. A.* **19**, 2176.—C. believes that the coordination no. of Ru is 6 in the K chlororuthenites. He has prep'd. $[\text{RuCl}_6]\text{K}_3$ from $[\text{RuCl}_5(\text{OH})_2]\text{K}_2$ with HCl gas: orthorhombic plates, with 1 mol. of H_2O of crystn. The hitherto unknown $[\text{RuCl}_6]\text{Na}_3$ has been prep'd. by reduction with alc. of a dil. acid soln. of the brown chloride of Ru (Howe's method). If the addn. of alkali chloride is omitted there is obtained by concn. *in vacuo* $\text{RuCl}_3\cdot\text{HCl}\cdot 2\text{H}_2\text{O}$. Ru presents, in all, 5 chloro salts (I) $[\text{RuCl}_5(\text{OH})_2]\text{K}_2$, (II) $[\text{RuCl}_5(\text{OH})_2](\text{NH}_4)_2$, (III) $[\text{RuCl}_6]\text{K}_3\cdot\text{H}_2\text{O}$, (IV) $[\text{RuCl}_6](\text{NH}_4)_3\cdot\text{H}_2\text{O}$, (V) $[\text{RuCl}_6]\text{Na}_3\cdot 12\text{H}_2\text{O}$ analogous to the corresponding Rh and Ir salts.

M. O. LAMAR

Double sulfates and chromates of guanidine with the bivalent and trivalent metals. G. CANNERI. *Gazz. chim. ital.* **55**, 611-5(1925).—The double sulfates of guanidine $(\text{CN}_2\text{H}_5)_2\cdot\text{H}_2\text{SO}_4$ $\text{R}''\text{SO}_4\cdot 6\text{H}_2\text{O}$ (in which $\text{R}'' = \text{Mg}, \text{Zn}, \text{Cd}, \text{Fe}, \text{Ni}, \text{Co}, \text{Mn}$,

Cu and UO_2) were obtained by crystg. at room temp. solns. obtained by dissolving the component salts in equimol. amts. in the minimum amt. of H_2O . With the Fe salt it was necessary to protect the soln. against oxidation. Mixed crystals contg. 19.2% of the Zn and 80.8% of the Ni double salts were obtained as bright green crystals on evapg. mixts. of solns. of the 2 salts. Equimol. amts. of the component salts in soln. when mixed and evapd. spontaneously gave *magnesium guanidine double chromate*, $(\text{CN}_3\text{H}_5)_2 \cdot \text{H}_2\text{CrO}_4 \cdot \text{MgCrO}_4 \cdot 6\text{H}_2\text{O}$, isomorphous with the corresponding sulfate. The *chromium guanidine alum*, $(\text{CN}_3\text{H}_5)_2 \cdot \text{H}_2\text{SO}_4 \cdot \text{Cr}_2(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$, and *ferrous guanidine alum* were obtained similarly. Solns. of $(\text{CN}_3\text{H}_5)_2 \cdot \text{H}_2\text{SO}_4$, $\text{Cr}(\text{SO}_4)_3$ and $\text{Al}_2(\text{SO}_4)_3$ mixed and evapd. spontaneously sepd. mixed crystals contg. 21.6% $(\text{CN}_3\text{H}_5)_2 \cdot \text{H}_2\text{SO}_4$, $\text{Cr}(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$ and 78.4% $(\text{CN}_3\text{H}_5)_2 \cdot \text{H}_2\text{SO}_4 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$. A soln. of $\text{V}_2(\text{SO}_4)_3$ was prepd. by a method described in detail and when $(\text{CN}_3\text{H}_5)_2 \cdot \text{H}_2\text{SO}_4$ was added sepd. on spontaneous evapn. *vanadium guanidine alum*, $(\text{CN}_3\text{H}_5)_2 \cdot \text{H}_2\text{SO}_4 \cdot \text{V}_2(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$.

E. J. WITZEMANN

The double sulfates of the rare earth metals and of the alkaline metals. IV. Double sulfates of neodymium and sodium. F. ZAMBONINI AND G. CAROBBI. *Atti accad. Lincei* [6], 2, 374-7 (1925).—In continuing this study (Z. et al., C. A. 19, 2309, 2920; 20, 346) the system $\text{Nd}_2(\text{SO}_4)_3$ - Na_2SO_4 - H_2O was studied at 25°. Four compds. were obtained as follows: $\text{Nd}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ (I); $4\text{Nd}_2(\text{SO}_4)_3 \cdot 5\text{Na}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$ (II); $3\text{Nd}_2(\text{SO}_4)_3 \cdot 4\text{Na}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ (III); $2\text{Nd}_2(\text{SO}_4)_3 \cdot 3\text{Na}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$ (IV). These substances were all obtained as fine microcryst. pale rose-violet powders. I is stable in contact with solns. contg. 0.0-0.3% $\text{Nd}_2(\text{SO}_4)_3$ and 0.5-5% Na_2SO_4 . The field of existence of II is more limited, i. e., in solns. contg. 5.5-9% Na_2SO_4 . For III the compn. of the solu. may vary from 14 to 9% Na_2SO_4 and for IV from 15 to 17%. In the case of $\text{La}_2(\text{SO}_4)_3$ only one compd. $\text{La}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ is formed. E. J. WITZEMANN

Chromates of the metals of the cerium group. F. ZAMBONINI AND G. CAROBBI. *Rend. accad. sci. Napoli* [iii], 31, 17-24 (1925). The anhyd. chromates of La, Pr and Nd were obtained by heating intimate mixts. of the chlorides of these metals with K_2CrO_4 to temps. above 600°. A similar attempt to prep. anhyd. Ce chromate at 1000° resulted in the formation of a mixt. of Cr_2O_3 and CeO_2 . In addn. to the octahydrates of the above salts prepd. by Britton (C. A. 19, 19), the following new hydrates were prepd. by pptn. methods from cold solns. $\text{La}_2(\text{CrO}_4)_3 \cdot \text{H}_2\text{O}$, $\text{Nd}_2(\text{CrO}_4)_3 \cdot 10\text{H}_2\text{O}$, $\text{Pr}_2(\text{CrO}_4)_3 \cdot 10\text{H}_2\text{O}$, $\text{Sm}_2(\text{CrO}_4)_3 \cdot 9\text{H}_2\text{O}$. B. C. A.

Inorganic magnesyl derivatives. QUINTINO MINGOIA. *Gazz. chim. ital.* 55, 713-21 (1925).—Recently Oddo and Calderaro (C. A. 17, 2264) began the study of NH_2MgX obtained by passing NH_3 into an Et_2O soln. of EtMgI . This 1st example of an inorg. magnesyl deriv. used in org. synthesis suggested the prepn. of others to be used in both org. and inorg. synthesis. The work is to be extended in various directions. In this paper results obtained with HSMgX are described. EtMgBr was obtained as usual. A stream of pure dry H_2S was bubbled through the Et_2O soln. for 0.5 hr. in the cold and then 0.5 hr. with warming. A white ppt. sepd. and C_2H_6 was evolved. The gas evolved was passed through 10% NaOH in order to measure the C_2H_6 produced, and it was found that a mol. of H_2S liberates 1 mol. C_2H_6 . In H_2O *magnesyl sulfhydrate* (I) decomps. thus: $\text{BrMgSH} + \text{H}_2\text{O} \rightarrow \text{H}_2\text{S} + \text{MgBr(OH)}$. I in Et_2O reacts with quinoline giving the addition compd. $(\text{C}_9\text{H}_7\text{N})_2 \cdot \text{SHMgBr}$, which is decompd. by H_2O giving quinoline, H_2S and Mg(OH)_2 . The soln. of I treated with BzCl in Et_2O gives α -thiobenzoic acid. With AcCl , however, I reacts giving Ac_2S and not AcSH . An Et_2O soln. of EtOCOCl with I gives $(\text{Et}_2\text{OCO})_2\text{S}$ instead of EtOCOSH as was expected. With alkyl iodides I reacts giving the corresponding mercaptans. I reacts with AcH in Et_2O , giving a white ppt. from which trithioacetaldehyde, $(\text{CH}_3\text{CHS})_3$, m. 45-6°, was isolated. The primary product is MeCH(SH)OMgBr , which was isolated as the quinoline addition product, $\text{C}_{20}\text{H}_{14}\text{N}_2\text{MgOBr}$. I with isovaleraldehyde gives thioisovaleraldehyde, b. 114-5°.

E. J. WITZEMANN

Mixed basic silver-copper salts. G. MALQUORI. *Atti accad. Lincei* [vi], 1, 392-6 (1925).—Investigation of the system Cu(OH)_2 - AgNO_3 - H_2O at 20° indicates the existence of only 1 basic salt, $3\text{Cu(OH)}_2 \cdot 2\text{AgNO}_3 \cdot 3\text{H}_2\text{O}$, which is decomposed by H_2O but is stable in presence of AgNO_3 solns. having concns. not less than 0.78%. B. C. A.

Complex formation in lead nitrate solutions. II. The quaternary system: potassium nitrate-lead nitrate-barium nitrate-water. SAMUEL GLASTONE AND E. J. RIGGS. *J. Chem. Soc.* 127, 2846-54 (1925); cf. C. A. 17, 3844.—The ternary systems KNO_3 - $\text{Ba(NO}_3)_2$ - H_2O and $\text{Pb(NO}_3)_2$ - $\text{Ba(NO}_3)_2$ - H_2O were investigated at 25° and 50°. The system KNO_3 - $\text{Pb(NO}_3)_2$ - H_2O has previously been investigated (C. A. 17, 3844). Finally the quaternary system was studied at 25° and 50°. There is some evidence that a double salt $2\text{KNO}_3 \cdot \text{Pb(NO}_3)_2$, which has no sep. stable existence at room temp.,

exists in soln. and seps. as a mixed crystal with the known double salt $2\text{KNO}_3 \cdot \text{Ba}(\text{NO}_3)_2$.

The solid hydrides of arsenic, antimony and bismuth. R. J. WEEKS AND J. G. F. DRUCE. *Rec. trav. chim.* **44**, 970-4 (1925).—The solid hydride of As (As_2H_2) was found by Janovsky (*Ber.* **6**, 216 (1874)) and Reckleben and Scheiber (*C. A.* **5**, 2227) and Thoms and Hess (*C. A.* **15**, 1471) prepd. it by other methods. Moser and Bruhl (*C. A.* **19**, 20) obtained As_2H_2 by passing AsH_3 into a soln. of SnCl_2 in HCl . W. and D. confirmed this but could not obtain the corresponding compds. of Sb and Bi. W. and D. (*C. A.* **19**, 2310) obtained Sb_2H_2 but have now prepd. it thus: $2\text{SbCl}_3 + 8\text{H} \rightarrow \text{Sb}_2\text{H}_2 + 6\text{HCl}$ ($\text{Zn} + \text{H}_2\text{SO}_4 + \text{SbCl}_3$ in H_2O give Sb_2H_2 as a gray insol. ppt.). Sb_2H_2 is sol. in HNO_3 and when heated to redness reacts thus: $3\text{Sb}_2\text{H}_2 \rightarrow 4\text{Sb} + 2\text{SbH}_3$. BiH_3 was prepd. by Paneth and Winternitz (*C. A.* **13**, 1430, 1431) but Bi_2H_2 was unknown. BiCl_3 treated with $\text{Zn} + \text{HCl}$ gave Bi_2H_2 as a gray ppt.; decomp. when heated *in vacuo*, giving $\text{H} + \text{Bi}$. Sb_2H_2 and As_2H_2 heated *in vacuo* give $\text{H} +$ the metal and some SbH_3 and AsH_3 . If the hydrides are heated in a current of H and the gas is passed through AgNO_3 soln., Ag_3Bi , Ag_3Sb and Ag_3As , resp., are pptd. Heated in air As_2H_2 decomp. at about 45° , Sb_2H_2 at about 170° and Bi_2H_2 at a higher temp. E. J. WITZEMANN

Lead dihydride and lead tetrahydride. E. J. WEEKS. *J. Chem. Soc.* **127**, 2815-6 (1925).—To a soln. of alkali plumbite, pure Al was added. The gray ppt., lead dihydride, was washed with KOH soln. and water, then filtered and dried over H_2SO_4 in an atm. of H . The reaction follows the equation: $2\text{KHPbO}_2 + 2\text{Al} \rightarrow 2\text{KAlO}_2 + \text{Pb}_2\text{H}_2$. To obtain the tetrahydride, the dihydride was heated in a silica tube in an atm. of H , and the issuing gas deposited Pb in a heated tube. It is concluded that the dihydride was reduced according to the equation: $\text{Pb}_2\text{H}_2 + 3\text{H}_2 \rightarrow 2\text{PbH}_4$.

R. J. HAVIGHURST

The constitution of chloride of lime. BERNHARD NEUMANN AND FREDERICK HAUCK. *Z. Electrochem.* **32**, 18-31 (1926).—All previous attempts to det. the constitution of chloride of lime have failed on account of the impurities in the materials used. In Odling's formula, ClCaOCl , the ratio of OCl to Cl is equal to 1. In pure, fresh chloride of lime there is never any free Cl . The ratio of the chlorinated lime to the unchlorinated portion is a practically const. ratio of 3 to 1. In the sunlight, an intramolecular change takes place according to the equation: $6\text{CaOCl}_2 \rightleftharpoons 5\text{CaCl}_2 + \text{Ca}(\text{ClO})_2$. If freshly prepd. chloride of lime is completely freed from adhering Cl_2 with dry N_2 , air or CO a chloride of lime is obtained with an always reproducible Cl_2 content of 39.0%, which is the highest attainable amt. The ratio of the chlorinated lime to the unchlorinated is always found to be 3:1. Hence, the chloride of lime must exist as a basic salt, $3\text{ClCaOCl} \cdot \text{CaO}$. The optimum chlorination is reached when the hydrated lime contains 3.75% excess H_2O . Moist CO_2 reacts with chloride of lime to form CaCl_2 . It can be shown that the existence of CaCO_3 in the chloride of lime is sufficient to cause the formation of CaCl_2 and to cause the complete transformation of the bleaching Cl_2 into CaCl_2 . It is not possible to chlorinate all the hydrated lime even if the chlorination is carried out under pressure. Some chlorate and chlorite are formed. By heating chloride of lime in the presence of air to around 60° , the formation of chlorate is started, the rate of formation being most rapid between 70° and 80° ; above 85° , decomposition occurs. By chlorination, in the absence of air at 65° to 70° , increasing amounts of chloride and chlorate are formed, which are always obtained in the ratio of 5 to 1. This is evidence that these products originate only through the intramolecular change $6\text{CaOCl}_2 = 5\text{CaCl}_2 + \text{Ca}(\text{ClO})_2$. Odling's formula is proved by heating pure chloride of lime, in the absence of air, to 70 - 80° , from which there is obtained a complete transformation into CaCl_2 and $\text{Ca}(\text{ClO})_2$ and in the ratio of 5 to 1. The formula for pure chloride of lime is concluded to be $3\text{ClCaOCl} \cdot \text{CaO} \cdot 6\text{H}_2\text{O}$.

J. H. PERRY

The preparation of beryllium. ALFRED STOCK, PAUL PRAETORIUS AND OTTO PRIESS. *Ber.* **58**, 1571-80 (1925).—Previous efforts to obtain Be in a pure condition by electrolytic methods were unsuccessful. The authors' method is based upon the electrolysis of Be salts at such a temp. that the metal will sep. in a liquid, and therefore compact, form. Crude oxide is used as a raw material. Digest 100 g. under a reflux condenser with 0.75 l. concd. HCl . Evap. the soln. in a porcelain dish at 130 - 140° with const. stirring. Cool and dil. the viscous residue of basic chloride to 1 l. Pour slowly into a mechanically agitated soln. of 2000 g. Na_2CO_3 in 9 l. H_2O , at the same time conducting a rapid stream of CO_2 into the soln. The NaHCO_3 formed dissolves the greatest part of the basic Be carbonate at first formed, while Al and Fe remain insol. as oxyhydrates. Continue this for 12 hrs., then let the liquid stand for 24 hrs. in tall cylinders, siphon off the soln. and discard the ppt. To remove the small amt. of Fe still present treat with H_2S , filter after several days and carefully add HCl to the

filtrate to form a basic carbonate, contg. the greatest part of the Be and still considerable alkali. Wash the ppt. with H_2O and then covered with H_2O in a 5-l. flask, heat, and carefully add HCl until a permanent red color is obtained with methyl red, steam being passed in until the mix is near boiling. Filter the residue, wash with H_2O until free from Cl and dry at 150–160°. The material obtained contains 55–65% BeO, not more than a trace of alkali, about 0.1% Al_2O_3 and traces of Fe_2O_3 . Dissolve the theoretical quantities of $Be(OH)_2$, pure Na_2CO_3 and pure $BaCO_3$ to give $NaBeF_3$, $BaBeF_4$ and $BaBe_2F_6$ in pure HF in a Pt dish, evap. to dryness over a small flame and heat to fusion. $NaBeF_3$ melts at about 500° and vaporizes strongly at 900°, $BaBeF_4$ melts over 1000° and vaporizes considerably at 1150°, while $BaBe_2F_6$ melts at about 900° and vaporizes appreciably at 1100°. To contain the electrolyte and serve as anode use an Acheson graphite crucible; use a H_2O -cooled Fe cathode. Heat the crucible to 700–800°, add 150 g. powdered $NaBeF_3$, immerse the cathode, add slowly 150 g. $BaBeF_4$ and raise the current to 60 amp. When 1350° has been attained, remove the cathode, clean it with a wire brush and again immerse, regulating the current to hold 1350°. About every 4 min., add 10 g. of $BaBe_2F_6$ until a total of 420 g. is reached. After 3 hrs. stop the current and remove the cathode. The Be adheres to it but is easily removed; again immerse the cathode in the electrolyte. Add 75 g. $NaBeF_3$ and 10 g. $BaBe_2F_6$ every 4 min., and continue the electrolysis for 3 hrs. as before. Repeat still again; the total yield of Be is 47–55 g., a yield of 38–44%, with an energy consumption of 60 kw. hr. The Be obtained was freed of slag and oxide by immersing in fused alkali chlorides and then washing with H_2O , alc. and ether, and cleaning with emery paper. It contains no oxide inclusions and shows a bright cryst. fracture. It is very stable, remaining unaffected for a year in a loosely stoppered flask. It is darkened slightly by heating with a blast lamp; it scratches glass but is polished by emery. Its d is 1.842 at 18°. The purity was detd. by measuring the vol. of H_2O liberated on treatment with HCl. Al was detd. colorimetrically by the formation of an alizarin lake which is removed by centrifuging, dissolved in NaOH and compared with a standard. This method proved reasonably accurate in the presence of large quantities of Be. If Fe is present it is included in the Al detn., but can be estd. separately by formation of a thiocyanate and comparing this colorimetrically with a standard. H. S.

Preparation of pure titanium, zirconium, hafnium and thorium metal. A. E. VAN ARKEL AND J. H. DEBOER. *Z. anorg. allgem. Chem.* **148**, 345–50 (1925).—These metals prepd. by reducing pure tetrachloride with Na and treating with H_2O and then HCl always contain traces of oxide and nitride. Electrolysis of the double fluoride produces no better results. The authors tried the following method. A W filament is heated to glowing in a mixt. of H and tetrachloride vapor. Only a very small deposit was found on the filament and it consisted of a mixt. of nitride, carbide and oxide rather than metal. This was due to impurities in the H_2 . It was found impossible to eliminate all of these. The method, however, is useful for prepg. compds. of the metals, such as carbides, nitrides and sulfides. A requisite condition for prepg. the metals is that a temp. exists below the m. p. of the metal at which its vapor pressure is smaller than the partial pressure of the metal in the gas phase. Since iodides dissociate at lower temp. than chlorides, the following method was used. A W filament is heated to 2000° in the tetraiodide vapor in a glass chamber kept at 650°. A layer of 2–4 mm. of metal can be deposited under these conditions in a few hrs. and is found to be very pure. Zr obtained by this method is extraordinarily ductile and flexible, similar to Cu in these properties. It can be hammered or drawn into wire without difficulty. This is not a different modification from ordinary Zr, but is hexagonal and has the same lattice const. as Zr prepd. by any other method. By the same method, Hf, Hf-Zr alloys, Ti and Th can be prepd., both Th and Ti being very ductile. Hf shows high m. p., high sp. gr. and high electron emission. The authors state that Fischvoigt and Koref could not have obtained pure metals by their method. H. STOERTZ.

Metallic uranium. J. F. GOGGIN, J. J. CRONIN, H. C. FOGG AND C. JAMES. *Ind. Eng. Chem.* **18**, 114–6 (1926).—By carrying out the reaction between UCl_4 and Ca (10% excess of the latter) in an Al_2O_3 crucible placed in an elec. heated bomb which is contained in a vacuum chamber, the metallic U is obtained as a fused mass. With the use of ordinary "pure" Ca the U contained 0.57% Fe, 0.09% C, 0.03% O, trace Al and no Ca or Si, but by the use of resublimed Ca the Fe content could be reduced to less than 0.01%. The prepn. of UCl_4 from UO_2 by the action of Cl_2 and S_2Cl_2 is also described. W. B. PLUMMER •

Preparation of metal tellurides from hydrogen telluride and solutions of salts. A. BRUKL. *Monatsh.* **45**, 471–84 (1925).—A no. of tellurides of the metals have been prepd. by pptn. of solns. of salts with H telluride or, in certain cases, with Na telluride

soln. The compds. PdTe, Cu₂Te, PbTe, BiTe, NiTe, CoTe, As₂Te₃ are described in greater detail than hitherto; the following tellurides have been isolated for the first time: *mercuric, auric, ferrous, stannous, stannic, antimonious, thallous and platinic*. Most of these compds. are unstable in air and tend to reduce solns. of substances such as mercuric or cupric salts. They are sol. in dil. acids with the exception of the Pb, Ni, Co, Au, Pt, As and Sb tellurides. There is in all cases a progressive deepening of color from the sulfide to the selenide and the telluride. B. C. A.

The thermal decomposition of alkali perborates. H. MENZEL, J. MECKWITZ AND W. KRETSCHMAR. *Oesterr. Chem.-Ztg.* **28**, 162-3(1925).—Alkali perborates were made by the action of H₂O₂ on the corresponding monoborates and then—except with the Na salt—the addition of alc. A distinction is drawn between true perborates, which yield I₂ or develop O₂ with concd. KI soln. and pseudoperborates with H₂O₂ present in the role of "H₂O₂ of crystn." Difficultly sol. pseudo-NaBO₂·H₂O₂·3H₂O may be dried almost to NaBO₂·H₂O₂, and at a higher temp. *in vacuo* forms NaBO₂, which evolves O₂ rapidly with H₂O. This labile O is written (NaBO₂)₂·O₂. LiBO₂·H₂O₂·H₂O is described as a new compd. of the pseudo class. It may be dried to LiBO₂·H₂O₂; with H₂O or when heated to 250° it behaves like the Na salt. KBO₂·0.5H₂O is always obtained as a mixt. of the true and pseudo forms; it loses most of its H₂O in a vacuum between 100° and 200°, becomes yellow to brown, and its O goes into a labile form. NH₄BO₂·0.5H₂O acts as a true perborate. It does not give up H₂O completely below 100°. In a vacuum at 120° it decomposes with almost explosive violence. If heated carefully under a suction pump it gives up active O and NH₃. If the reaction occurs in evacuated, sealed vessels about 50-55% of the O, N and NH₃ remain in the gaseous phase; the remainder of the O is used to oxidize NH₃ to free N₂ and HNO₂. W. C. E.

The action of silica on electrolytes. II. A. F. JOSEPH AND H. B. OAKLEY. *J. Chem. Soc.* **127**, 2813-8(1925); cf. C. A. **18**, 6.—The action of an alk. hydroxide on pure silica results in the formation of a solid silicate, part of which passes into soln. In accordance with the solubilities of the silicates concerned, the amt. of solid silicate is very small with Na and K hydroxides, about 30% with Ba and nearly 100% with Ca. In the case of Na and K, the amt. of solid silicate produced is roughly proportional to the amt. of silica used, although the amt. of silicate in soln. is only slightly affected. This proves that the solid phases (silica and silicate) are directly concerned in the equil. The addn. of a neutral salt increases considerably the amt. of solid silicate formed. R. J. HAVIGHURST

The chemistry of phosphorus. I. Colorless phosphorus. LUDWIG WOLF AND KÄTHE RISTAU. *Z. anorg. allgem. Chem.* **149**, 403-12(1925).—An improved, whole glass app. is described for purification of P with an arrangement to carry out reactions under exclusion of air, moisture and fatty impurities. An app., for prepn. of pure *nitrogen* with the aid of TiN₂ (950-1000°) is also attached for carrying out reactions under pressure. The principle of the purification is repeated fractional distn. Recrystn from benzene is also used. The P modification m. 44.1° distils and is sol. in CS₂ with out residue. Only this should be called *colorless P*. JOHN T. STERN

The action of gaseous ammonia on phosphorus chlorides. H. PERPÉROT. *Bull. soc. chim.* **37**, 1540-8(1925).—See C. A. **20**, 348. E. H.

7—ANALYTICAL CHEMISTRY

WILLIAM T. HALL

Thiocyanogen and its application in volumetric analysis. H. P. KAUFMANN. *Arch. Pharm.* **263**, 675-721(1925).—An address descriptive of early and recent expts. looking to the isolation and study of free (SCN)₂ with respect to its chem. and phys. properties. For purposes of titrimetric application, based on its power to liberate I quantitatively from iodides, solns. of the reagent were prepd. by utilizing the behavior of Pb(OAc)₄ toward HSCN, namely, Pb(OAc)₄ + 2HSCN = Pb(OAc)₂ + (SCN)₂ + 2AcOH. Because of its tendency to polymerize and hydrolyze, expts. are described showing the relativest ability of (SCN)₂ in various org. solvents such as CS₂, CCl₄, Et₂O, MeOH and AcOH. The rhodanometric analysis of fats and oils was studied, as well as the addn. of (SCN)₂ to unsatd. fatty acids and glycerides. W. O. E.

The use of bromate in titrations, with special attention to the indicator question. OSCAR COLLENBERG. *Tids. Kemi Bergvaesen* **5**, 220-4, 239-43(1925).—A careful

study was made of the various factors affecting the decolorization of methyl orange in HCl solns. by a slight excess of KBrO_3 . From many expts., the following conclusions were drawn: The KBrO_3 titration should be carried out at 40–65°. In 100 cc. of soln. which is 0.36–1.6 N in HCl the decolorization is accomplished in 5 sec. as soon as 0.1 mg. in excess of KBrO_3 is present. At 40° the HCl concn. should lie between 0.5 and 1.7 N , provided 10 cc. or less of 0.1 N KBrO_3 is used in the titration. When more KBrO_3 is required, the concn. of the HCl should not exceed that of a normal soln. When less than 1.5 milli-equivs. of KBrO_3 are used, the titrated soln. should have a vol. of about 100 cc. but greater diln. is advisable with solns. contg. more of the oxidizable substance. No other indicator was found better than methyl orange. C. A. R.

Determination of the nitrate ion. K. KURSCHNER AND K. SCHARER. *Chem.-Ztg.* **49**, 1077–8(1925).—In agricultural chem. labs. the methods of Ulsch, of Arnd and of Devarda are used mostly for the detn. of N present as nitrate. The following method gives results which agree well with those of these methods. To not over 0.5 g. KNO_3 in a Kjeldahl flask, add a little water, a roll of Fe wire (such as is used for the standardization of KMnO_4) weighing 3.5 g., 0.5 g. of powd. CuO and 30 cc. of 12 N H_2SO_4 . Let stand an hr. at room temp., then heat for 30 mins. Finally cool, add an excess of NaOH and distil off NH_3 in the usual way. W. T. H.

Testing bicarbonate of soda. E. ISNARD. *Ann. fals.* **18**, 595–7(1925).—From a comparison of the tests prescribed in various pharmacopeas for the detection of NaHCO_3 I. concludes that the tests prescribed in the French Codex are valueless and suggests replacing them by the Moreau test (addn. of excess of standard NaOH and titration of the excess) and detn. of total Na_2O by titration with standard acid in presence of helianthine. A. PAPINEAU-COUTURE

Calculation of probabilities applied to sampling (of packaged materials). L. VALLERY. *Ann. fals.* **18**, 597–605(1925).—V. shows mathematically that with shipments of less than 200 packages the no. of packages which should be sampled are appreciably higher than what is generally considered sufficient, while with over 250 packages it tends to a limit. When the quality or compn. of the contents of each package, as well as the av. of the whole shipment, must meet given specifications, the samples from the different packages must be grouped into a no. of composite samples which should be analyzed separately, according to the tolerances and accuracy of the detns. This is also discussed mathematically. A. PAPINEAU-COUTURE

Methods and apparatus for chemical analysis with X-rays. R. BERTHOLD. *Z. angew. Chem.* **38**, 1188–91(1925).—The application of X-ray spectroscopy to quant. chem. analysis is described. R. J. HAVIGHURST

A simple quantitative method for the determination of cholesterol. L. SURÁNYI AND A. KORÉNYI. *Biochem. Z.* **160**, 178–82(1925).—To 0.1 cc. of a soln. of cholesterol in 96% EtOH add 0.1 cc. H_2O . Then add EtOH soln. until the pptd. cholesterol is redissolved. A table is presented showing the relation between the cholesterol present and the amt. of EtOH soln. necessary to effect soln. of the cholesterol under the above conditions. This scheme may be used in the detn. of cholesterol. F. A. CAJORI

A light filter for polarimetry (SCHOORL) 2.

The method of Spring applied to the problem of the diamond. L. DUPARC AND P. KOVALEFF. *Compt. rend. soc. phys. hist. nat. Genève* **41**, 108–12(1924); *Mineralog. Abstracts* **2**, 523.—Equil. relations between the diamond and graphite are discussed with the conclusion that the stability of the diamond increases with pressure and diminishes with temp. CS_2 and a metal with strong affinity for S were subjected to 8000 atm. pressure for 15 min. On dissolving the metal in acid a min. residue of colorless irregular

grains 0.5 mm. across remained. They were birefringent with high refraction and readily scratched glass but after a few days became covered with an opaque crust and fell to a fine powder. The suggestion is that diamond was formed in the expt. J. F. S.

Native sulfur in the coast zone of southwest Africa. E. RØUNING. *Centr. Mineral. Geol.*, A 1925, 86-94.—The nature and relations of the deposits are described. Conclusion: The S developed mainly in quiet water in closed basins or lagoons, in the presence of decaying org. matter. Bacteria assisted in the process. J. E. GILL

The crystal structure of α and β cadmium sulfide and wurtzite. F. ULRICH AND W. ZACHARIASEN. *Z. Krist.* 62, 260-73 (1926).—The dimorphism of CdS is entirely analogous to that of ZnS. Greenockite (α CdS) is hexagonal, C_{6v}^{4-} , with $a = 4.142$ and $c = 6.724$ A. U. Xanthochroite (β CdS) is cubic, zincblende type, with $a_0 = 5.820$ A. U. The unit cell for wurtzite (hexagonal ZnS) has the dimensions $a = 3.836$ and $c = 6.277$ A. U. I. S. RAMSDELL

Etch experiments on chalcopyrite from Botes. L. TOKODY. *Földtani Közlemény* (Budapest) 1924, 53 pp., 34-42 (Hung.). 126-8 (German); *Mineralog. Abstracts* 2, 500.—Crystals of chalcopyrite were etched with H_2SO_4 , HNO_3 and HCl, aqua regia and concd. solns. of NaOH and Na picrate. The etch-figures conform with the symmetry of the tetragonal-scalenohedral class. The action of acids is quite rapid. After etching, the faces show no luster except on the negative sphenoids where the action is slowest. J. F. SCHAIRER

The behavior of a mineral of the salt deposits under high pressure at changing temperatures, from researches by A. Geller. O. MÜGGE. *Nachrichten Ges. Wiss. Göttingen* 1924, 207-17.—The flow-pressures of halite, sylvite, bischofite, carnallite and mixed crystals of KCl and NaCl at several temps. were detd. The m. p. curves of kainite, bischofite and carnallite at various pressures were also detd. These detns. are applicable in an interpretation of the geological history of salt deposits in depth. J. F. SCHAIRER

Pseudomorphs of quartz after apophyllite and mesolite, in the vicinity of Kalageran. A. A. TVALCHRELIDZE. *Bull. Univ. Tiflis* No. 2, 148-55 (1922); *Mineralog. Abstracts* 2, 526.—Pseudomorphs of chalcedony, heulandite, celadonite, laumontite, stilbite, mesolite and quartz after apophyllite are found in geodes in weathered porphyryite. A mean of 4 analyses of mesolite gave SiO_2 44.40, Al_2O_3 25.63, CaO 10.97, Na_2O 5.02, H_2O 13.93, sum 99.95%; formula $(Ca, Na_2) Al_2 Si_3 O_{10} \cdot 3H_2O$. Large white heulandite crystals showed the presence of Sr. J. F. SCHAIRER

Analytical-synthetic studies of zincite. E. DITTLER. *Z. anorg. allgem. Chem.* 148, 332-44 (1925).—Analyses of the deep red zincite from Franklin Furnace, N. J. show the presence of Mn and Fe. Mixts. of ZnO with oxides of Mn were heated and crystd. D. concludes that the red color is due to only traces of a manganite. J. F. S.

Wad from the Waderalpe, Tyrol. E. DITTLER. *Centr. Mineral. Geol.*, A 1925, 101 5.—Analyses of specimens from 2 neighboring occurrences are given. The ratios of $MnO_2:MnO = 15:1$ and $11:1$. The impurities are limonite, barite and carbonates. J. E. GILL

Theories on the constitution of natural silicates. G. N. RIDLEY. *Chem. News* 131, 305-8 (1925).—R. reviews different theories, and favors that of W. and D. Asch, that silicates contain 10- or 12-membered rings of alternate Si or Al and O atoms. Classifying them into anhydrosilicates and hydrosilicates dispenses with uncertain details concerning the functions of Al_2O_3 and SiO_2 . The anhydrosilicates are less reactive, harder and probably of a coarser mol. texture. M. O. LAMAR

Rock-forming pyroxenes and zeolites from Mt. Tzkhra-Tzkhro in Trans-Caucasia. N. N. SMIRNOV. *Works Min. Inst. Moscow Univ.* 1923, 1-47; *Mineralog. Abstracts* 2, 527.—Measurements on 19 crystals of pyroxene found in coarse-grained andesite gave $a:b:c = 1.0925:1:0.5911$; $\beta = 74^\circ 13.5'$; $\gamma:c = 38-45^\circ$. Two analyses are given. Analyses of analcite, natrolite and mesolite, fresh and altered, are given. The zeolites have been derived from the labradorite of the rock by post-volcanic action of (1) H_2O alone, giving analcite + mesolite + heulandite, or analcite + laumontite; (2) H_2O + CO_2 , giving analcite or natrolite + calcite + free SiO_2 + $Al(OH)_3$; (3) H_2O and SiO_2 , giving analcite + heulandite, natrolite + heulandite, or all 3. J. F. S.

The relation of neptunite to the pyroxene group. B. GOSSNER. *Centr. Mineral. Geol.*, A 1925, 73-7.—Neptunite, $[SiO_2.SiO_3Na_2.TiO_3Fe].2SiO_2$, is a member of the alk pyroxene group, differing from aegerine in that all the Fe_2O_3 is replaced by $FeTiO_3$. Al_2O_3 and Fe_2O_3 enter to form mixed crystals to only a slight degree. G. emphasizes the value of resolving the bulk compn. of silicates into smaller complexes and considering them as double compds. as a method for disclosing relationships between different silicates. J. E. GILL

Mineral deposits in the serpentine of the Fichtelgebirge. H. LAUBMANN. *Centr. Mineral. Geol.*, A 1925, 79-86, 106-13.—The origin of the serpentine is discussed. Descriptions of various minerals and their occurrence in the serpentine and intrusive gabbro are given. New analyses of *vesuvianite*, *prehnite*, *chanozoisite* and *garnet* are included.

J. E. GILL

Kossmatite, a new member of the brittle-mica group and its paragenesis. O. H. FERDMANNSDORFFER. *Centr. Mineral. Geol.*, A 1925, 69-72.—A dolomitic marble in western Macedonia yields a mineral whose formula is calcd. to be $\text{Si}_2\text{O}_4\text{Al}_6\text{Mg}_3\text{Ca}_7\text{H}_{18}\text{F}$. It is believed that corundum \rightarrow diaspore \rightarrow kossmatite \rightarrow Mg-Al silicate constitute a reaction series with falling temp.

J. E. GILL

The formation of natural aluminium hydrosilicates. ROBERT SCHWARZ AND RUDOLPH WALCKER. *Z. anorg. allgem. Chem.* 145, 304-10(1925).—By means of the reaction between various Al salts with Na silicate in acid soln. it is shown that a p_{H} 4.8-5.0 is necessary to obtain an Al hydrosilicate in which the ratio $\text{Al}_2\text{O}_3:\text{SiO}_2$ is 1:2. The formation of kaolin (which has $\text{Al}_2\text{O}_3:\text{SiO}_2$ 1:2) from feldspars takes place only in those regions where this p_{H} 4.8-5.0 prevails. Values for CO_2 -saturated distd. water of p_{H} 3.8 at 20° and p_{H} 4.2 at 70° are given.

W. H. STRAIN

Beidellite, a new mineral name. E. S. LARSEN AND E. T. WHERRY. *J. Wash. Acad. Sci.* 15, 465-6(1925).—Restricting the name *leverrierite* as a species name to vermicular material with the $\text{Al}_2\text{O}_3:\text{SiO}_2$ ratio 1:2, a compact-cryst. compd. with a 1:3 ratio from Beidell, Colo. previously described under that name (C. A. 11, 1806) is now named *beidellite*. It is probably orthorhombic, and belongs to a mineral group lying, with respect to the Al-Si ratio, between the kaolinite and the pyrophyllite groups.

(cf. following abstr.)

L. W. RIGGS

Chemical composition and optical properties of beidellite. C. S. ROSS AND E. V. SHANNON. *J. Wash. Acad. Sci.* 15, 467-8(1925); cf. preceding abstr.—Analyses and optical data are reported of beidellite or closely related minerals from 4 localities. As Fe replaces the Al the *ns.* increase.

L. W. RIGGS

Mineralogical notes from the collections of the public museum of natural history of Genoa. A. D'AMBROSIO. *Ann. Mus. Civ. Stor. Nat. Genova* 51, 249-56(1924); *Mineralog. Abstracts* 2, 521.—(1). *The barettite of Traversella*—Two analyses of a green, radially-fibrous material with the external appearance of the barettite of L. Bombicci (1868) show no Ca (CaO 33.665% in the original analysis) and are mixts. of serpentine and brucite. (11). *Traversella, new variety of chrysocolla from Arenas in Sardinia*—This forms bright blue amorphous masses and ranges from compact to porous. Analyses gave

	SiO_2	Al_2O_3	CuO	CaO	H_2O	Sums
I	21.04	21.84	21.72	2.28	32.84	99.72
II	5.04	38.36	5.08	19.08	32.08	99.64
III	8.20	38.32	5.99	13.80	33.56	99.87

The variation in compn. is explained by admixture of chrysocolla and gibbsite.

J. F. SCHAIRER

The phosphate minerals and ores of the Amberg-Auerbach deposits. A contribution to the knowledge of Bavarian mineral deposits. H. LAUBMANN. *Geognostische Jahreshefte, Geol. Landesunters. München* 35, 193-204(1922); *Mineralog. Abstracts* 2, 522.—The Fe ore of Amberg and Auerbach, Bavaria consists of limonite contg. about 2.20% P_2O_5 . Wavellite, apatite, vivianite, cacozenite, beraumite, duferenite and the new species *weinschenkite* and pseudo-wavellite (cf. Henrich and Hiller, C. A. 17, 706) are found in the limonite. *The weinschenkite*, (Er, Yt) $\text{PO}_4 \cdot 2\text{H}_2\text{O}$, forms brilliant white radiating encrustations on limonite. It is monoclinic; partial crystallographic data are given. Its $n =$ about 1.6, birefringence about 0.03⁺. *Pseudo-wavellite* forms white radiating encrustations on limonite or wavellite. The colorless needles have triangular cross-section, and perfect basal cleavage. It is uniaxial + with $n =$ about 1.63, birefringence about 0.015. Analyses by Kieffer gave: Al_2O_3 28.18, (Yt_2O_3 , Er_2O_3) 1.02, Fe_2O_3 5.79, CaO 16.86, BaO 0.67, P_2O_5 30.10, H_2O 18.76, sum 101.38%.

J. F. SCHAIRER

The relationship between lautarite and dietzeite. B. GOSSNER. *Centr. Mineral. Geol.*, A 1925, 101-3.—Dietzeite is believed to be $\text{CaCrO}_4 \cdot \text{CaI}_2\text{O}_6$ instead of $8\text{CaCrO}_4 \cdot 7\text{CaI}_2\text{O}_6$ as held by Dietze. Any variation from the 1:1 proportion is accounted for by limited miscibility with lautarite (CaI_2O_6). Crystallographically these minerals are closely similar.

J. E. GILL

Genesis of sulfide ores. HORACE FREEMAN. *Eng. Mining J.-Press* 120, 973-5 (1925).—The reactions of alkali sulfides with those of the alkali earth metals and heavy

metals offer an explanation of the mode of formation of primary sulfide ore deposits and associated non-metallic minerals. The following fusing points were determined in the electric furnace: PbS 1130° , FeS 1000° , ZnS 1650° , Cu_2S 1100° , $\text{PbS} \cdot \text{Na}_2\text{S}$ 650° , $\text{FeS} \cdot \text{Na}_2\text{S}$ 660° , $\text{ZnS} \cdot \text{Na}_2\text{S}$ 620° , $\text{Cu}_2\text{S} \cdot \text{Na}_2\text{S}$ 560° . The melts have low viscosities and high sp. gr. Sulfates and carbonates of the alkaline earth metals (gang fillings) are formed by hydration, carbonation or oxidation of the sulfides of these metals. Colloidal silica is obtained from $\text{Na}_2\text{S} \cdot \text{SiO}_2$ by oxidation of the Na_2S . Hydrolysis of the double sulfides ppts. colloidal sulfides. Diffusion, osmotic pressure, gravity and differential soly. explain the differentiations. J. F. SCHAIERER

Alkaline sulfides as collectors of metals. J. R. SPURR. *Eng. Mining J.-Press* 120, 975-7 (1925).—A review of some geological facts with substantiating chem. evidence for theories of sulfide ore deposition. S. concludes that H_2O was not the universal solvent of ore magmas, F and B were not the principal carriers, and that the formation of double sulfides of heavy metals with alkali metals followed by hydrolysis and deposition of the heavy metal sulfides is a possible explanation of sulfide ore deposits. J. F. SCHAIERER

The role of colloidal solutions in the formation of mineral and metalliferous deposits. RENÉ VAN AUBEL. *Rev. gen. sci.* 36, 671-80 (1925).—This review considers (1) nature and localization of the colloidal minerals, (2) structure of the colloidal minerals of the deposits, and (3) the colloidal solus. and certain classic mineralized deposits. This last topic is developed under 16 sub-topics. Apparently the theory of colloidal solns. gives a working hypothesis for further study of the deep deposits. L. W. R.

The Tre Monti manganese mines above Sestri Levante. GAETANO CASTELLI. *Russ. min. met. chim.* 63, 101-13 (1925).—The Mn ore is of chem. sedimentary origin and occurs in phthamite-jasper formations accompanying serpentine rock. It may be classified in 4 chief com. types which contain: MnO_2 48.98-66.20, SiO_2 41.14-26.00, Fe_2O_3 3.01-1.52, Al_2O_3 1.45-3.35, CaO 4.50-2.00, MgO 0.38-0.38, P 0.05-0, H_2O at 100° 0.35-0.35%. The geology, methods of exploitation and equipment and valuation of the properties are described in detail. C. C. DAVIS

A manganiferous deposit at Monte Aquilaia, Province of Grosseto. L. SANNA. *Russ. min. met. chim.* 63, 129-30 (1925).—The ore is probably a mixt. of braunite, manganite and limonite. C. C. DAVIS

Report on the Batavia gold fields. P. A. WAGNER AND W. O. C. ROSS. *South African J. Ind.* 8, 543-64 (1925).—Au is distributed throughout a bed of conglomerate which is thin and of low or very erratic Au content. J. F. SCHAIERER

The geology and ore deposits of Mt. Stewart, Leadville, N. S. W. T. L. WILLAN. *Proc. Australasian Inst. Mining and Metallurgy* 1925, No. 47, 27 pp.—Ag was carried by hot ascending solns. of $\text{Fe}_2(\text{SO}_4)_3$ and deposited by cooling, H_2S and sulfides. There is a genetic relation between the ores and an intrusive granodiorite. Analyses of the Ag, Pb, Fe, Cu and Zn ores are included. The main ores are pyrite, Pb carbonates, Zn sulfide, chalcopyrite and a mixed Zn-Pb sulfide ore. Ag and Au in the pyrite are obtained as by-products in the utilization of the pyrite for H_2SO_4 manuf. J. F. S.

Chemistry of deposition of native copper from ascending solutions. R. C. WELLS. U. S. Geol. Survey, *Bull.* 778, 69 pp. (1925).—About 180 expts. are described with sufficient detail for reproduction in a well-appointed lab. The leading topics are: the reactions of Cu and of its compds., especially sulfides, sulfates and chlorides, with other elements and compds. associated with the Cu ores of the Lake Superior region, soly. of Cu and its compds. under varying conditions, transportation and pptn. of Cu, formation of native Cu through oxidation of S by ferric compds., equil. studies with Fe_2O_3 , Cu_2S and acid, and the reaction of Cu compds. on each other. The theories to account for the deposition of native Cu from ascending solns. are: (1) by cooling, (2) diln., (3) fractional oxidation of Cu_2S , and (4) neutralization and reduction. The 3rd theory appears to fit the Lake Superior district best in that the sp. influence of Fe_2O_3 in the rocks is taken into account in detg. the character of the Cu mineral deposited. For many details the original must be consulted. L. W. RIGGS

The influence of superimposed strata on the deposition of certain lead-zinc ores. R. A. MACKAY. *Bull. Inst. Mining Met.* 1925, No. 254, 14 pp.—The presence of certain Pb-Zn ore bodies may be explained by assuming that the impounding strata have acted as a semi-permeable membrane, permitting the H_2O of the ore-bearing solns. to pass but keeping back the minerals. The process has been that of osmosis. Evidence from ore-bodies in the Carinthian Alps is brought forward. J. F. SCHAIERER

Molybdenum, its metallurgy, uses, occurrences, mining and ore concentration. V. L. EARDLEY-WILMOT. *Can. Dept. Mines, Mines Branch No.* 592, 285 pp. (1925).—Deposits of Mo throughout the world are described, those of Canada in greater detail.

Costs, analyses and methods of concn. are treated at length, as are the uses of Mo in the various steels. L. W. RIGGS

Asbestos deposits of Arizona. JOHN MELHASE. *Eng. Mining J.-Press* 120, 805-10 (1925).—The asbestos was formed through the hydrothermal alteration of magnesian limestone induced by the intrusion of diabase sills. Confined gases and thermal solns. from the diabase acted on the first-formed serpentine to produce asbestos seams or, if unconfined, escaped without forming asbestos. J. F. SCHAIRER

Pre-Cambrian rocks of Gunnison River, Colorado. J. FRED HUNTER. U. S. Geol. Survey, *Bull.* 777, 94 pp. (1925).—This study is mainly petrographic. Chem. analyses are reported or quoted of 12 samples of the rocks. L. W. RIGGS

A carbonatite from the Lake Laach region. ADELE BRAUNS AND R. BRAUNS. *Centr. Mineral. Geol.*, A 1925, 97-101.—The rock consists of 90% calcite with small quantities of alkali feldspar, nosean, acgirine, biotite, apatite, pyrrhite and zircon. It is believed to be a magmatic differentiate belonging to the series of calcite-rich rocks (nosean-syenite, cancrinite-syenite, calcite-syenite, syenite-pegmatite) found in the region. J. E. GILL

The formation of limestones in fresh water lakes and in seas. A comparison. HANS KLAHN. *Z. deut. geol. Ges.*, B 1925, 3-24.—Lake-chalk is mostly formed from physiologically sepd. CaCO_3 . The weight of evidence indicates, though less certainly, that marine limestones are also dominantly of org. origin. J. E. GILL

Theory of coal measure fire clays. E. LOVEJOY. *J. Am. Ceram. Soc.* 8, 756-61 (1925).—It is "reasonable to assume that these beds are altered sedimentaries instead of residuals." C. H. KERR

The Cambrian sediments of the Karelisch Isthmus. B. FROSTERUS. *Bull. comm. geol. Finlande* No. 75, 5-52 (1925). Analyses of clay-slate, clays, phosphorite nodules and waters leached from clays are included. J. F. SCHAIRER

The presence of sulfate-reducing bacteria in oil field waters. E. S. BASTIN, F. E. GREER, C. A. MERRITT AND GAIL MOULTON. *Science* 63, 21-4 (1926).—No valid evidence has yet been obtained of the reduction of sulfates and the formation of sulfides by the agency of dead org. material at ordinary temps. At high temps. such reductions do take place. Reduction of sulfates in oil field waters through the agency of anaerobic bacteria does take place at ordinary temps. J. W. RIGGS

Radioactivity and the earth's thermal history. IV. A criticism of Parts I, II and III. ARTHUR HOLMES. *Geol. Mag.* 62, 504-15 (1925); cf. *C. A.* 9, 1293, 2052; 10, 2085.—The theory that the earth has continuously cooled down from a former molten state is shown to lead to limitations of temp. and to a distribution of rock-types at moderate depths which make it impossible for igneous activity to have taken place as it is known to have done. This conclusion proves the theory wrong. V. **The control of geological history by radioactivity.** *Ibid* 529-44.—Instead of deducing the distribution of rock-types in depth from their radioactive contents an attempt is made to det. the distribution independently so that the radioactive effect may be deduced without reference to any limiting hypothesis of a steadily cooling earth. J. F. S.

The composition of the earth's interior. L. H. ADAMS AND E. D. WILLIAMSON. *Smithsonian Rept. for 1923*, 241-60 (1925).—The sources of information concerning the interior of the earth are discussed:—constant of gravitation, astronomic and geodetic data, flattening of the earth and seismologic data. A. and W. conclude that the earth's core is metallic Fe or Ni-Fe. Surrounding the Fe core there is a fringe of mixed Fe and silicate, and finally a silicate shell. The earth, except for the small surface shell, consists almost entirely of Fe, Mg, Si and O. J. F. SCHAIRER

Nature of the interior of the earth. E. WIECHERT. *Nachrichten Ges. Wiss. Göttingen* 1924, 251-6.—A discussion of the possible phys. and chem. conditions in the various zones of the earth's interior. J. F. SCHAIRER

Making thin sections of rocks. MARY G. KEYES. *Am. J. Sci.* 10, 538-50 (1925).—A detailed review. L. W. RIGGS

GRUBENMANN, U. and NIGGLI, P.: **Die Gesteinsmetamorphose.** Berlin: Gebirger Borntraeger. 539 pp. Reviewed in *Econ. Geol.* 21, 99 (1926).

QUIRKE, T. T.: **Elements of Geology.** New York: Henry Holt and Co. Cloth. 6 × 9 in. 414 pp. 102 halftones, 45 line cuts \$3.50. Reviewed in *Eng. News Record* 95, 644 (1925).

VEN, R. W. VAN DER: **Minerography and Ore-deposition.** Vol. I. The Hague: G. Naeff. £1, 1s. Reviewed in *J. Chem. Met. Soc. S. Africa* 26, 117 (1925).

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, ROBERT S. WILLIAMS

Fifty-seventh annual review and year book number. *Eng. Mining J.-Press* **121**, No. 3(1926); cf. *C. A.* **19**, 809.—This number contains mining and trade information for the year 1925 on Cu, Pb, Zn, Au, Ag, Fe, petroleum, Mn, Ni, chromite, W, Co, Mo, Pt, Hg, As, Sb, Bi, bauxite, Al, Ra, U, V, Cd, Ce, Se, Te, Ti, Th, Zr, asbestos, mica, graphite, talc, tripoli, diatomite, SiO₂, feldspar, kaolin, gypsum, magnesite, barytes, fluor spar, borax, phosphate rock, nitrate, potash, S and pyrites; regional summaries of the mining industry are given; and papers on *Milling and Flotation* by C. E. LOCKE, *Hydrometallurgy* by A. W. ALLEN, *Pyrometallurgy* by E. H. ROBIN and *Iron and steel metallurgy* by BRADLEY STOUGHTON. E. H.

The non-ferrous metals industry in 1925. ANON. *Ind. Chemist* **2**, 13(1926). E. H.

Lead and zinc in eastern Canada. F. J. ALCOCK. *Mining and Metallurgy* **7**, 51-6(1926). E. H.

Platinum and allied metals in 1924. J. M. HILL. U. S. Geol. Survey, *Mineral Resources of U. S., 1924*, Part I, 45-57(preprint No. 7, published Oct. 19, 1925). E. H.

Silver, copper, lead and zinc in the Central States in 1924. J. P. DUNLAP AND F. BEGEMAN. U. S. Geol. Survey, *Mineral Resources of U. S., 1924*, Part I, 59-88(preprint No. 8, published Jan. 12, 1926). E. H.

Regenerative gas-fired furnaces. Equipment at a new French non-ferrous works. ALFRED HARVEY AND H. W. JACKSON. *Metal Ind.* (London) **28**, 9-13(1926).—A brief illus. description of a regenerative gas-fired furnace installation for the melting of Cu, brass and Zn. Advantages claimed for this type of furnace are: (1) increase of life of the crucible, (2) flexibility of temp., and (3) economy of fuel, which averages a saving of 1/3. Annealing is conducted in a muffle type of furnace, which has a movable bed on wheels, with 1/2 the bed inside the furnace holding the strips or plates being annealed, and the other outside where it is unloaded and reloaded. Time is saved by having the unloading, loading and annealing simultaneous. The existence of a critical temp. at about 400° is here shown on a commercial scale. W. H. BOYNTON

Engineering and science in the metal industry. ZAY JEFFRIES. *Mech. Eng.* **48**, 8-16(1926).—An address in which are reviewed the growth of the metal industry since 1885, the selection of an alloy or metal for a given purpose, factors governing the properties of an alloy, prevalent theories of the causes of hardness in steels and the effect of science on the metal industry. ALBERT THOMAS FELLOWS

Manufacture and use of die castings. FR. IHRMANN. *Z. Metallkunde* **17**, 329-33(1925).—A brief description of the machinery used in die casting, and of the articles made from Pb, Sn and Al alloys by means of this process. H. S. v. K.

Improving plate amalgamation. IRA LEMMON. *Eng. Mining J.-Press* **121**, 70(1926).—Blowing air on the plate, by means of a pair of parallel pipes pierced with small holes at 1-in. centers and placed across the plates so as to direct the air streams up the plate, will remedy flouing of Hg. and is better than a shaking plate. A. BUTTS

Treatment of metal residues and scrap. I. Treating white metal residue in the melting pot. (B) Production of white metal alloys, zinc and lead. II. Treatment of tin residues. E. R. THEWS. *Metal Ind.* (London) **27**, 307-10, 453-5(1925). III. The treatment of aluminium scrap. *Ibid* **28**, 29-33(1926). W. H. BOYNTON

Possible improvements in metallurgical practice relating particularly to the zinc industry. GILBERT RIGG. *Bull. Inst. Mining Met.* **1925**, No. 254, 2-26; cf. *C. A.* **20**, 163.—A discussion. The possibilities of establishing a superphosphate industry to utilize the excess H₂SO₄ from the Zn smelting industry is brought out. Cheap water power is not absolutely essential for economic success of the electrolytic process. More should be known of the phys. chemistry connected with the condensation of Zn vapor. Strong points of the electrothermic and the electrolytic processes are pointed out. W. H. BOYNTON

The metallurgy of quicksilver. I. H. DUSCHAK AND C. N. SCHUETTE. *Bur. Mines, Bull.* **222**, 167 pp.(1925).—A treatise including history, ores, roasting, concn., drying, sampling, assaying, roasting and distn. furnaces, retort furnaces, condensation, wet treatment, health hazards (by R. R. SAYERS), and bibliography. The design of leading furnaces and condenser systems is given in detail. It is concluded that in the direct furnace treatment of ores the major problem in the extn. of Hg has been solved, methods being available whereby low-grade ores can be treated with remarkably high

recovery and at low cost. The greatest opportunity for increasing economy in Hg production lies in more attention to geology of deposits and improvement of mining methods.

A. BURRS

Metallurgy of silver-lead ores at the Transvaal Silver and Base Metals, Ltd. W. G. GENTLES. *J. Chem. Met. Soc. S. Africa* 25, 265-95 (1925).—A very detailed description with flow sheets and cost data is given of the ore dressing and smelting of the concentrates obtained from the Ag-Pb mine of the above company near Pretoria. The ore vein contains galena, pyrite, chalcopyrite, blende, jamesonite and traces of Ag minerals, associated with quartz, chlorite, calcite and dolomite. The coarse ore from the mine is roughly broken, screened and the oversize hand-picked by native labor; the residue is coarsely crushed and concd. by jigging, followed by fine grinding of the jig tailings and subsequent flotation together with slimes produced earlier. The concentrates from the mill and the hand-sorted ore are pre-roasted in a Godfrey furnace until they contain 9-11% S, sintered in Huntington-Heberlein pots, and smelted in a blast-furnace to obtain argentiferous Pb for sale. The mat produced contains 10-14% Cu, and is roasted, sintered and smelted to yield a richer mat contg. 45-50% Cu, which is sold to Cu refiners.

B. C. A.

Application of pulverized coal to copper-refinery furnaces. E. W. STEELE. *Trans. Am. Inst. Min. Met. Eng.*, May, 1925 (advance copy) 10 pp.—Pulverized coal can be used in reverberatory Cu-refining furnaces with the same thermal efficiency as oil, and the upkeep of the furnace brickwork is generally less than with oil, as the flame action is not so severe. In full-scale trials the furnaces were heated by 3 burners, each 12 in. diam. and delivering 67 lb. of coal per min. at the max. rate of firing during the melting period, with a max. gas velocity of 3550 ft. per min. at the burner tip. A pressure of 2 oz. per sq. in. in the air main was sufficient, and during the charging and tapping periods 1 burner only was in use. The fuel supplied should not contain more than 8% of ash and 2% of S, and with suitable design of flues and regulation of draught it is estd. that not more than 25% of the ash remains in the furnace. During a period of 20 days 20 charges averaging 185 tons of Cu were refined with an av. coal consumption of slightly less than 200 lb. per ton of Cu, as compared with 250 lb. with good hand-firing practice.

B. C. A.

Recovery of arsenic and other valuable constituents from speiss. C. P. LANVILLE. *Trans. Am. Inst. Min. Met. Eng.*, May, 1925 (advance copy) 13 pp.—For the recovery of the constituent metals from a speiss contg. on the av. Pb 21.4, Cu 30.1, Fe 10, Ni 7.3, Co 1.8, As 18.7, Sb 4.6, S 3.4, Zn 2.1%, etc., Au 0.76 oz. and Ag 201 oz. per ton, the coarsely crushed material was melted rapidly with 20% of S on a sloping magnesite hearth of an oil-fired reverberatory. The molten product sepd. into 2 layers, a lower layer, 53% of the original speiss, consisting of enriched speiss and an upper layer (65%) of mat. The speiss assayed Pb 4.3, Cu 12, Fe 10, Ni 13, Co 3, As 35, Sb 8.6, S 7%, Ag 37 oz. and Au 1.3 oz. per ton, and the mat, Cu 36, Pb 29, Ni + Co 0.8%, Ag 335 oz. and Au 0.1 oz. per ton. The latter was returned to the blast furnace and the former crushed to pass a 20-mesh sieve, roasted to expel as much As as possible, and fused with 16% of S and sufficient coal to reduce the oxides. The new speiss (26% of original) assayed Pb 2, Cu 10, Fe 7, Ni 25.7, Co 5.9, As 34, Sb 10, S 7%, Au 2.3 oz. and Ag 36 oz. per ton; the mat (10%) contained Pb 17.6, Cu 37.3, Ni and Co 1.8%, Ag 145 oz. and Au 0.7 oz. per ton at the same time 9 1/2% of As was recovered as trioxide in the fume plant. The new speiss was finely ground and again roasted until all the S was expelled, more As being recovered from the fume. The roasted product contained about 16% As and 0.3% S; sufficient Na carbonate was added to combine with all the As and S remaining and roasting was continued in a Godfrey single-hearth furnace until all the As was converted into trisodium arsenate, which was extd. by leaching the material on the counter-current principle, a small quantity of Na₂S being added to the leach liquor after filtering to remove the small quantity of Cu that dissolved. The liquors were evapd. until they solidified on cooling to a product assaying about 56% Na₂AsO₃, 1.3% Na₂SO₄, 1.9% Na₂CO₃, 40% H₂O. The residue from leaching was about 21% of the original speiss and contained Pb 2.5, Cu 12.5, Fe 8.7, As 1.3, Sb 11.7, Ni 31.3, Co 7.4%, Au 2.9 oz. and Ag 46 oz. per ton. This mud was mixed with H₂SO₄ (d. 1.8), passed through a heated rotating drum in a thin stream and into a conical dissolving tank contg. water agitated by a current of air. The overflow from the tank passed to a settling tank. The slimes were thickened by addn. of lime to neutralize acidity and returned to the blast furnace; they contained Pb 5, Sb 25, Cu 3, Co and Ni 2.3%, Au 6 oz. and Ag 97 oz. per ton. The sulfate soln. was electrolyzed for Cu, concd. by steam coils in lead-lined vats to d. 1.45, and finally evapd. in open cast-iron pans to d. 1.65. On cooling the bulk of the metal sulfates sepd. out in the anhyd form and the

supernatant acid was returned to the dissolver. The sulfates were carefully roasted until the Fe and As were rendered insol. and the mass was leached to obtain a soln. of Ni and Co sulfates from which Co was recovered by treatment of the soln. first with limestone to sep. Fe, then with H_2S to remove Cu and Zn, and finally with $NaClO$ to ppt. the Co.

E. H.

Pouring ingots by a new method. ANON. *Iron Age* **117**, 128-9(1926).—The reservoir and multiple-pouring float method is designed to reduce pipes and blowholes in steel. The delay in descent of the metal in the reservoir has the effect of filling up more of the pipe, thereby yielding a sounder steel. In addition to the sounder castings, other advantages claimed are: a longer life from stools, buggies and ingot molds. The no. of stool stickers is reduced and broken buggy axles rarely occur. Little refractory material reaches the soaking pits and practically none is encountered beneath the roll trains, insuring cleaner scale for use in the blast furnace. Several illustrations are included.

W. H. BOYNTON

Relation of carbon consumption to material smelted in the blast furnace. S. P. KINNEY. *Blast Furnace & Steel Plant* **14**, 15, 25(1926).—Operating data are tabulated which show the relation of C consumption to the quantity smelted and the effect of high-ash coke. There is a fixed relation between the amt. of C consumed and the amt. of material smelted. According to the calens., an av. of 2.67 lbs. of material was smelted per lb. of C consumed. A check run showed 2.64 and another furnace showed 2.68

Genuine open-hearth iron. F. J. CROLIUS. *Blast Furnace & Steel Plant* **14**, 25-36, 48(1926).—An illus. description of the Andrews Steel and Newport Rolling Mills in the Cincinnati, Ohio district. The same kind of coal is used: in gas producers for the open-hearth; pulverized on sheet and pair, and annealing furnaces; and in the finer screenings for steam purposes on stokers. The pulverized-fuel layout is discussed in detail.

W. H. BOYNTON

Production and application of oxygen-enriched air in foundry practice. A. BRÜNINGHAUS. *Stahl u. Eisen* **45**, 737-48(1925).—Various methods for the production of O by liquefaction and sepn. from air are discussed and the necessary equipment for a foundry installation is described. In blast-furnace practice the advantages of using O-enriched air are greater output, elimination of blast preheater, diminution in size of blowing machines, better regulation by changing the compn. of the air. The coke consumption increases, but the temp. at the throat falls. Heat balances are given for 2 furnaces with hot blast and O-enriched air, resp.; the total heat consumption is less for the latter but there is a greater amt. of waste gas which can be used in gas engines, and lower-grade ores can be treated. In the converter process the heat loss due to the N in the blast is reduced, the time of blowing is shortened, and a greater proportion of scrap can be used. The output of 4 converters with O-enriched air was the same as that of 6 converters with ordinary blast, the quality of steel being the same. A higher temp. was obtained at the beginning of the blow and pig iron low in P could be blown. The Fe content of the slag was somewhat higher. In the Siemens-Martin process, using O-enriched air, regenerators are not necessary and the use of coal-dust firing is made possible. Greater heat is brought to the hearth and heat is also made available for steam raising. The heat consumption per ton of steel by 4 different methods of firing was investigated: coke-oven gas with atm. air gave the most favorable results. Expts. at the Hoesch Works are described using coke-oven gas with air enriched to 28% of O, the N being pumped into the compressed-air system. A special type of burner used is described. Refining proceeds rapidly in the furnace, which is advantageous in the pig iron-ore-process. Favorable results were obtained by firing with coal dust and air with a 40% O content. A diagram is given of the heat flow through the furnace.

B. C. A.

Factors affecting the elimination of sulfur in the basic open-hearth process. C. H. HERTY, JR., A. R. BELYEA, E. H. BURKART AND C. C. MILLER. *Am Inst. Min. Met. Eng.*, May, 1925 (advance copy) 21 pp.—The distribution ratio of S between the furnace gas and Fe oxides formed on melting a charge and slags containing lime, resp. and the rates of sulfurization and desulfurization of slags by gases have been detd. In an exptl. furnace of 1-4 lb. capacity illuminating gas to which pure SO_2 was added as desired was used as the heating agent and the slag was a synthetic mixt. free from S. Expts. on com. furnaces were also made. The ratio vol. % SO_2 in gas: % S in oxide was found to be about 0.9 and the ratio vol. % SO_2 in gas: % S in lime slags was 0.27. The use of a gas free from S allows a charge contg. more S to be used in the furnace

and will prevent the loss of time due to high-S heats, so being economical under certain conditions. Coke-oven gas free from S is economical under most conditions and is more so than producer gas on account of the larger vol. required of the latter. It has been calcd. that unless the time lost on high-S heats is more than 1.5% of the working time there is a direct loss in using producer gas free from S. Waste gases from an open-hearth furnace should not contain more than 0.035% of SO_2 if absorption of S is to be avoided.

B. C. A.

Smelting with small coke. A. WAGNER. *Stahl u. Eisen* 45, 929-35 (1925).—Comparative tests have been made in a small iron blast furnace to ascertain the relative merits of smelting with very large coke as practiced in Germany and with coke of medium size (20% > 4 in., 25% 3-4 in., 25% 2-3 in., and 30% finer than 2 in.) as practiced in America. Other things being equal, the finer coke produced a flue gas poorer in CO, showing better utilization of the fuel, and a higher percentage (1.3-1.6 against 0.8-1.1) of Si in the Fe, while slightly less coke was required to produce 1 ton of pig-iron. Further tests on an iron ore which contained Pb showed that iron perfectly free from Pb could be made by smelting this ore with the finer coke because of the high temp. in the combustion zone causing complete volatilization of the Pb; with coarse coke, Pb accumulated in the hearth of the furnace. When small coke is used care should be taken that it has sufficient strength and hardness not to crumble in the throat of the furnace, and preferably all lumps smaller than 20 mm. should be sieved out before use.

B. C. A.

Effect of zinc oxide on the formation temperatures of some ferrous slags. H. T. MANN. *Trans. Am. Inst. Mining Met.* 1925 (preprint) No. 1474 D, 25 pp.—Slagging of Zn in Pb blast-furnace smelting is often of great importance. Under proper conditions slags as high as 38% in ZnO have been run, but 15-18% was formerly regarded as the upper limit. Results are here tabulated and plotted of detns. of formation temps. of ferrous slags contg. from 0 to 60% ZnO, with variations in SiO_2 , FeO and CaO as in practical smelting. Weighed mixts in the desired proportions were molded into cones of the Seger type and heated to fusion in a gas muffle. Replacement of FeO by ZnO lowers the slag-formation temp. up to a certain percentage of ZnO, then increases it. The same is true in general of replacement by SiO_2 by ZnO and to a small extent of replacement of CaO. Many combinations can be smelted and produce a high-Zn slag, but careful regulation is necessary to avoid serious trouble, especially in the ratio of FeO to ZnO. Charges must be carefully proportioned and mixed to avoid a burden with a slag formation temp. higher than the furnace can attain. A. B.

Granulation of blast-furnace slag. G. HARTMANN. *Stahl u. Eisen* 45, 529-30 (1925).—In the process in use at Ilsele the slag is granulated by falling from a height into water contained in a chamber at the base of a wooden tower, which carries away the water vaporized, contg. SO_2 . The product is elevated to a storage hopper when it is discharged contg. 8-9% of moisture. The speed of the elevator and the amt. of water used are regulated by the quantity of slag. The process may be modified to deal with slag from any type of furnace.

B. C. A.

Drying blast-furnace slag on a suction drainer. A. KOERFER. *Stahl u. Eisen* 45, 530-1 (1925).—The slag, granulated in water, is elevated by an air lift and distributed evenly over the suction bed. This consists of perforated metal plates through which the water is drawn, while rotating scrapers prevent clogging of the bed and deliver the material continuously into storage hoppers. The water is used again after allowing the fine sand it carries to settle out.

B. C. A.

Drying granulated blast-furnace slag. A. LIEBRICH. *Stahl u. Eisen* 45, 531-2 (1925).—In the process in use at the Roland foundry the slag is plunged into water so that it becomes spongy in texture and is then delivered to a rapidly rotating table where it is sepd. from the water; a product of any desired compactness or water content can be obtained. The material possesses the same hydraulic properties as granulated slag prep'd. by the usual methods.

B. C. A.

Drying blast-furnace slag. F. SCHNEIDER. *Stahl u. Eisen* 45, 532-3 (1925).—In the process used by the Gelsenkirchener Bergwerks A.-G. the slag is delivered into a specially designed mill where it is disintegrated by rotating blades in a water spray the amt. of which is regulated to give a dry product. A considerable proportion of finely divided material is produced which is very suitable as a raw material for cement manuf. while the power required to grind the product is about $\frac{2}{3}$ of that required for slag granulated by a wet process.

B. C. A.

Air drying of blast-furnace slag. M. ZILGEN. *Stahl u. Eisen* 45, 533-6 (1925).—In the Buderus process, the molten slag is delivered to a tower where it is disintegrated by an air blast in conjunction with a water spray which is regulated to produce a dry

product. The material passes through a screen before reaching the storage hopper. The product is at least equal to that obtained by the wet process for use in the manuf. of cement. B. C. A.

Heats steel hotter. D. M. AVEY. *Foundry* **54**, 88-91, 124(1926).—A description of a new type of open hearth with self-contained gas producers and its operation. Temps. above 3500° F. are attained. F. H.

Tests for molding sand. A résumé of tentatively adopted methods of tests developed by the Joint Committee on Molding Sand Research of the American Foundrymen's Association. *Metal Ind.* (N. Y.) **23**, 99-102, 277-9, 493-5(1925).—Tests include: binding strength, fineness, permeability, chem. analysis, dye absorption and method of sampling. The procedure and equipment used are outlined. W. H. BOYNTON

Metal mold by a new process. M. S. CLAWSON. *Iron Age* **116**, 1310-3(1925).—Accurate castings are claimed possible by the "Plastic Process" using a new elec. resistance furnace and permanent molds. They may be made to almost exact size and form. Steel and Ni alloys require only grinding and finishing to obtain complete dies for stamping or a mold for forming materials. Another advantage is the possibility of using non-corrosive alloys. The process is not described but several illustrations of applications are mentioned. When air pocketing is once eliminated in the permanent molds no further trouble is experienced with the filling of the mold and the structure of the metal in the molds is fine-grained and possesses a more uniform surface. W. H. BOYNTON

A description of the Perlit process. H. J. YOUNG. *Iron & Steel Can.* **8**, 242-3(1925); cf. *C. A.* **19**, 2799.—A new method of producing grey iron castings under new condition is outlined. Lower Si and lower P contents are possible by this method. W. H. BOYNTON

The recrystallization of rolled plate silver. R. GLOCKER, E. KAUPP AND H. WIDMANN. *Z. Metallkunde* **17**, 353-7(1925); cf. *C. A.* **19**, 1682.—A bar of cast Ag contg. 99.7% Ag and 0.2% Cu was used. X-rays gave valuable information on the recrystn. of Ag plate and on grain growth. Up to 200° the crystallite was extraordinarily small, but at 212° a considerable change took place and a large increase in newly formed crystals was indicated. Up to 700° no further change was indicated but above that temp. changes occurred and great numbers of crystallite particles seemed to have taken the recrystn. position. At 850° the no. of particles seemed to be greatly increased and at 910° complete transformation into the regular orientation had taken place and all the particles lay in the same direction. There is a corresponding increase in grain size. Röntgenographs and photomicrographs are shown. A mixt. of NH₄OH and H₂O₂ was most suitable for etching. The results are confirmed by mech. tests, curves for Brinell hardness and elongation being shown. H. STOERTZ

A further note on bright drawn steel. R. T. ROLFE. *Iron Foundry, Metal Ind.* (London) **27**, 343-4(1925).—Examples show the defective compn. of some bright drawn steels. The assistance to "free machinability" given by S and P is insufficient to warrant excess of these elements over the min. to give the property desired. More attention should be given to the service requirements. The compns. of typical grades of bright drawn steel bars are tabulated. Much bright drawn steel of "free cutting" quality contains too much S and is liable to fracture. Special attention must be given where the steel is subject to shock. W. H. BOYNTON

Improvements in automotive steels. W. G. HILDORF. *Iron Age* **116**, 1378-80, 1447-50(1925).—Points discussed include: difficulties due to seams and dirty steel, normal and abnormal steels, the effects of heat treatment, the need for greater uniformity from heat to heat, detn. of fatigue values by fractures, variations in grain size and fracture testing. Fracture testing is important in automotive lines. Normal and abnormal steels are distinguished by metallographic examn. Abnormal steel exists in all classes and is more liable to give soft spots and warpage. No fatigue machine gives results exactly comparable with those obtained in service. Impact values and Brinell hardness are shown with various drawing temps. W. H. BOYNTON

Density measurements at high temperatures. VI. The volume changes occurring during the melting of pig iron. F. SAUERWALD AND J. WECKER. *Z. anorg. allgem. Chem.* **149**, 273-82(1925); cf. *C. A.* **18**, 3346.—Pellets of white pig Fe were made in a magnesia crucible by melting under an atm. of H the proper proportions of pure Fe, Mn and Acheson graphite. The sp. vol. at 20° was 0.1293 ($\pm 0.2\%$). The m. p. was 1155° and the solidification p. 1137°. Ac₁ and Ar₁ points were 738° and 663°, resp. The sp. vol. of the Fe before and after melting and over the temp. range 1082-1209° was detd. by measuring the weight of the pellet when immersed in molten NaCl. The previously detd. values for the d. of NaCl were used in the calcn. The sp. vol.

of grey pig Fe, samples of which were prepd. in an earlier investigation, was detd. in the same way. The evolution of gas that invariably accompanied the immersion of the untreated Fe pellets in molten NaCl was avoided by coating the pellets electrolytically with a thin Ni film. It was found that white pig Fe increased in vol. on melting, while grey pig Fe decreased. The liquids differed in sp. vol. by only 1%. The figures are for white pig Fe: before melting ν , 0.139, d. 7.15; after melting ν , 0.1418, d. 7.05; for grey pig Fe: before melting ν , 0.1449, d. 6.90; after melting ν , 0.1435, d. 6.97.

R. L. DODGE

Ferro-nickels. PESCHARD. *Rev. métal.* 22, 490-514, 581-609, 663-85 (1925); cf. C. A. 19, 2773, 2907.—After a review of previously published work, P. describes in detail his own work on the magnetism of Fe-Ni alloys contg. 0-100% Ni, which leads to the following conclusions. Alloys contg. more than 34.4% Ni are completely reversible at all temps.; those contg. less than 34.4% Ni are irreversible below a temp. which varies with the Ni content and which probably represents the beginning of the allotropic $\beta \rightleftharpoons \gamma$ transformation of Fe-Ni. The variation in magnetic properties is continuous from 100% Ni to 100% Fe, but with 3 discontinuous points, which are the angular points on the at. moments curve, the Curie const. curve and the Curie point curve. The corresponding proportions of the metals can be represented by a simple formula, suggesting the presence of definite compds. in the alloys: Fe_2Ni , Fe_3Ni_2 , FeNi_2 , of which nothing is known and 2 of which are not revealed by the other phys. properties. The at. moments of these compds. satisfy the law of whole nos. of magnetons; FeNi_2 probably contains 20 magnetons per mol. At 0° abs. and very low temps. reversible Fe-Ni forms 3 series of solid solns. contg. Ni and FeNi_2 , FeNi_2 and Fe_3Ni_2 , Fe_3Ni_2 and Fe_2Ni , resp. With irreversible alloys, the exptl. results would indicate that the stable equil. is represented by a solid soln.; but the structure of nickeliferous meteorites would indicate that with extremely slow cooling there are formed 2 phases, camacite and taenite, the segregation of which is possibly facilitated by the impurities present. The segregation accompanies a physico-chem. transformation the nature of which is uncertain but can be linked up with the compd. Fe_2Ni . P. suggests that at very low temps. the irreversible alloys contain 3 constituents, α -Fe, Fe_2Ni with 9 magnetons and Fe_3Ni_2 with 12 magnetons. This displacement of the equil. between the 2 varieties of Fe_2Ni might account for the peculiarity of the law of magnetization as a function of temp. At high temps. (900° and over) all the ferro-nickels are solid solns. when stable, the constituents of which (Fe_2Ni , Fe_3Ni_2 , FeNi_2) are apparent on the curve of Curie's const. The irreversible ferromagnetic and paramagnetic changes are not independent of one another and doubtless accompany the $\beta \rightleftharpoons \gamma$ transformation of the Fe. Bibliography of 48 references.

The metallurgical aspects of modern boiler practice. L. P. SIDNEY. *Chem. Age* (London) 14, 2-3 (1926).—The growing necessity of fuel economy is causing changes in boiler pressures and temps. and, therefore, on boiler construction. As regards static and dynamic stresses, the question of ultimate elasticity is bound up with the time factor. The question of the behavior of metals, particularly at high temps., involves conditions the exact opposite of those embodied in the classical conception of elasticity, namely, plasticity and viscous flow. The consensus of opinion is that the strength of boiler plate can be satisfactorily increased by the use of steel of high quality contg. certain ams. (as yet undetd.) of Ni and Cr.

W. H. BOYNTON

Tensile tests of crystals of an aluminium zinc alloy. C. F. ELAM. *Proc. Roy. Soc. (London)* 109A, 143-9 (1925).—By the method of straining and heat treatment large crystals were grown in an alloy of Al contg. 18.6% Zn. The crystals rarely exceeded 2 in. in length and 0.5 in. in diam., and the test pieces were smaller. The breaking load varied from 15.08 to 21.70 tons per sq. in. with elongations around 20%. The strength depends on the orientation of the crystal and the consequent type of fracture. The addition of the Zn to Al does not destroy the cubic symmetry of the crystal. The hardness is very much increased. Fracture occurs on planes nearly at 45° to the axis and may occur along the slip-plane, but not necessarily. The tensile strength of single crystals appears to be higher than that of the polycrystalline material. A. W. K.

"Koltchougolumin." V. BOUTALOV. *Messenger de l'industrie des métaux russe* Nos. 1-3, 109-28 (1924); *Rev. métal* 22 (Extraits), 426-9 (1925).—By addn. of Ni to Al alloys, B. obtained an alloy similar to duralumin, contg. small quantities of Cu, Ni, Mn and Mg, the exact compn. of which is not disclosed. It has d. 2.8, tensile strength

up to 60 kg. per sq. mm., can be rolled immediately after casting without heat treatment, and can be machined, forged, etc. On quenching from 500° (not below 490°) it is hardened, but the improvement does not occur immediately, but only after about 8 days. Hardening can be accelerated by immersing in boiling water after quenching. Quenching increases both the tensile strength and elongation. Repeated quenching does not further affect its mech. properties. Fusion is carried out in a crucible furnace, overheating being avoided. Slag is eliminated by addn. of 0.1% ZnCl_2 , either solid or fused, stirring and removing the scum. Mn and Cu (in the form of Al alloys) and Ni (as German silver) are placed in the crucible together with the Al, and the Mg is added just before pouring. The m. p. of the alloy is 650° and it is poured at 750°. B. succeeded in keeping the compn. of the alloy const. after repeated fusions, even avoiding loss of Mg. The mech. treatment of the alloys (rolling, drawing, manuf. of pipes) is described and the official Russian specifications are given. A. P.-C

Boron in aluminium and aluminium alloys. PAUL HAENNI. *Compt. rend.* **181**, 864-6(1925).—Results of tensile and hardness tests are tabulated for: 7 Al-B alloys contg. 0-4% B; 12 Al-Cu-B alloys contg. 4.8 and 12% Cu and 0-8% B; 20 Al-Si-B alloys contg. 2.5, 5, 7.5 and 13% Si and 0-1.6% B; 6 Al-Zn-B alloys contg. 5, 10 and 20% Zn and 0-1.4% B; and 4 complex alloys. On the whole B improves the tensile strength and hardness and decreases the elongation. The addn. of B to Al-Si alloys of the nature of "Alpax" seems to produce a refining similar to Na and alkali fluorides. A. P.-C

The effect of artificial aging on age-hardened aluminium alloys. K. L. MEISSNER. *Metal Ind.* (London) **27**, 333-8(1925); cf. *C. A.* **19**, 3469. M. replies to Gayler (*C. A.* **19**, 3470). Additional proof as to the existence of MgZn_2 and to its age-hardening properties is given.

Influence of aging temperature upon the physical and chemical properties of Lantal. K. L. MEISSNER. *Z. Metallkunde* **17**, 369-73(1925).—Lantal is an Al alloy contg. 4% Cu and 2% Si, but no Mg, in contrast to the *Duralumin* group. The chief difference is that Lantal, after being heated to 500° and quenched, does not acquire desirable properties until it has been aged at elevated temp. The authors det. the effect of aging at various temps. for 16 or 24 hrs. upon Brinell hardness, elastic limit, strength, elongation, bending, etc. With 16 hr. aging, max. hardness is obtained at 150°, Brinell No. 115; max. elastic limit at 165°, 23.8 kg./mm. sq.; max. strength at 160°, 38.0 kg./sq. mm.; max. elongation at 100°, 21%. With 24 hr. aging max. elastic limit is obtained at 165°, 24.7 kg./sq. mm.; max. strength at 140°, 38 kg./sq. mm.; max. elongation at 125°. Curves are shown. In alloys which contain Mg, such as Duralumin, hardness and strength increase at the expense of workability. With this alloy *plasticity* is reduced on aging. Chem. resistance decreases with increase in temp. Thus with NaCl, samples aged 16 hrs. show a loss in wt. of about 11 g./sq. m. at 100° and 69 g./sq. m. at 150°, while when aged 24 hrs. the sharp rise in the curve takes place between 50° and 100°. Photographs are shown. H. STOERTZ

Temperature limits for the deformability of bronze with 20% tin. O. BAUER AND O. VOLLENBRUCK. *Naturwissenschaften* **13**, 1030-1(1925).—It was found from welding expts. at different temps. of Cu-Sn alloys with 20% Sn that between 587° and 798° in the region of ($\alpha + \beta$) crystals they are easily malleable; between 520° and 587° (γ crystals) less easily and not malleable at all below or above these limits. This explains the manuf. of the antique Chinese gongs. B. J. C. VAN DER HOEVEN

The hardness of the ternary alloys of lead, bismuth and cadmium. CLARA DI CAPUA. *Gazz. chim. ital.* **55**, 582-94(1925).—In the system of Pb-Cd (*C. A.* **18**, 3591) Cd enters in solid soln. in Pb and increases the hardness of the Pb considerably but for 2-100% Cd the hardness is a linear function of the compn. In Cd-Bi (*C. A.* **18**, 3034) the unannealed alloys show a max. in the hardness at the eutectic (40% Cd) which disappears on annealing. The same is true of Bi-Pb but the max. lies at 34% Bi. The hardness of ternary alloys Pb-Bi-Cd was studied in 9 sections on the ternary diagram. The results are given in detail in tables and diagrams. The more characteristic result obtained was the low hardness shown by the ternary eutectic in the alloy obtained by casting; at the binary eutectics the cast alloys showed a max. in hardness. The same characteristic is shown in Bi-Sn-Cd and in Pb-Bi-Sn alloys. Cf. the following abstr. E. J. WITZEMANN

The hardness of the ternary alloys of lead, bismuth and tin. CLARA DI CAPUA. *Gazz. chim. ital.* **55**, 594-604(1925).—The binary systems of which this is composed have been studied (*C. A.* **18**, 2320, 3034, 3594) and show different hardness curves depending on whether the alloys were cast or annealed for a long time. Seven sections of the ternary diagram were studied in detail. The results show again (cf. preceding abstr.) that the binary and ternary eutectics can give rise to anomalies in the diagram repre-

senting the changes in hardness in terms of the compn. of the alloy. The anomalies in the 1st case are often in the sense of a greater hardness and in the 2nd of a lesser hardness than that expected. Annealing always eliminates this anomaly. Annealing increases the concn. of the satd. solid solns. of Pb and Bi in Sn. E. J. WITZEMANN

The temperature determination of non-ferrous alloys. R. L. BINNEY. *Metal Ind.* (N. Y.) **23**, 405-7 (1925).—The application of the following types of temp. detn. as applied to non-ferrous alloys is discussed. optical pyrometers, radiation pyrometers, temp. cones, base-metal pyrometers (a) in protecting tubes and (b) for direct immersion, and protected rare metal couples. The potentiometer type is compared to the high and low resistance meters. A combination of the 2 methods is applied. To gage the furnace temp. Pt couples are imbedded in the bottom and connected to a central potentiometer station and an unprotected base metal couple is attached to a portable meter to det. the casting temp. A brief discussion follows. W. H. BOYNTON

Tungsten elgrain wire and a theory of recrystallization. SHIGETAKE OHASHI. *Nagoya Univ. Vol. 1925*, 117-22, *Japan J. Physics* **4**, 23A. When a metal solidifies or recrystallizes the atoms between the boundaries of 2 grains would be arranged chiefly according to the joint action of these 2 and the arrangement would probably be different from that of either grain, being more regular near either boundary. There is no discontinuity in regularity and no sharp boundary surface can be drawn between the regular and the irregular arrangements. Factors which affect the recrystn. temp. are explained and it is shown for W that an approx. relation of recrystn. temp. to the duration of heating may be given by $T = 1250 - 250 \log H$, where T is the abs. temp. and H the duration of heating in hrs. When a metal has just recrystd. the joint action of all the regularly arranged atoms in a grain would influence irregularly arranged ones at the boundary to rearrange to the same orientation as the former. This effect would perhaps be greater as the grain is greater. These rearranged atoms would in turn disturb the equil. of atoms situated near the boundary in the neighboring small grains and force them into an irregular arrangement. Thus the boundary will migrate to the interior of the smaller grain further and further until the latter disappears. As a result of such a process going on everywhere in the interior of metals, the av. size of a grain will increase with time. The recrystn. started from a nucleus is probably hindered by those which have started from the other nuclei, the metal thus being divided into many crystals with different orientations. If one could eliminate all nuclei but 1, or if one could suppress the power of starting rearrangement from all nuclei except 1, the whole mass of the metal would become 1 single grain. In view of the above idea an app. is described which is devised to transform an ordinary drawn W wire to a wire composed of 1 or more exceedingly elongated grains. The wire is heated by passing an elec. current through it between 2 terminals filled with Hg. The heated zone is displaced by traversing wire with a uniform speed less than that of the growth of a grain. The treatment is called "elgraining." Several phys. properties of "elgrain wire" are mentioned. C. J. WEST

Tensile strength of tungsten wires at high temperatures. RYOZO TAJIME. *Nagoya Univ. Vol. 1925*, 413-6; *Japan J. Physics* **4**, 23A.—Tensile strength of drawn W wires, contg. about 1% of thoria, was measured for various temps. The wire (0.076 mm. in diam. and 25 cm. long) was heated *in vacuo* by passing a direct elec. current through it; with a given load, the temp. at which the specimen should be kept in order that rupture would result in a specified time interval was detd. The results of expts. in which the time for rupture was 10 min., are shown by a curve. The tensile strengths in kg./sq. mm. at the following abs. temps. are: 300°, 310; 800°, 200; 1600°, 70; 2000°, 20; 2400°, 9; 2800°, 4.5; 3150°, 1.5. A few expts. were made to det. the effect of size and of heat treatment on the specimen before test. C. J. WEST

Rustless steel V2A and its use in apparatus construction. B. STRAUSS. *Apparaturbau* **37**, 309-11, 321 4 (1925).—See C. A. **19**, 3239. J. H. MOORE

The nature of the protective film of iron. T. FUJIHARA. *Trans. Am. Electrochem. Soc.* **49** (preprint) (1926); cf. C. A. **18**, 1970, 2677.—When a drop of distd. water is placed on a polished Fe surface an uncorroded rim appears at the edge of the drop. F. finds that the liquid on this uncorroded portion has an alk. reaction due to the presence of sol. $\text{Fe}(\text{OH})_2$. The presence of CO_2 destroys this protective film by neutralizing the alk. liquid. This permits corrosion to continue. C. J. BROCKMAN

The rustproofing of materials. M. E. McDONNELL. *Mech. Eng.* **47**, 875-80 (1925).—Data from tests in 1913 by the Penn. R. R. show steels which contain 0.25% Cu to be twice as resistant in the atm. as non-copper-bearing steel. Freight car sides of Cu steel are expected to last 15 years. The present life is 10 years. Cost and operating data for the cars are given. Paint on steel coaches is baked on in steam sheds at

120° and lasts 3 years as against 1.5 years for air-dried finishes. Details of painting are given.

Coating sheet iron with lead. ANON. *Apparaturbau* 37, 327-8(1925).—Pickel in a H_2SO_4 bath, wash free from acid, immerse in a SbCl_3 soln. until the surface turns deep black, wash, treat with ZnCl_2 , dip in molten Pb and cool in oil. The coating is so firmly attached that bending and hammering will not detach it. Cf. C. A. 16, 1068, 2104, 3627; 18, 524, 2679.

J. H. MOORE

Methods for testing the thickness of zinc coatings. HEINZ BABLIK. *Metal Ind.* (London) 28, 33-5(1926); cf. C. A. 19, 2629.—Exptl. results show the increase in wt. after Zn-coating is no measure of the amt. of coating. The various methods of finding the thickness are examd.; B. concludes that the reagents proposed by Bauer (cond. H_2SO_4 20 g., 500 cc. water and 2 g. As_2O_3) and by Aupperle (cond. HCl 100 cc. and 5 cc. of a soln. prep'd. by dissolving 20 g. Sb_2O_3 in 1000 cc. cond. HCl) are the best. Defects of gas-evolution and temp.-increase methods are pointed out.

Sodium silicate as a corrosion preventive. R. P. RUSSELL. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 47-51, *Am. Dyestuff Rept.* 15, 61-5.

L. W. RIGGS

A new burner for lead soldering. L. QUACK. *Chem. App.* 13, 17(1926); 1 cut.—The "Assa" burner.

J. H. MOORE

The properties and testing of magnetic materials. Effect of heat treatment. T. SPOONER. *Elec. J.* 22, 610(1925).—By annealing rolled elec. sheet the hysteresis loss may be reduced to 1% that of the unannealed sheet and its permeability increased many fold. Oxidation, which tends to reduce induction permeability, may be lessened by covering the sheets and by the use of a reducing atm. After punching, a second anneal is common practice where further reduction of hysteresis losses and increase of permeability is desired, as for transformers and rotating machines. In discussing "aging," it is indicated that this is entirely a temp. effect and is the % increase in Fe losses for 60 cycles and a max. induction of 10 kilogausses after the material has been subjected to a temp. of 100° for 600 hrs. A good 4% Si steel "ages" slightly. S. discusses C and alloy steels with the aid of diagrams and the changes in structure that occur at various temps. He shows that Si has a tendency to increase the A_s point, and that at 2% Si this point disappears. Reference is made to the work of Sauvour, Honda and others, on structural changes. By introducing alloying elements, such as Cr, Mn, Ni, etc., the transformation rate of Fe-C alloys is altered. Induction and hysteresis data for C steels quenched in water and in oil are included, and the effect of drawing on some of the properties of such 1% C steels is explained. Cf. C. A. 19, 2799.

A. D. S

Rust-preventive materials (SWOBODA) 26. Molybdenum, its metallurgy, uses, etc. (EARDLEY-WILMOT) 8.

GEIGER, KARL, BAUER, O. and BECK, L.: *Handbuch der Eisen- und Stahlgiesserei*. Edited by C. Geiger. 2nd ed. revised. Berlin: J. Springer.

Treating sulfide ores. R. D. PIKE. U. S. 1,570,777, Jan. 26. Sulfides in ores or concentrates of Cu, Zn and Fe or of other metals are decomposed by a soln. contg. FeCl_3 or $\text{Fe}_2(\text{SO}_4)_4$ at a temp. at or above the m. p. of S.

Extracting metals from ores. L. V. BROWN. U. S. 1,571,502, Feb. 2. A finely divided ore such as one contg. Pb, Zn, Cu or Ag is treated with moisture and with HCl gas to form sol. chlorides and the mass is dried and heated to convert base substances such as Fe and As into compds. insol. in non-acid solns. and to volatilize any uncombined As. The remaining sol. chlorides are leached out with a non-acid leaching liquor such as a soln. of NaCl, CaCl_2 or MgCl_2 and the resulting soln. is treated for recovery of its contained metals and for the recovery of the Cl as Fe chloride.

Leaching ores. W. G. PERKINS. U. S. 1,570,858, Jan. 26. In leaching Cu or Zn ores or similar materials with ammoniacal solns., the material, after leaching, is treated with a mixt. of steam and NH_3 (with or without CO_2) to prevent repptn. of Cu.

Ore reduction and cement manufacture. A. FERGUSON. Brit. 235,606, Dec. 19, 1923. See U. S. 1,567,934 (C. A. 20, 574).

Tin, molybdenum, bismuth, etc. from ores. GUGGENHEIM BROS. Brit. 235,157, June 7, 1924. Metals such as Sn, Mo and Bi, which form volatile compds. with S, are recovered from ores by heating them with a gas contg. S; e. g., S vapor, H_2S or CS_2 may be passed over Sn ore at a temp. of 800-900°. The gas is dild. with H_2O vapor, N , CO_2 , CO or mixed combustion gases to prevent reduction of Fe compds. and sweep the volatile Sn sulfide through the app. Sn may be obtained from the sulfide by electrolysis or by reduction with H, CO or the like.

Extracting copper and other metals. J. C. HOAL and METALS PRODUCTION, LTD. Brit. 235,641, March 19, 1924. Wet metal-bearing material such as the ppt. of oxidized Cu compds. described in Brit. 185,242 (C. A. 17, 53) is mixed with wood tar, coal tar or the like to effect agglomeration and facilitate sepn. from H_2O . The product may be smelted to obtain Cu contg. some Cu_2O , which can be further purified by poling.

Rotating receptacle for precipitating copper from solutions by use of iron, etc. A. RAMEN. Brit. 235,902, June 20, 1924.

Extruding magnesium. R. L. TEMPLIN. U. S. 1,570,868, Jan. 26. Mg is subjected to die-expression at a temp. of $340-425^\circ$ to form rods, wire, etc.

Blast furnace. C. H. F. BAGLEY. Brit. 235,316, March 14, 1924. In order to maintain the temp. of the hot blast, heat-insulating material is used as a lining for the H_2O -cooled tuyère, removable blow-pipe and connecting elbow.

Cupola furnace. F. VANDERSTEIN. Brit. 234,967, May 1, 1924.

Regenerative open-hearth furnace. N. F. EGLER. U. S. 1,570,954, Jan. 26.

Regenerative open-hearth steel furnace. B. TALBOT. Brit. 235,346, April 24, 1924.

Superposed hearth furnace for reducing iron ore, etc. J. G. AARTS. Brit. 234,951, April 10, 1924.

Slag pocket for open-hearth furnaces. F. ORTH. U. S. 1,570,704, Jan. 26.

Coal-dust and air supply for Siemens-Martin and similar furnaces. R. KRAUSS. U. S. 1,571,418, Feb. 2.

Furnace for heat-treatment of wire. A. F. JACQUEMIN. U. S. 1,571,839, Feb. 2.

Iron and steel manufacture. INTERNATIONAL METAL PRODUCTS CO. Brit. 236,273, April 1, 1924. Ingot Fe in which the aggregate of C, Si, Mn, S and P does not exceed 0.14% is produced by charging an open-hearth furnace with a mixt. of pig Fe and heavy scrap Fe contg. 35-45% of the pig Fe, together with $CaCO_3$ or other flux, melting down the charge at a relatively high temp. and adding Fe ore after the charge has sufficiently heated that this will not produce solidification, continuing the heating and finally tapping off the metal and treating it with Al or other deoxidizer (as described in the following pat.). After this treatment in a ladle the metal is run into ingot molds at a temp. of about 1600° to prevent the formation of skull in the ladle. Brit. 236,274 specifies the use of Al for deoxidizing metal in a ladle after production by a process of this character and gives details of ingot molds, etc.

Iron and other metals. L. P. BASSET. Brit. 234,853, June 2, 1924. In the manuf. of metals such as Fe or its alloys in a rotary furnace, ore is mixed with coal and fluxes, fed into the furnace and heated by injection of fuel in subdivided state with air. The fineness of the fuel and the proportion of air supplied are so regulated that 2 zones of combustion are produced in the furnace, a first or fusing zone where the coal burns to CO_2 and a second or reducing zone where the CO_2 from the first zone is converted into CO by excess fuel not burned in the first zone. The coal used may be very finely powd.

Cleaning steel sheets, etc. MADSENELL CORPORATION. Brit. 236,241, June 27, 1924. In order to remove surface C or occluded H or other gases from steel sheets or the like they are first treated with hot NaOH to remove grease, then rinsed in H_2O , pickled with dil. HCl or H_2SO_4 , again rinsed (if an acid other than H_2SO_4 is used for pickling) and treated as anode in a bath of H_2SO_4 of preferably over 84.5% strength with a cathode of Pb, Fe or steel. Brit. 236,242 specifies following up this electrolytic treatment by a treatment with Na_2CO_3 or other alk. solu. which is allowed to dry on the article and then removed with H_2O which may be slightly acidulated. It is stated that the alk. treatment causes black or dark blue substances to ooze from the metal which are removed by subsequent rinsing.

Heat-treating drill steels. G. H. GILMAN. U. S. 1,571,329, Feb. 2. The bit end of a drill steel is heated while the adjacent metal is kept relatively cool by a draft of air or other cooling fluid directed along the steel toward the heated end. The cutting end of the drill is then hardened by immersing it only in a cooling liquid and the remaining heated portion is finally quenched by gradually immersing it in the cooling liquid.

Preventing steel or other metals from adhering to molds during casting. F. VON BICHOWSKY. U. S. 1,570,802, Jan. 26. Nitrides such as those of Ti, Al or Si are used for coating molds.

Quenching bath. W. J. MERTEN. U. S. 1,571,290, Feb. 2. A bath for quenching steel after heat treatment is formed of H_2O , alkali metal chloride and cyanide and an alk. earth metal oxide, e. g., H_2O 48, NaCl 24, lime 16 and NaCN 12%.

Penetrator for testing the penetration hardness of steels or other materials. C. H. WILSON. U. S. 1,571,310, Feb. 2.

Apparatus for compacting iron, steel or similar metals. C. SCHANANDOAH. U. S. 1,571,737, Feb. 2.

Steel and iron alloys. T. G. SRIG and J. F. L. SRIG. U. S. 1,571,382, Feb. 2. An alloy is bessemerized to reduce the C content to the required degree (but not lower than that required to retain a sufficient quantity of Si to avoid the formation of nitrides), the product is pulverized and is mixed with metal oxides to oxidize the remaining Si and the mixt. is alloyed with melted Fe or steel.

Steel alloys. GLOCKENSTAHLWERKE AKT.-GES. VORM. R. LINDENBERG. Brit. 235,401, June 30, 1924. Steel alloys contain Cr 8-25, C 0.1-1.2, and Mo 0.2-4%, with or without Ni 0.5-2 or Co 0.5-2% (or Ni and Co together up to 3%). Small quantities of Si and Mn and up to 1% of V or Ti also may be present.

Aluminium-silicon alloy castings. D. B. HOBBS. U. S. 1,570,893, Jan. 26. A non-chilling mold is filled with molten Al-Si alloy, the casting is removed from the mold promptly after initial solidification, and is then rapidly chilled.

Coating with silicon. L. D. HOOPER. Brit. 234,969, May 3, 1924. Si or its alloys or silicides, either in finely divided solid form or in heated plastic or molten form, is used for spray coating various materials either directly or after a previous coating of Pb, Sn, Cu or Al is applied. Air or N or CO may be used for supplying the Si material and fluxes such as alk. metals or their halides, aluminates, borates, oxides or hydroxides or Al or Zn halides may be employed.

Coating other metals with chromium and aluminium alloys. P. F. SUMMERS. Brit. 236,033, June 17, 1924. Articles of Fe, steel or non-ferrous metals are heated (preferably in a rotating receptacle) with a mixt. of finely divided Cr-Al alloy, oxide of Cr and Al and small quantities of NH_4Cl or NaCl (if these are desired to accelerate the action), at temps. of 950° or higher, to produce a coating of a ternary alloy of Al, Cr and the metal under treatment.

Plated metal articles. V. D. DAVIGNON. U. S. 1,571,540, Feb. 2. A relatively thick and soft base metal such as brass or Ni silver is coated with a layer of Fe-Ni-Cr alloy or similar metal which is relatively hard, tenacious and resistant to HNO_3 and with an overlying surface layer of Au or other precious metal. U. S. 1,571,541 specifies a similarly coated metal article in which steel is used for the intermediate layer.

Casehardening. W. C. BASSETT. U. S. 1,571,084, Jan. 26. A casehardening compn. is formed from sawdust 12, charcoal 8 and NaHCO_3 1 part. The presence of either free or combined S is avoided.

Casehardening. W. J. MERTEN. U. S. 1,571,289, Feb. 2. A cyanide such as NaCN is heated to produce cyanogen gases and these are allowed to come into contact with the article to be treated. The cyanide is agitated by bubbling unabsorbed gases through it.

Tungsten rods, etc. NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 235,213, June 6, 1924. In making rods, blocks and the like from W or similar metals, the metal powder is pressed under such a pressure that during the sintering process crystals are formed which have dimensions of more than 1 cm.

Testing fatigue of materials. INTERNATIONAL GENERAL ELECTRIC CO., INC. Brit. 235,225, June 7, 1924. Alternating stresses are produced in the specimen by an electromagnet excited by an a. c. the source of which is the anode current of 1 or more thermionic valves.

Metal for permanent magnets. J. F. GEE AND F. S. GEE. Brit. 235,947, March 25, 1924. Before magnetizing, castings for magnets are first softened and then hardened by successive heatings and coolings. Steel contg. Co is heated to 650° for $\frac{1}{2}$ hr., cooled, heated to 1200° , cooled and allowed to stand for 18 hrs., reheated to 750° and cooled and finally heated to 1000° for 10 min., cooled and allowed to stand for 12 hrs. before magnetizing.

Coating permanent metal molds. F. MAYER. U. S. 1,570,969, Jan. 26. A colloidal soln. of graphite or the like is used for coating molds for casting Al.

Foundry molds. C. E. LEHR. U. S. 1,571,014, Jan. 26. Molds for casting steel or like metals are formed of comminuted slag 4, foundry sand 1 part and fireclay in small quantity.

Soldering flux. T. GUTTERIDGE. Brit. 235,503, Feb. 27, 1925. Anhyd. ZnCl_2 2, NH_4Cl 16, NaF $2\frac{1}{2}$ and laundry blue 2 parts are ground and mixed.

CHAS. A. ROUILLER AND CLARENCE J. WEST

X-ray analysis of organic compounds. G. SHEARER. *Science Progress* 20, 450-60 (1926).—A concise summary of the results obtained by the application of X-ray analysis in org. chemistry.

JOSEPH S. HEPBURN

The action of anhydrous aluminium chloride on nonane and on cyclopentane. MILDRED V. COX. *Bull. soc. chim.* 37, 1549-53 (1925).—Nonane when heated for 8 hrs. at 110-120° with AlCl_3 gives butane. The pentene left as a residue seems to polymerize partially into cyclopentane. This idea is supported by the fact that the latter substance is not affected by heating with AlCl_3 .

REYNOLD C. FUSON

Halogen-containing allyl halides. JULIUS V. BRAUN AND MARTIN KUHN. *Ber.* 58B, 2168-73 (1925).—From dibromohydrin (I) treated with 1.5 mols. POBr_3 , first in the cold, then on the H_2O bath and finally in boiling H_2O until the evolution of HBr ceases and then distd. under atm. pressure are obtained tribromohydrin (40% of the I) and 35-40% $\text{CHBr:CHCH}_2\text{Br}$ (II), b. 156°, d_4^{19} 2.061; with POCl_3 instead of POBr_3 is likewise obtained 40% of a nearly pure II, b. 155-6°, d_4^{19} 2.039, contg. only about 1-2% Cl instead of Br; the higher boiling fraction (210°) in this case is richer in Cl and in part doubtless consists of $\text{CHCl}(\text{CH}_2\text{Br})_2$. The addn. products of II with tertiary bases have little tendency to cryst. and are hygroscopic but the NMe_3 compd., $\text{C}_6\text{H}_{13}\text{NBr}_2$, although hygroscopic, crystals well, softens 140° and m., not sharply, 190°; the corresponding hygroscopic quaternary chloride yields an ochre-yellow chloroplatinate decomg. around 250°. The equally hygroscopic γ -chloroalkyl chloride-trimethylamine compd., m. 130-75°. These quaternary salts, which theoretically should exist in stereoisomeric forms, cannot be sepd. into products of sharp m. p. by fractionation from $\text{Et}_2\text{O-EtOH}$. The best ratio of the components for the reaction between $\text{CH}_2\text{:CHBr-CH}_2\text{Br}$ (III), Mg and PhBr (Lespicau, *C. A.* 15, 3074) is 1.1:4.1:1.5, giving 40% β -bromoallylbenzene (IV), b_{14} 94-5°; with $p\text{-MeOC}_6\text{H}_4\text{Br}$ is obtained in somewhat smaller yield 1-methoxy-4- β -bromoallylbenzene, b_{14} 140-5°. II reacts with PhMgBr like III but the isolation of the γ -bromoallylbenzene (V), b_{13} 106°, which boils nearer Ph_2 , is accompanied with greater loss. γ -Chloroallylbenzene, from $\text{ClCH:CHCH}_2\text{Cl}$, b_{13} about 76°. 1-[β -Bromoallyl]naphthalene, from III and 1- $\text{C}_{10}\text{H}_7\text{MgBr}$, b_{12} 165-70°. V with Mg in Et_2O and then with CO_2 yields a substance, m. 45-50°, which is undoubtedly a mixt. of *cis*- and *trans*- $\text{PhCH}_2\text{CH:CHCO}_2\text{H}$. Similarly, IV yields an isomeric acid, $\text{PhCH}_2\text{C}(\text{CH}_2\text{CO}_2\text{H})_2$, m. 73°. $\text{CHBr:CHBrCH}_2\text{Br}$ (VI), b_{10} 90°, in alc. with NMe_3 in Et_2O forms the addn. product, $\text{C}_6\text{H}_{12}\text{NBr}_3$, m. 150-80°, sepd. by means of alc. and Et_2O into a half m. 215° and another m. 165-70° (a mixt. of the 2 softens about 150° and m. 180°). Similarly with $\text{C}_6\text{H}_5\text{N}$ is obtained a product $\text{C}_6\text{H}_5\text{NBr}_3$, m. 140-60°, sepd. into 2 parts, m. 203° and 106-7°, resp. If either of the above 4 quaternary bromides is heated *in vacuo*, it decomps. (together with considerable decompn. in another sense) into the base and VI; the latter with NMe_3 gives again the same mixt. of quaternary salts, so that in the distn. an isomerization of VI resulting in an equl. undoubtedly occurs.

C. A. R.

The chemical manufacture of alcohol. ED. GIROD. *Rev. chim. ind.* 34, 206-9, 238-43, 273-5, 306-8, 341-4, 373-6 (1925).—A review of the manuf. of EtOH from cellulose, C_2H_2 , C_2H_4 , and of a few methods which have been proposed but have not yet been applied commercially.

A. PAPINEAU-COUTURE

Does bismuth cacodyl exist? D. GANASSINI AND U. SANTI. *Boll. chim. farm.* 64, 289-93 (1925).—By heating 2 mols. NaOAc with 1.35 mols. Bi_2O_3 a noncombustible, fuming gas with a slight garlic odor is formed. When heated alone or with H or H_2S it gives the Bi rings. It is possibly the Bi analog of cacodyl, or of cacodyl oxide. Its identity with any of the known Me derivs. of BiH_3 is excluded by its properties and mode of prepn. Kobell's test for Bi is improved by substituting $\text{C}_2\text{H}_5\text{O}_4$ for S.

Reduction of aliphatic and aromatic aldazines and ketazines by aluminium amalgam. H. MAZOUREVICH. *Bull. soc. chim.* 37, 1155-67 (1925).—Reduction of aldazines from EtCHO and Me_2CHCHO gave more secondary than primary amine. (RR':N)₂ ($\text{RR}' = \text{Me}_2, \text{Et}_2, \text{MePr}, \text{Pr}_2, \text{EtPh}$) gave chiefly RR'NH . Formation of hydrazines was slight or doubtful. Dipropyl ketazine, yellow, oil, b_{102} 177-81°. PhEt ketazone,

yellow-orange, m. 66–7°. Oxalates ($\text{H}_2\text{C}_2\text{O}_4 = \text{A}$): (Me_2CHCH_2)₂ NIH_2A , m. 245–8°; $\text{Et}_2\text{CHNH}_2\text{A} \cdot \frac{1}{2}\text{H}_2\text{O}$, softens 102–4°, m. 122–4°, $2\text{Et}_2\text{CHNH}_2\text{A}$, m. 218–20°; $2\text{PhCH}_2\text{NH}_2\text{A}$, m. 202°, $2\text{PhEtCHNH}_2\text{A}$, m. 193–5°. $\text{PhNHCON}(\text{CH}_2\text{CHMe}_2)_2$, m. 104–6°; (PhEtCHNH_2)₂ PivCl , m. 202° (decompn.). B. H. NICOLÉ

Bromosulfoacetic acid. H. J. BACKER. *Rec. trav. chim.* **44**, 1056–63 (1925).—Two methods are available for the synthesis of $\text{HO}_3\text{SCHBrCO}_2\text{H}$ (I): (1) $\text{CH}_2\text{BrCO}_2\text{H} + \text{SO}_3 \longrightarrow \text{HO}_3\text{SCHBrCO}_2\text{H}$, (2) $\text{HO}_3\text{SCH}_2\text{CO}_2\text{H} + 2\text{Br} \longrightarrow \text{HO}_3\text{SCHBrCO}_2\text{H} + \text{HBr}$. SO_3 was added drop by drop to $\text{CH}_2\text{BrCO}_2\text{H}$ and gave $\text{CH}_2\text{BrCOOS}_3\text{H}$. This when heated gave I, with the liberation of much heat (in 70% yield as the Ba salt). A small quantity of $\text{CHBr}(\text{SO}_3\text{H})_2$ was obtained as a by-product by the action of SO_3 on I, as was shown by special expts. Reaction (2) was 1st carried out in the presence of P_2O_5 but better results (76% yield) were obtained by brominating in the presence of $\text{H}_2\text{O} + \text{HBr}$, using I as catalyst, at 80° in a sealed tube. At 120° or even 100° decompn. with CO_2 formation occurs. The Na salt may also be brominated in H_2O . Free I was obtained as crystals, m. 119–5°, the Na, NH₄, Ag, Tl and Ba salts are described. It was desired to obtain $\text{CH}_2\text{BrSO}_3\text{H}$ by decompn. of I but when heated at its m. p. it decomps. by a kind of a Cannizzaro reaction thus: $2\text{HO}_3\text{SCHBrCO}_2\text{H} \longrightarrow \text{HO}_3\text{SCH}_2\text{CO}_2\text{H} + \text{HO}_3\text{SCBr}_2\text{CO}_2\text{H}$ and $\text{HO}_3\text{SCHBr}_2\text{CO}_2\text{H} \longrightarrow \text{CHBr}_2\text{SO}_3\text{H} + \text{CO}_2$. Both $\text{HO}_3\text{SCH}_2\text{CO}_2\text{H}$ and $\text{CHBr}_2\text{SO}_3\text{H}$ were isolated as the Ba salts. Andreasch (*Monatsh.* **7**, 167 (1886)) obtained the latter thus: $2\text{CH}_2(\text{SO}_3)(\text{CO}_2)\text{Ba} + 8\text{Br} \longrightarrow (\text{CHBr}_2\text{SO}_3)_2\text{Ba} + \text{BaBr}_2 + 2\text{HBr} + 2\text{CO}_2$. The aq. solns. of I may be boiled without decompn. but in the sealed tube at 200° it decomps. thus: $\text{HO}_3\text{SCHBrCO}_2\text{H} \longrightarrow \text{CH}_2\text{BrSO}_3\text{H} + \text{CO}_2$. The bromomethanesulfonyl acid was isolated as the Ba salt. With bases I is less stable than $\text{HO}_3\text{SCHClCO}_2\text{H}$. K. K.

A new reaction between triacetin and phenol and an improved method for the preparation of triacetin. SHIN ITI KAWAI. *Bull. Inst. Phys. Chem. Res.* **5**, 43–6 (1926).—After heating a mixt. of PhONa , prepd. from 28.2 g. of PhOH and 6.9 g. of Na, and 21.8 g. triacetin at 110–50° for 2 hrs., the cooled product is extd. with Et_2O (C_6H_6 is better) and distd. at 178–97° under 13 mm. It is then treated with a large amt. of H_2O : from the oily layer 2.9 g. of $\text{HOCH}(\text{CH}_2\text{OPh})_2$ is isolated as plates, m. 81–2°. Triacetin is obtained in 81% yield by shaking 70 g. of dehydrated glycerol and 525 g. of Ac_2O until a homogeneous mixt. is obtained. When the elevation in temp. of the mixt. has ceased, it is refluxed for 2 hrs. and subjected to distn. Further distn. is sufficient for purification; it b₇₆₀ 258–9°. K. K.

Compounds of formaldehyde with glycine. HUGO KRAUSE. *Z. physiol. Chem.* **150**, 306–8 (1925).—A discussion of the constitution of the glycine- CH_2O compd.; cf. Bergmann and Ensslin, *C. A.* **19**, 2809.

Absorption spectra of pyruvic acid; existence of tautomeric forms. VICTOR HENRI AND CLAUDE FROMAGEOT. *Bull. soc. chim.* **37**, 845–53 (1925).—Absorption spectra of MeCOCH_2H (I) (b₇ 58°) in H_2O were examd. with a Hilger spectrograph, an Fe-Cu arc being used, concn. and p_{H} were varied. With diln., or with increasing alky. the concn. of the enolic form, $\text{H}_2\text{C}=\text{C}(\text{OH})\text{CO}_2\text{H}$, increased greatly (for est. of rate of increase, see original article). Attention is called to the fact that the presumably more reactive enol exists in high concns. under just those conditions which occur under biol. conditions, where I is supposed to play a part in metabolism. B. H. NICOLÉ

Mucic and allomucic acids. R. HAC AND B. HODINA. *Bull. soc. chim.* **37**, 1242–5 (1925).—A normal salt of saccharic acid, when added to a borax soln., causes the development of acidity, because of the formation of a boric complex of considerable acidity. Na mucate (I) does not behave in this manner; nor does Na allomucate (II). I and II would not be expected to act alike; either allomucic acid (IV) does not have the supposed configuration, or the configuration of the asym. C atom next to the CO_2H group is not the only factor affecting the acidity of the boric complex. Possibly *cis-trans* isomerism is involved. The presence of Cu or a compd. of Cu is necessary for the prepn. of IV from mucic acid (III) by the E. Fischer method. Analysis of III and IV by titration gives irregular results, which depend on the age of the prepn. The m. p. of III varies between 208° and 225°, depending also on the age of the prepn. M. W. MCP.

The reaction between sodium hypobromite and urea. MAXWELL BRUCE DONALD. *J. Chem. Soc.* **127**, 2255–9 (1925).—Of the numerous theories offered to explain why the reaction: $\text{CO}(\text{NH}_2)_2 + 3\text{NaBrO} \longrightarrow \text{CO}_2 + \text{N}_2 + 3\text{NaBr} + 2\text{H}_2\text{O}$, does not complete itself, only that of Fenton (*J. Chem. Soc.* **33**, 300 (1878); *Proc. Chem. Soc.* **1895**, 138) is supported by the present work of D. Neither the concn. of the NaBrO at moderate concns. nor an excess of NaBrO influences the reaction. The chief factor which influences the approach to completeness of the reaction at room temp. is the degree to which the NaOH is brominated. The effect of this was studied for bromina-

tions from 0 to 100%. The reaction is incomplete because of the formation of NaOCN. The amt. of NaOCN formed increases with increase in the ratio NaBrO/NaOH until it corresponds to 75% bromination, when it is oxidized by a secondary reaction. NaCNO solns. are not appreciably oxidized by 75–90% NaBrO solns. except when CO(NH₂)₂ is present. With NaBrO contg. no excess NaOH, NaOCN solns. are vigorously decompd. and the expts. of Margosies and Rose (C. A. 17, 3520) showing that NaOCN is not formed, are inconclusive since they did not take into account the effect of the compn of the NaBrO. The use of 10 N NaOH for estg. CO(NH₂)₂ gasometrically gives inaccurate results, and it is preferable to est. the NaBrO decompd. by adding the CO(NH₂)₂ to the NaBrO, shaking some time, dilg., adding 3 N HCl and aq. KI and titrating with Na₂S₂O₃ (starch), the difference in the Na₂S₂O₃ for this titration and for the NaBrO alone giving the equiv. quantity of NaBrO consumed. C. C. DAVIS.

Action of phenyl isocyanate on methylurea. H. BILTZ AND A. BECK. *Ber.* 58B, 2187–90(1925).—By the action of PhNCO on MeNHCONH₂, B and Jeltsch obtained a methylphenylbiuret, m. 183° (I), in which the Ph must be in the ω -position and it was assumed that the Me was in the ω' -position (C. A. 18, 529). Gatewood, however, synthesized the true PhNHCONHCONHMe (II) and found it to m. 133° and to be certainly different from I (C. A. 19, 972); moreover, in attempting to repeat the work of B. and J. she was never able to obtain their I but only her II. B. and B. have now made a renewed study of their reaction and find that at 80–90° the product is in fact II but if a large excess of PhNCO is used I first crystals from the heated mixt., on cooling, and the filtrate then yields II in greater amt. G. was able to obtain I from PhNHCONHCONH₂ with Me₂SO₄ and, as it differs from II, assigned to it the structure PhNHCONHCONH₂, a conclusion now confirmed by B. and B. According to earlier experience the alphanido groups of biurets can be nitrosated but not their amido groups, and 1 g. II in cold MeOH with N₂O₃ gives 0.7 g. ω -phenyl- ω' -methyl- ω' -nitrosobiuret, decomp. 126°, gives a positive Liebermann reaction, while I remains unchanged under the same conditions. C. A. R.

3-Ethyluric acid and 3-ethylxanthine. HEINRICH BILTZ AND ERNST PEUKERT. *Ber.* 58B, 2190–9(1925).—*o*-Cyanooethyl- ω' -ethylurea (16 g. from 10 g. EtNHCONH₂, 10 g. NCCl₂CO₂H and 20 g. Ac₂O at 75°), m. 167°, soly. in boiling H₂O about 6 (parts in 100), 10 g. with NH₄OH on the H₂O bath gives 6.5 g. 1-ethyl-6-aminouracil, decomp. 282°, soly. in hot H₂O about 2, 10 g. of this with NaNO₂ at 60° slowly treated with AcOH gives 11 g. of the 5-NO deriv., decomp. 249°, soly. in hot H₂O about 1, easily sol. in acids and, with yellow color, in alkalies, forms an *NH₄ salt*, decomp. 255°, which is stable for several days in the air when dry but when moist regenerates the free NO compd. From 10 g. of the NO compd. heated 0.5 hr. at 80° in freshly prepd. (NH₄)₂S is obtained 7 g. 1-ethyl-5,6-diaminouracil, yellow, begins to darken 250°, decomp. 270°, soly. in hot H₂O about 0.8 with yellow color and green fluorescence, insol. in acids and alkalies, readily regenerates the NO compd. in the air. 1-Ethyl-6-aminouracil-5-ethylurethan (6.5 g. from 5 g. of the di-NH₂ compd. in 2 N HCl and ClCO₂Et slowly treated with NaOH), soly. in hot H₂O about 0.67 with faint greenish fluorescence, changes at 230–40° into 3-ethyluric acid (I), prisms with 1 H₂O, slowly decomp. 360°, soly. in hot H₂O 1:190, gives with CH₂N₂ its own wt. of 3-ethyl-1,7,9-trimethyluric acid, m. 240°, sublimes at higher temps. 3-Ethyl-5(4)-chlorouric acid (II), from I in cold AcOH-Ac₂O with Cl, very hygroscopic, reddens from 150° on, extraordinarily unstable towards H₂O, traces of which produce deliquescence and decompn.; Et₂O exts. nothing from the aq. soln. of the resulting sirup, hence no caffolide is formed in the decompn. On the other hand, 0.5 g. of II in H₂O with H₂S gives 0.15 g. diethylalloxantine, m. 209°, giving with FeSO₄ and NH₄OH a deep blue color. II is, therefore, decompd. by H₂O into urea and ethylalloxan. With 10% KI, 0.3 g. II at once gives I and 0.2 g. I. 3-Ethyluric acid glycol Me hemiether (0.3 g. from 0.5 g. freshly prepd. II under 5 cc. cold anhyd. MeOH evapd. in a vacuum desiccator), slightly reddens from 180° up, decomp. 195°, soly. in boiling H₂O about 5, 0.3 g. with fuming HI and PH₃I on the H₂O bath gives 0.1 g. hydantoin. Et hemiether, reddens 160°, decomp. 189°, soly. in boiling H₂O about 5. Even in anhyd. MeOH-C₆H₅N cooled with ice-salt or solid CO₂, II does not give the glycol di-Me ether but only the hemiether, and the same is true of I and anhyd. MeOH treated with Cl. 3-Ethyl-8-chloroxanthine (III) (4 g. from 5 g. I heated 12 hrs. with POCl₃ at 130–5° in sealed tubes, evapd. *in vacuo* and refluxed in anhyd. alc.), decomp. 295°, soly. in boiling H₂O about 0.77, easily sol. in AcOH, dil. alkalies and NH₄OH, reprecipd. by mineral acids, dissolves in hot mineral acids (e. g., 30% HClO₄) and seps. unchanged on cooling, regenerates I with hot alkalies, even when very dil. (0.2 N NaOH); with fuming HI and PIH₄ it yields 3-ethylxanthine, reddens 275°, decomp. 299°, soly. in hot H₂O about 0.4, sol. in mineral acids, alkalies and NH₄OH.

3-Ethyl-8-thiouric acid (3 g. from 3 g. **III** and KSH on the H_2O bath and subsequent acidification with HCl), decomps. $365-70^\circ$, soly. in hot H_2O about 2, sol. in alkalis and NH_4OH at room temp., in dil. mineral acids on heating. *3-Ethyl-1,7-dimethyl-8-chloroxanthine* (**IV**), from **III** with $NaOH-Me_2SO_4$, m. 112° , soly. in hot H_2O about 7, only slightly sol. in 10% $NaOH$, dissolves in Me_2SO_4 , 1 g. with HI gives 0.5 g. *3-ethyl-1,7-dimethylxanthine*, m. 128° , whose perchlorate explodes violently above 300° . *3-Ethyl-1,7-dimethyl-8-thiouric acid* (0.8 g. from 1 g. **IV** with KSH), m. 272° , easily sol. in alkalis and NH_4OH and reprecipitated by acids, also dissolves in hot dil. mineral acids. In KOH with $EtBr$ in sealed tubes at 100° , 1 g. **III** gives 0.7 g. *3,7-diethyl-8-chloroxanthine*, m. 238° , easily sol. in alkalis and mineral acids, converted by boiling dil. $NaOH$ into *3,7-diethyluric acid*, m. 350° , while 1 g. with HI and PI_4I gives 0.5 g. *3,7-diethylxanthine*, m. 183° , sublimes at higher temps., easily sol. in acids and alkalis. C. A. R.

The yellow wing pigment of the brimstone butterfly (*Gonepteryx rhamni*). HEINRICH WIELAND and CLEMENS SCHOPF *Ber.* **58B**, 2178-83 (1925); cf. Hopkins, *Nature*, **45**, 581 (1901-2). The air-dried wings of 500 male butterflies (7.4 g.) were freed of fat and wax in a Soxhlet with Et_2O , then twice digested 4 hrs. in cold 2 N NH_4OH and the exts. concd. *in vacuo* over KOH and H_2SO_4 . The residue was rubbed up 4 times with H_2O and centrifuged and the crude dirty yellow pasty pigment (*xanthopterin*(**I**)) extd. with 20% HCl and pptd. with $NaOAc$, the soln. and pptn. being repeated once more and the **I** washed free of acid and halogen by repeatedly rubbing with H_2O and centrifuging. The **I** so obtained is an amorphous, hygroscopic, ochre-yellow mass, practically insol. in H_2O but easily sol. in dil. NH_4OH and $NaOH$ with yellow color and in excess of 2 N HCl without color. Neither the alk. nor acid solns. nor the aq. soln. obtained by acidifying a very dil. NH_4OH soln. with AcOH fluoresces, but a green fluorescence appears when the **I** is dissolved in a little hot H_2O or the Ba salt is repeatedly recrystd. from H_2O . The aq. soln. of **I** does not redden litmus. **I** is ash-free and has the compn. $(C_8H_5O_2N_4)_n$. Yield, about $\frac{2}{3}$ mg. per butterfly. *Ba salt*, $C_8H_5O_2N_4Ba \cdot 3H_2O$, intensely lemon yellow needles (a photomicrograph of which is given), does not lose in wt. in a microdesiccator even at 140° ; from 23.4 mg. of this salt in 5 cc. dil. HCl added to 2 g. recrystd. $NaOAc$ in 50 cc. H_2O and allowed to stand some days was obtained 8.1 mg. **I** in thick, round, orange-brown cryst. aggregates (photomicrograph) which lose 7-10% in wt. in a microdesiccator at 110° , gradually darken from 270° on and slowly carbonize from about 360° but do not melt 410° . **I** gives the murexide reaction, although not as intensely as an equal wt. of uric acid, it is apparently quite stable towards concd. HCl, is easily attacked by oxidizing agents (Br , H_2O_2) and is reduced by Zn dust in acid or alk. soln. to a leuco compd. pptd. by AcOH or $NaOAc$ in colorless flocks. The structure $\left[\begin{array}{c} NH \cdot CO \cdot CH \cdot N \cdot C \\ CO \cdot NH \cdot CH \cdot NH \end{array} \right]_2$ is suggested for **I**. C. A. R.

Products of condensation between glucose and *p*-phenetidine. **I.** MARIO AMADORI. *Atti accad. Lincei* [6] **2**, 337-42 (1925).—Irvine and Gilmour (*C. A.* **4**, 747) heated *p*-phenetidine (**I**) and glucose (**II**) with 83% $EtOH$ and obtained a compd. (**III**) $C_{14}H_{21}O_6N$. A. found that 2 compds. are obtained from **I** and **II**. In the 1st series of preps., the **I** and **II** were allowed to react in boiling $EtOH$ and in the cold **III**, m. 118° , was obtained without H_2O of crystn. In the 2nd series of preps. **I** and **II** were first heated at $50-80^\circ$. The mixt. melts and then solidifies. The mass is easily sol. in hot $EtOH$ and on cooling seps. a compd. (**IV**) m. 155° . **IV** was also obtained without heating the mixt. 9.6 g. **I** + 12.5 g. **II** with 70-100 g. 99% $EtOH$ were heated 3 hrs. After cooling the soln. is seeded with **III** and 70% of **III** seps. **I** and **II** reacting in various ratios gave the same product. **III** was prepd. by the method of I. and G. and sepd. with 1 mol. of H_2O ; from 99% $EtOH$ it sepd. in the anhyd. form, m. 118° . **IV** was obtained as stated and also from the mother liquors of **III**. **IV** is an isomer of **III** and was described by Claus and Ree (*C. A.* **7**, 2431). E. J. WITZEMANN

Constitution of lichenin and of cellulose. HANS PRINGSHEIM, WERNER KNOLL and ERICH KASTEN. *Ber.* **58B**, 2135-43 (1925).—Lichenin (**I**) heated in glycerol at 210° is broken down into its elementary substance, *lichosan* (**II**), which, obtained in 30% yield, is an amorphous powder appreciably sol. in cold H_2O , forming a true soln. Its inability to cryst. is due to the fact that in the only solvent of it (H_2O) it soon again associates; after a few hrs. the soln. becomes turbid and in a couple of days, especially in the ice chest, sets to a gel corresponding to the original **I** which, after pptn. with alc., yields a ppt. now sol. only in hot H_2O . Röntgen-spectroscopic examn. of the original **I** and of the polysaccharide regenerated from the **II** shows 3 very broad interference rings at $5^\circ 45'$, $10^\circ 6'$, $13^\circ 24'$, and at $5^\circ 50'$, $10^\circ 15'$, $13^\circ 20'$, resp.; the very faint

bands at $17^{\circ} 25'$ and $21^{\circ} 25'$ in the original **I** are not visible in the associated **II**, but the comparison indicates that the 2 substances are identical. This shows that as in the case of inulin (C. A. 18, 2527) in the degradation with glycerol no change in the constitution of the structural mol. occurs. A further confirmation of this conclusion is the fact that both **I** and **II** are optically inactive in H_2O . Acetolysis of **II** under the same conditions as with **I** (Karrer and Joos, C. A. 17, 3323) gives octaacetylbirose. Unlike the other hitherto known glucose anhydrides, **II** is fermented to glucose by dialyzed malt ext. Attempts to obtain cellobiose with a cellobiase-free malt ext. have not thus far given decisive results, as it has not yet been possible satisfactorily to sep. lichenase from cellobiase by adsorption. Assuming structural identity of **I** and **II** and since almost completely methylated **I** yields 2,3,6-trimethylglucose, **II** can be only a glucose (1,4)(1,5)-anhydride, $O.CH.CH(OH).CH(OH).CH.CH(CH_2OH).O$. In its ability to take up

Me, too, **II** behaves like **I**; the di-Me stage is reached only after 4 operations. New evidence of the analogous chem. behavior of **I** and cellulose (**III**) is found in the action of cold concd. HCl. **I** allowed to stand, with stirring, 4 hrs. at room temp. with 37% HCl, then concd. *in vacuo* over KOH, freed from the rest of the HCl with Ag_2CO_3 and pptd. with alc. gives a *biose A* (**IV**) with $[\alpha]_D^{20} 36^{\circ}$ and after 4 days a *biose B* (**V**) with $[\alpha]_D^{20} 110^{\circ}$. From **III** treated with superconc. HCl according to Willstätter and Zechmeister (C. A. 7, 3412) and pptd. with ice before it has been completely degraded to H_2O -sol. products is obtained a substance which does not reduce Fehling solu. and which with 37% HCl gives **V**; **IV** is obtained with 37% HCl from **III** pptd. from its Cu-ammine soln. with HCl (this also gave **V** on long continued treatment with fuming HCl). **IV** has the same optical activity as cellobiose but differs from it in having a materially weaker reducing power and in that, like **V**, in the osazone reaction under the influence of dil AcOH it always yields glucosazone. Attempts to apply the glycerol degradation to **III** led to no results with previously untreated **III** and to uncertain results with Cu-ammine **III**. Cellulose A (Hess, Weltzien and Messner, C. A. 18, 1384) on energetic degradation with glycerol gives, in poor yield, a H_2O -sol., non-reducing, optically inactive depolymerizate. Mol. wt. of **II** in H_2O 190, 177 (c 0.72, 0.99, resp.). Acetate of **II**: mol. wt. in PhOH, from 316 for c 1.001 to 446 for c 2.36; $[\alpha]_D^{20} -31.7^{\circ}$ to -32.7° ($CHCl_3$). Mol. wt. of **IV** from **I**, in H_2O 350, 361 (c 1.136, 1.660), reducing power 25% that of cellobiose; acetate, $[\alpha]_D^{20} 43.5^{\circ}$ ($CHCl_3$). **V** from **I**, mol. wt. in H_2O 340, 313 (c 0.67, 0.37), $[\alpha]_D^{20} 108.7$ - 112° (H_2O), reducing power 9% that of cellobiose; acetate, $[\alpha]_D^{20} 114.6^{\circ}$ ($CHCl_3$). **V** from **III** previously treated with superconc. HCl, mol. wt. in H_2O 338 (c 1.055), $[\alpha]_D^{20} 102^{\circ}$ (H_2O). **IV** from Cu-ammine **III**, mol. wt. in H_2O 386 (c 1.954), $[\alpha]_D^{20} 36.4^{\circ}$ (H_2O); **V**, mol. wt. 361 (c 1.942); $[\alpha]_D^{20} 104.4^{\circ}$. C. A. R.

Odor and molecular asymmetry. **II.** JULIUS V. BRAUN AND WILHELM TEUFFERT *Ber* 58B, 2210-5(1925); cf. C. A. 18, 969.—Et 3-methyl-1-hydroxycyclohexylacetate Wallach and v. B., *Ann.* 414, 168(1901)), b_{18} 126-8°, d_4^{15} 1.004, $[\alpha]_D 1^{\circ} 44'$; the inactive ester has the same b. p. and d. Both esters, heated 3 hrs. at 160° with 2 parts $KHSO_4$, are dehydrated and partially sapond., giving about 40% of the unsatd. ester and 30% of the acid. Active Et 3-methyl-1-cyclohexenylacetate, b_{18} 107-9°, d_4^{14} 0.9644; acid, b_{18} 116°, d_4^{14} 1.0253. Inactive ester, b_{18} 107-10°, d_4^{16} 0.9626; acid, b_{18} 146°, d_4^{16} 1.023. The unsatd. esters are almost quant. hydrogenated in MeOH with H and Pd to the satd. esters. Inactive Et *m*-methylcyclohexylacetate, b_{18} 107-10°, d_4^{14} 0.9338, n_D^{14} 1.4434, hydrolyzed by aq. alc. alkali to the acid, rather thick liquid of faint odor, b_{18} 148°, d_4^{15} 0.9911, n_D^{15} 1.4607. Active ester, has the same b. p. as the inactive ester, d_4^{15} 0.9322, n_D^{15} 1.4442, $[\alpha]_D -7^{\circ} 25'$; acid, same b. p. as the inactive form, d_4^{20} 0.9847, n_D^{20} 1.4595, $[\alpha]_D -9^{\circ} 26'$. Both esters have a strong fruity odor which, however, is so little characteristic that a difference between the 2 cannot well be established. Bromination of the 2 satd. acids with Br and P and treatment with abs. alc. gives 70% of the Et *m*-methylcyclohexylbromoacetates, b_{18} 139-40°, faintly yellow liquids of pleasant odor; inactive ester, d_4^{16} 1.255, n_D^{15} 1.4771; active ester, d_4^{18} 1.2528, n_D^{18} 1.4775, $[\alpha]_D -6^{\circ} 3'$. Heated 100 hrs. in dry C_6H_6 with 2.5 mols. $NHMe_2$ they give 60% of the Et *m*-methylcyclohexyldimethylaminoacetates, liquids of strong basic odor, b_{18} 127°; inactive ester, d_4^{20} 0.943, n_D^{16} 1.4544; active ester, d_4^{20} 0.9398, n_D^{20} 1.4553, $[\alpha]_D -5^{\circ} 13'$; the hygroscopic HCl salts, m. 189° and 187°, resp., and the methiodides 177° and 161°; the picrates are oily. The Ladenburg reduction with well-dried alc. and a 2.5-fold excess of Na gives

70% of the β -*m*-methylcyclohexyl- β -dimethylaminoethyl alcs., b_{16} 128°; inactive alc., d_4^{18} 0.9351, n_D 1.4740 (picrate, oily; *HCl* salt, very hygroscopic; methiodide, m. 173–4°); active alc., d_4^{18} 0.9351, n_D^{18} 1.4742, $[\alpha]_D$ –6° 10' (picrate, oily; *HCl* salt, hygroscopic; methiodide, m. 160–1°). The methiodides, treated with Ag_2O , evapd. to dryness *in vacuo* and heated over a free flame, give 60% of the *m*-methylcyclohexylethylene oxides, b. 72–3°; inactive oxide, liquid of pleasant ethereal odor, d_4^{18} 0.9165, n_D^{18} 1.4527, slowly gives a very faint pink color with fuchsin- SO_2 ; active oxide, has an odor similar to but milder than that of the inactive form, d_4^{18} 0.9165, n_D^{18} 1.4527, $[\alpha]_D$ –10° 54'. Heated 4 hrs. at 160–70° with 10 parts H_2O both oxides give about 50% of the glycols, b_{16} 138–40°, which are converted by H_2SO_4 into the *m*-methylcyclohexylacetaldehydes.

Dihydrazines. VI. Further experiments in the sugar series with diphenylmethanedimethylhydrazine. JULIUS v. BRAUN AND OTTO BAYER. *Ber.* 58B, 2215–22 (1925); cf. *C. A.* 4, 2639; 8, 924; 11, 2785.—It has been shown that (*p*- $H_2NNMeC_6H_4$)₂- CH_2 (I) reacts in a markedly different way with different sugars (e. g., ketoses do not react with it at all and of the aldoses only those react in which at least 2 adjacent CHOH groups of the 3 following the aldehyde radical have the same configuration). The present paper is a report of a study of the use of I in the prepn. of sugars by taking advantage of the rearrangement which monosaccharides, according to the work of Lobry de Bruyn and his pupils, undergo under the influence of HO ions in very small concns. (dil. alkalis, $Pb(OH)_2$). Under such conditions an aldose gives, together with ketoses, which do not react with I, an epimeric aldose; if the original aldose does not react with I, the rearrangement product should, so that from such a mixt. the new aldose should easily be isolated by means of I, provided it can be regenerated from the dihydrazone; if both aldoses react with I, they still might be simply sepd., after removal of the ketoses and either before or after regeneration from the hydrazone mixt., by some difference in their properties (e. g., on fermentation). Two points had first to be settled: (1) Is it possible to regenerate at all smoothly the sugar from the extraordinarily difficultly sol. dihydrazones? (2) Since with a soln. of unknown aldose content a considerable excess of I must always be used, is it possible that instead of or along with dihydrazones of the type $CH_2(C_6H_4NMeN:R)_2$ (II) (R = sugar residue) the easily sol. hydrazones of the type $R:NMeC_6H_4CH_2C_6H_4NMeNH_2$ (III) are also formed and escape detection? Both questions have been answered satisfactorily. With arabinose, mannose and galactose, hydrazones of type III are formed, to be sure, when a large excess of I is used, but in much smaller amt. than those of type II, and although they are much more sol. in alc., they are quite insol. in dil. AcOH. Regeneration of the sugar from the dihydrazones is a more difficult matter; it cannot be effected with HCl , BzH , enanthial, etc., nor even with aq. $HCHO$, and only $HCHO$ solns. contg. much C_6H_5N proved effective, owing to the much greater soly. of the dihydrazones in this medium. With glucose, fructose or invert sugar v. B. and B. were able to obtain easily and in about the amts. detd. by L. de B. the only sugar (mannose) which reacts with I. In the case of *d*-galactose, both it and its epimer, *d*-talose, would be expected to react with I and such proved to be the fact, but as talose is not fermentable, the unchanged galactose was fermented away and the talose was easily sepd. by means of I from the ketoses formed by the action of the alkali, thus making it now a comparatively readily available sugar. Galactose in dil. AcOH with 5 mols. I gives after 1 hr. a mixt. sepd. by means of C_6H_5N -alc. into the insol. dihydrazone (II), m. 215° (yield, 75% of the calcd.) and 24% of the sol. *mono-compd.* (III) (pptd. by H_2O from the concd. soln.), m. 175°. With 2 mols. I the yield of the III is 20% and with 1 mol. 13%. Arabinose with 6 mols. I gives 15% of the *mono-compd.*, m. 155°; with 2 mols., 5%. Mannose gives, even with a large excess of I, only traces of the *mono-compd.*, m. 165°. The optimum conditions for the regeneration of the sugar from the dihydrazones are 10 parts dihydrazone, 25 vols. C_6H_5N , 25 vols. H_2O and 15 vols. of 30% $HCHO$ warmed over a small flame until clear and then 0.5 hr. on the H_2O bath. Arabinose in this way was recovered in 62% yield, galactose in about 30% yield. From 100 g. galactose heated 1 hr. at 100° with $Pb(OH)_2$ and then treated as outlined above is obtained 5–7 g. *talose dihydrazone* (II), faintly brownish powder, m. 185°: the free talose (2–3 g.), light sirup which could not be made to cryst., shows, contrary to previous observers, *l*-rotation (–32.5° in 0.5% soln. in a 0.5-dm. tube), whence it is to be represented as *d*(–)-talose; its whitish yellow phenylhydrazone m. 178° (decompn.); *p*-bromophenylhydrazone, yellow, m. 205°; benzylphenylhydrazone, faintly yellowish, m. 199°; methylphenylhydrazone, m. 220–2° (Blanksma and van Ekenstein, *C. A.* 3, 779, give 154°).

C. A. R.

Rule of alternation of radicals in aromatic derivatives. J. PASTAK. *Rev. gén. sci.* 36, 70-6(1925).—Radicals are divided into 2 classes: basic, H, alkyl, Cl, Br, OH, NH₂; acid, HSO₃, NO₂, CO₂H, N:NAr, Cl, Br, etc. Substituents of the same class as the group already present, enter *meta*; those of a different class enter *ortho* or *para*. P. finds it necessary to include halogens in both groups to explain results consistently. No new exptl. work is given. B. H. NICOLET

Some derivatives of toluene. RAOUL POGGI. *Atti accad. Lincei* [6], 2, 423-7 (1925).—Some new derivs. of PhMe are described. 1-Iodomethyl-3-nitrobenzene, obtained by boiling the corresponding Cl compd. in EtOH with a slight excess of KI, yellowish, m. 84.5-86°. 1-Iodomethyl-2,4-dinitrobenzene, m. 75.5-76°, was obtained similarly from the Cl deriv. (cf. Jackson and Whitmore, *C. A.* 9, 2531). *p*-O₂NC₆H₄-CH₂SCN treated with 10 parts of concd. H₂SO₄ for 6 hrs. at 0° and then poured into ice H₂O sepd. the *p*-nitrobenzyl mono-thiocarbamate, O₂NC₆H₄CH₂SCONH₂, m. 140-1°, boiled with 20% HCl, H₂S, NH₃, CO₂ and *p*-O₂NC₆H₄CH₂SH, m. 55°, are formed. *m*-NCC₆H₄Me brominated at 160° by Sandmeyer's method gave 1-bromomethyl-3-cyanobenzene, m. 94-5.5°. This compd. with KCNS gave the corresponding thiocyanate deriv. (Hörllich, *Ber.* 34, 3370(1901)). 1-Iodomethyl-3-cyanobenzene, m. 113-4° and 1-iodomethyl-2-cyanobenzene, m. 77-8°, were obtained by boiling the corresponding Cl compds. with KI in EtOH; *p*-CNC₆H₄CH₂Cl boiled 0.5 hr. with Na₂S₂O₅ in 50% EtOH sepd. on cooling the thiosulfate NCC₆H₄CH₂S₂O₂Na, which in concd. H₂SO₄ at 70° gave *p*-cyanobenzyl mercaptan (I) NCC₆H₄CH₂SH as an oil that solidifies, m. 43°. I oxidized with I in EtOH gave the corresponding disulfide, m. 147.5°. E. J. W.

Syntheses in the aliphatic-aromatic series. XV. *o*- γ -Bromopropylbenzyl bromide. JULIUS V. BRAUN and WILHELM KAISER. *Ber.* 58B, 2162-4(1925); cf. *C. A.* 18, 829; 20, 391.—*o*-ClCH₂CH₂CH₂C₆H₄CN with 1.3 atoms Na in boiling alc. gives almost 90% of the cyano ether EtO(CH₂)₃C₆H₄CN, slightly yellow liquid of faint odor, b₁₆ 150°, which in decalin at 100° with N under 30 atm. yields almost 60% of the amine EtO(CH₂)₃C₆H₄-CH₂NH₂ (I), b₁₄ 155-8°, quickly absorbs CO₂ from the air; *HCl salt*, m. 112°. Together with I is formed about 0.5 its wt. of a fraction b₁₄ 180-280°, which on repeated distn. yields more I (bringing its total yield to above 70%) and a N-free substance which is probably C₆H₄.CH₂.CH₂.CH(OEt).CH₂. In AcOH with NaNO₂ I gives 90%

of the HO ether EtO(CH₂)₃C₆H₄CH₂OH (II), mobile, almost odorless liquid, b₁₆ 165-70° (still slightly impure; found, C 73.63, H 9.34%). When II is heated 4 hrs. in a sealed tube at 100° with 6 parts of 60% HBr it yields a faintly yellow oil, b₁₆ 168-75°, affecting the eyes like PhCH₂Br, whose Br content indicates that a Br atom has, for the most part, replaced the 6-HO group, but the product is not homogeneous and already contains about 20% of the dibromide; if the heating is continued 17 hrs., much EtBr is evolved and the Br content of the product rises to almost 51% (calcd. for *o*- γ -bromopropylbenzyl bromide (III), 54.74%); another 5 hrs. heating gives products b. 175°, with almost 54% Br, which may be considered as practically pure III; they are heavier than H₂O, irritate the mucous membranes, are faintly yellow and can be distd. without decompn. but cannot be crystd. Heating longer than 22 hrs. results in secondary reactions; the b. p. rises, the Br content increases beyond 55% and much less homogeneous products are obtained. With 2 mols. NHMe₂ in C₆H₆, III evolves heat and yields almost quant. *asym*-homotetrahydroisoquinoline methobromide, m. 241-2°; chloroplatinate, m. 257-8°. C. A. R.

Cyclic sulfides. III. JULIUS V. BRAUN. *Ber.* 58B, 2165-8(1925); cf. *C. A.* 5, 696.—It has been pointed out that the tendency to the formation of a polymethylene sulfide, (CH₂)_nS, from Br(CN)_nBr and S runs approx. parallel to the tendency to the formation of a N ring with 1 more CH₂ group, (CH₂)_{n+1}NR, whereas in the benzo derivs. of the polymethylene imines the differences in the tendency to the formation of the individual derivs. of the series practically disappear. In the present paper it is shown that in the benzopolymethylene sulfides the no. of members in the S ring does not have a marked influence on the ring formation but, unlike the imines, the direct or indirect union of the S to the aromatic nucleus does. *o*-Xylylene sulfide, obtained in 40% yield from C₆H₄(CH₂Br)₂ in alc. with 1.5-3.0 mols. aq. Na₂S on the H₂O bath, b₁₄ 108°, m. 26°, is stable for months when protected from the air, d₄²⁶ 1.143, has a thiophene-like odor, becomes discolored rapidly in the air; methiodide, m. 175° (Hjelt, *Ber.* 22, 2904(1889), gives 155°) and is snow-white. 2,3-Dihydrothionaphthene, obtained almost quant. from diazotized *o*-ClCH₂CH₂C₆H₄NH₂.HCl and KOCS₂Et and subsequent heating with alc. KOH, faintly yellow, b₁₁ 104°, d₄²¹ 1.129, has a styrene-like odor, adds MeI with exceeding sluggishness, is oxidized by the calcd. amt. of KMnO₄ to the sulfone, m. 98°, and

with 1.1 atoms S at 200° gives H₂S and thionaphthene. *Homoisothiochroman*, obtained in only 40% yield from *o*-Br(CH₂)₂C₆H₄CH₂Br (preceding abstr.) and Na₂S, b₁₄ 141–5°, m. 95–6°; *methiodide*, m. 154°; *sulfone*, m. 176°.
C. A. R.

The introduction of two atoms of bromine in *m*-acetotoluidide. S. C. J. OLIVIER. *Rec. trav. chim.* **44**, 1109–12(1925).—*m*-Toluidine treated in AcOH with 2 mols. of Br gave much tribromotoluidine (I). When a 6–7% soln. of aceto-*m*-toluidine in AcOH was treated with 2 mols. of Br₂, no I was formed, but 93% of a mixt. of 2 isomeric di-Br derivs., m. 30–5°, was obtained. This crystd. from EtOH first sepd. a 4,6-dibromo-3-acetamino-1-methylbenzene (II), m. 171.5–2.5°, which on sapon. gave the *free base* (III), m. 76–7°. III oxidized (cf. C. A. **19**, 1259) gave 2,4-Br₂C₆H₃CO₂H, thus proving its constitution. The mother liquors from II gave 2,6-di-Br isomer (IV) of II, m. 117–28°, of which the *free base* (V), m. 66.5–67°. The latter on oxidation gave 2,6-Br₂C₆H₃CO₂H, m. 150–1°, thus proving the constitution of IV. The m. p. diagram for mixts. of II and V was detd. The crude product was thus found to contain 73% of III and 27% of V. The product m. 33–5° obtained by Neville and Winter (*Ber.* **13**, 971(1880)) was a eutectic mixt. of III and V.
E. J. WITZEMANN

The reaction between methanol and phenol at high temperature and under pressure. Preliminary paper. V. IPATIEV, I. ORLOV AND G. RAZOUBAIEV. *Bull. soc. chim.* **37**, 1576–7(1925).—When 1 part of PhOH is heated in the presence of Al₂O₃ in the app. of I. for 24 hrs. at 44° and 200 atm. with 6 parts of MeOH, there result *o*-HOC₆H₄Me and small quantities of PhH and its homologs and a little PhOMe. Expts. with EtOH give similar results. PhOMe is probably an intermediate product. Heated under similar conditions it gives *o*-HOC₆H₄Me.
REYNOLD C. FUSON

Some ketonic alcohols of the general formula PhCH(OH)COR. TIFFENEAU AND J. LEVY. *Bull. soc. chim.* **37**, 1247–51(1925).—T. and L. studied the prepn. and properties of PhCH(OH)COR in which R = Me, Et, Pr, iso-Pr, Bu, iso-Bu and benzyl. These were prepd. by the action of alkyl-MgBr or alkyl-MgI on PhCH(OH)CONH₂ (I) or PhCH(OH)CN (II), preferably I because pure products were more easily obtained from it. They reduce hot Fehling soln., are usually volatile in steam, give cryst. semicarbazones, sometimes give solid oximes and give, with org. Mg derivs., secondary tertiary glycols. I, m. 132°, was obtained from NH₃ and PhCH(OH)CO₂Et. II was obtained from NaCN and the bisulfite compd. of BzH. From I was obtained PhCH(OH)COEt (III), b₁₁ 124–8°, m. about 32–3°, in 40% yield; from II, in 27% yield. Semicarbazone, m. 89–90°, gives III with H₂SO₄. Oxime, m. 97°. From I was obtained PhCH(OH)COiPr (IV), b₂₈ 159–62°, d₄ 1.064, in 30% yield. Semicarbazone, m. 157–8°. From I was obtained PhCH(OH)COCHMe₂, b₃₈ 160–70°, m. 44–5°, in 28–30% yield; from II, in 20% yield. Semicarbazone, m. 158–9°. From I was obtained PhCH(OH)COBu, b₁₈ 145–60°, d₄ 1.045, in 20% yield; from II, in 12% yield. Semicarbazone, m. 152–3°. Oxime, m. 95–6°. From I was obtained PhCH(OH)COCH₂CHMe₂, b₃₈ 155–7°, d₄ 1.048, in 17% yield. Semicarbazone, m. 123°. Oxime, m. 99–100°. From I was obtained PhCH(OH)COCH₂Ph, m. 115–6°; more easily from II, in 30% yield. Semicarbazone, m. 189–90°.
MARGARET W. MCPHERSON

Isomerization of diphenylallyl alcohol into benzylaceto-phenone. HIROSHI NOMURA. *Bull. soc. chim.* **37**, 1245–7(1925).—PhCH₂CHCH(OH)Ph (I) (21 g.), m. 56.5–7.0°, was obtained from 25 g. PhCH:CHCHO and excess PhMgBr. I decolorizes Br in CHCl₃ and also KMnO₄. Its acetate (II) b₉ 211°. I and Na and EtOH give PhCH₂CH₂COPh (III), m. 72°, whose oxime, m. 84.5–5.0°, instead of 87° or 82° as given in the literature. II and alc. KOH give III. I (2 g.) and alc. KOH give 1.9 g. III.
MARGARET W. MCPHERSON

Phenol: its synthesis, uses and derivatives. G. M. DYSON. *Chem. Age* (London) **14**, 70–3(1926).—A review.
E. H.

The alkylation of phenols. M. BUSCH. *Z. angew. Chem.* **38**, 1145–6(1925); cf. C. A. **19**, 2038.—The tendency of benzyl radicals toward C-alkylation of phenols increases with the increasing substitution of the methane C. While it is possible to obtain ethers with PhCH₂Cl in non-dissociating media, Ph₂CHCl yields only the C derivs. Of the deeply colored intermediate addn. products the red 1-hydroxy-2-diphenylmethyl-6-diphenylbromomethyl-4-benzaldehyde was isolated. On recrystn. from hot alc. it yields the colorless 1-hydroxy-2,6-bis-[diphenylmethyl]-4-benzaldehyde. PhOH homologs behave like PhOH; polyphenols are disubstituted. Of the nitrophenols *o*- does not react, *m*- forms the ether, *p*- is disubstituted. In alk. soln. all 3 give ethers. A great no. of phenols yield with Ph₂CN₂ 10–90% ether. Negative substituents seem to favor the reaction. The ethers cannot be rearranged by migration of the alkyl

into the nucleus. Polyphenols are not etherized but catalyze the decompn. of Ph_3CN_2 to diketazine.

MARY JACOBSEN

Interactions of tellurium tetrachloride and aryl alkyl ethers. I. G. T. MORGAN AND H. D. K. DREW. *J. Chem. Soc.* **127**, 2307–15(1925); cf. *C. A.* **20**, 413.—A mixt. of TeCl_4 (12 g.), PhOEt (17 g.) and dry CHCl_3 (75 cc.) heated with reflux evolved HCl and pptd. from the soln. 92% of *p*-phenetyltellurium trichloride (I), glistening yellow, m. $182-3^\circ$ to a red liquid, gives yellow solns. in hot CHCl_3 and in C_6H_6 and a colorless soln. (due to hydrolysis) in EtOH . I (6 g.) reduced at 0° with KHSO_3 (11.3 g.) and H_2O (50 cc.) yielded almost quant. *bis*-*p*-phenetyl ditelluride (II), brilliant orange-red, m. $107-8^\circ$ to a deep red liquid, gives red solns. in org. solvents, unattacked by boiling NH_4OH , decompd. by MeI and forms *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{OEt}$ when evapd. with cold concd. HNO_3 . I heated with PhOEt (1.4 by wt.) at $180-90^\circ$ evolved HCl and on addn. of petroleum pptd. *bis*-*p*-phenetyltellurium dichloride, colorless, m. 108° . The formation of I and II proves to be erroneous the data of Rust (*Ber.* **30**, 2829(1897)), Rohrbach (*Ann.* **315**, 9(1901)) and Lederer (*C. A.* **10**, 769; **11**, 2670), all of whom obtained what were supposedly $(\text{EtOC}_6\text{H}_4)_2\text{TeCl}_2$ and $(\text{EtOC}_6\text{H}_4)_2\text{Te}$. TeCl_4 (2.9 g.), *m*- $\text{C}_6\text{H}_4(\text{OMe})_2$ (III) (1.5 g.) and dry CHCl_3 (30 cc.) heated at 100° evolved HCl , forming a deep-brown-yellow soln., which on removal of CHCl_3 , stirring the resulting crystd. sirup with CCl_4 , and addn. of CHCl_3 pptd. 2.7 g. 1,3-dimethoxyphenyl-4-tellurium trichloride (IV), primrose-yellow needles or golden yellow prisms, m. $155-6^\circ$ to a yellow liquid turning immediately red, evolves III when warmed with aq. KOH . With TeCl_4 (4.2 g.), III (4.2 g.) and CHCl_3 (10 cc.) at 100° the product (4.9 g.) was a mixt. of IV and *bis*-1,3-dimethoxyphenyl-4-tellurium dichloride (V). With TeCl_4 (6.7 g.), III (1.8 g.) and CHCl_3 (12 cc.) at higher temps. a 2nd atom of Te was not introduced in the aromatic nucleus and only a mixt. of IV, V and unchanged TeCl_4 was obtained. Reduction with excess aq. KHSO_3 decompd. IV but not V, the latter being then extd. with boiling EtOH , colorless pearly, m. $204-5^\circ$, decompd. by hot aq. KOH with liberation of III. The difference in the condensation of PhOEt and of III with TeCl_4 is due to the comparative insoly. in CHCl_3 of I, which is pptd. as fast as formed. IV (1.2 g.) reduced by KHSO_3 (2.1 g.) and H_2O (10 cc.) gave quant. *bis*-1,3-dimethoxyphenyl-4,4-tellurium trichloride (VI), orange-brown needles or prisms, m. $134-5^\circ$ to a red liquid, does not react with aq. alkalis, gives an intense red-purple color with cold concd. H_2SO_4 . TeCl_4 (1 mol.), guaiacol (2 mols.) and dry CHCl_3 (5 cc. per g. of TeCl_4) at 100° evolved HCl and gave a deep yellow-green soln. which, concd. *in vacuo* and the unchanged guaiacol extd. with petroleum, gave on boiling with CHCl_3 or C_6H_6 2 products, (1) an unidentified amorphous, insol. mustard-yellow powder decompg. at about 180° and (2) 2-hydroxy-1-methoxyphenyl-4-tellurium trichloride, deep yellow, m. $157-9^\circ$ (decompn.), hydrolyzed in soln. by moist air. Reduced with aq. KHSO_3 at 0° it formed *bis*-2-hydroxy-1-methoxyphenyl-4,4-ditelluride (VII), orange-brown prisms, slowly darkens above 114° , m. $117-8^\circ$ (liberating Te), decompd. by boiling EtOH , yields with aq. NaOH or Na_2CO_3 (but not NaHCO_3) the Na salt, yellow-orange in soln., from which VII is reprecipd. by mineral acids. Addn. of $\text{ClCH}_2\text{CO}_2\text{H}$ to VII in aq. NaOH pptd. purple-blue flakes of a substance which gave a red soln. in dil. aq. NaOH but decompd. on removal from soln. *Bis*-*p*-anisyl ditelluride (VIII) (5 g.) in MeI (78 g.) heated at 100° with reflux pptd. *p*-anisyl dimethyltellurium iodide (IX), salmon-color, m. $170-2^\circ$, almost insol. in org. solvents, hydrolyzed by boiling EtOH , not reduced by aq. alkali bisulfites, decompd. by warm aq. Na picrate (contg. free picric acid) with formation of 2 products: (1) the picrate obtained by Lederer, m. $126-7^\circ$ and (2) a substance which was probably an addn. compd. of picric acid and *p*-anisylmethyl telluride, pale yellow, changes slowly at 160° and decompd. with effervescence at 176° to a clear yellow liquid. The MeI mother liquor from the prepn. of IX contained only *p*-anisylmethyltellurium diiodide (X), red, m. 109° , reduced by KHSO_3 in presence of Et_2O to *p*-anisylmethyl telluride, yellow oil with nauseating odor. Part of the X was retransformed to VIII by partial reduction, followed by intra-mol. loss of MeI , the reactions being: (1) $\text{MeOC}_6\text{H}_4\text{TeMeI} \rightarrow 2\text{HI} + \text{MeOC}_6\text{H}_4\text{TeMe}$ and (2) $2\text{MeOC}_6\text{H}_4\text{TeMeI}_2 \rightarrow 2\text{HI} + \text{MeOC}_6\text{H}_4\text{TeMeI} \cdot \text{TeMeIC}_6\text{H}_4\text{OMe} \rightarrow 2\text{HI} + 2\text{MeI} + \text{MeOC}_6\text{H}_4\text{Te} \cdot \text{TeC}_6\text{H}_4\text{OMe}$. The expts. show in several more cases (*loc. cit.*) defects in the work and conclusions of Lederer.

C. C. DAVIS

Nitration of creosol, acetylcreosol and homoveratrole. MAX OBERLIN. *Arch. Pharm.* **263**, 641–68(1925).—Nitration studies were carried out on creosol, acetylcreosol and homoveratrole, and the following new derivs. prepd. and characterized: 2,6-Dinitroacetylcreosol, $\text{C}_{10}\text{H}_{10}\text{N}_2\text{O}_7$, from acetylcreosol or 6-nitroacetylcreosol with fuming HNO_3 (d. 1.52) at 5° to 20° , m. $101-2^\circ$, converted by 10% NaOH into 2,6-dinitroacresol, $\text{C}_8\text{H}_8\text{N}_2\text{O}_6$, pale yellow granular crystals, m. $107-8^\circ$, which yield *via* Schotten-Baumann 2,6-dinitrobenzoylcreosol, $\text{C}_{18}\text{H}_{12}\text{N}_2\text{O}_7$, pale yellow, m. $111-2^\circ$;

2,6-dinitrohomoveratrole, $C_9H_9N_2O_6$, from 2,6-dinitrocreosol, 15% NaOH and Me_2SO_4 , m. 90–1°; 5-nitrocreosol, $C_8H_8NO_4$, from creosol and HNO_3 (1.52), both in cold dry Et_2O , m. 81–2°, yielding with Ac_2O 5-nitroacetylcreosol, $C_{10}H_{11}NO_6$, m. 89–90°, converted by HNO_3 (d. 1.52) into 5,6-dinitroacetylcreosol, $C_{10}H_{10}N_2O_7$, m. 151–2°, which on soln. in concd. H_2SO_4 yields 5,6-dinitrocreosol, $C_8H_8N_2O_6$, yellow, m. 163–4°. 2,5,6-Trinitrocreosol, from dry 2,6-dinitrocreosol in concd. H_2SO_4 with KNO_3 in the cold, deep yellow granular crystals, m. 83–4°, yielding with Ac_2O 2,5,6-trinitroacetylcreosol, $C_{10}H_9N_3O_8$, pale yellow, m. 109–10°, or with Me_2SO_4 2,5,6-trinitrohomoveratrole, $C_9H_9N_3O_8$, m. 100–1°, reduced by H_2S in NH_4OH to 2-nitro-6-aminohomoveratrole, $C_9H_{12}N_2O_4$, deep yellow, m. 104–5° (*Bz* deriv. $C_{10}H_{11}N_2O_6$, m. 170–1°), yielding on diazotization 2-nitrohomoveratrole, $C_9H_{11}NO_4$, b₁ 148–8.5° (decompn.) b₁ 115–7°, b_{0.5} 108–10°.

W. O. E.

The preparation of catechol-*o*-carboxylic acid and the condensation between catechol and glycerol. SN-ITI KAWAI. *Bull. Inst. Phys. Chem. Res.* 5, 47–9 (1926).—Five g. of catechol are mixed well with 20 g. of $KHCO_3$ in a mortar, then with 15 g. of glycerol, dehydrated at 170°, and poured into a Cu flask of 500 cc. After 1 day the mixt. is heated in a Victor Meyer dryer in a current of CO_2 for 16.5 hrs., $PhOH$ being used as a heating liquid. After cooling the reaction product is dissolved in HCl and extd. with Et_2O , which is then washed with $KHCO_3$ soln. several times. From the alkali soln., 1.6 g. of 1,2-dihydroxybenzene-3,6-dicarboxylic acid and 3.37 g. of catechol-*o*-carboxylic acid are isolated. From the Et_2O soln., 1.47 g. of catechol and 0.09 g. of catechyl glyceryl ether are obtained. By treating 5 g. of catechol, 10 g. of $KHCO_3$ and 70 g. of glycerol by the same method, 0.49 g. of catechol-*o*-carboxylic acid, 0.34 g. of catechol and 4.45 g. of catechyl glyceryl ether is obtained. By the same method, no reaction is observed between pyrogallallic acid and glycerol and between mannitol and catechol.

K. K.

A practical method for the preparation of perbenzoic acid. J. LÉVY AND R. LA-GRAVE. *Bull. soc. chim.* 37, 1597–600 (1925).— Bz_2O_2 in $PhMe$ is treated with $EtONa$ at –5°. The resulting BzO_2Na gives 85% of BzO_2H when treated with acid in the cold.

REYNOLD C. FUSON

The chlorination of *o*- and *p*-aminobenzoic acids. L. ELION. *Rec. trav. chim.* 44, 1106–8 (1925).—The prepn. of 3,5,2- $Cl_3(H_2N)C_6H_3CO_2H$ (I) from anthranilic acid with SO_2Cl_2 was described by Eller and Klemm (*C. A.* 16, 2317) and Durrans (*C. A.* 17, 2875). The following method is more convenient: com. anthranilic acid was dissolved in 10 parts of $AcOH$, filtered and treated with the calcd. amt. of Cl while cooling in H_2O . A ppt. was formed at once. An equal vol. of Na_2SO_3 soln. was then added, and the ppt. was filtered off. Acidifying the filtrate pptd. 75% of I, m. 231°. I boiled 15 min. with 5 parts Ac_2O gave 3,5-dichloroacetyl anthranil (II), m. 151°. II boiled with NaOH is slowly dissolved and on acidifying the soln. 3,5-dichloro-2-acetylaminobenzoic acid, m. 203°, is pptd.; this is sapond. by HCl, giving I. In a previous paper E. (*C. A.* 17, 3488) described the prepn. of 3,5,4- $Cl_3(H_2N)C_6H_3CO_2H$ (III) by chlorination of *p*- $H_2NC_6H_4CO_2H$ in $AcOH + HCl$ with $KClO_3$. Better results are obtained in chlorinating as with I above. 35% III is obtained and much *sym*- $Cl_3C_6H_3NH_2$ (IV), indicating that the *p*- CO_2H group is more easily replaced than the *o*- CO_2H in I since in this case only a little IV is obtained.

E. J. WITZEMANN

An addition product of mandelic acid and benzene. C. W. ZAHN. *Rec. trav. chim.* 44, 1048–50 (1925). (In English).—When mandelic acid is crystd. from boiling C_6H_6 and the crystals are allowed to stand with the mother liquor for several days at room temp. a 1:1 addn. product of the acid with C_6H_6 is formed. This product is indefinitely stable at room temp. in contact with C_6H_6 but dissociates easily in air, leaving the soft white powder of ordinary C_6H_6 -free mandelic acid. It is not formed at 45° which suggested that it has a transition point lying below this temp. and this was found to lie between 32.6° and 32.7°.

E. J. WITZEMANN

Formation of coumarins from citric acid and phenols. ARNO MÜLLER. *Ber.* 58B, 2202–9 (1925).—Hydrated citric acid (I) (100 g.), 50 g. *m*-cresol and 300 g. H_2SO_4 (d 1.84) heated to 130° in the course of 25 min. yield 6.2 g. (crude product) of 4,7-dimethylcoumarin (II), m. 132° (cor.); judging from the odor, coumarone-like substances are formed at the same time. I dehydrated according to v. Pechmann (*Ann.* 261, 155) under the same conditions gives 2.8 g. crude II, 73% H_2SO_4 yields resinous products and 10% oleum gives only 1 g. crude II. *p*-Cresol gives 1 g. of crude product from which can be isolated a small amt. of leaflets having the same m. p. as 4,6-dimethylcoumarin, while *o*-cresol yields 0.6 g. of a crude product from which no cryst. substance can be isolated. I (50 g.) and 25 g. crystd. orcinol heated 30 min. at 110–30° with concd. H_2SO_4 give 40 g. of a brick-red product, from 0.5 of which is isolated about 10 g.

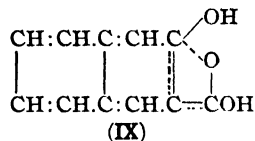

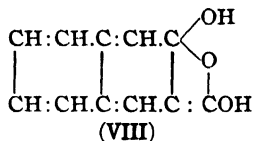

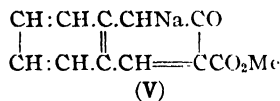

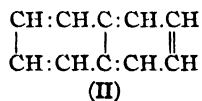

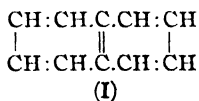

5-methylumbelliferoneacetic acid (III), difficultly sol. in hot alc., and an alc.-sol. product, orcinolaurin (IV) (obtained by Nencki, *J. prakt. Chem.* [2], 25, 277, from orcinol, HCO_2H and ZnCl_2). III was also prepd. in 7 g. yield by converting com. I (300 g.) into $\text{CO}(\text{CH}_2\text{CO}_2\text{H})_2$ (80 g.) by v. Pechmann's method (*Ann.* 261, 152) and allowing 18 g. of the latter to stand 1 day in concd. H_2SO_4 ; it is a pale yellow odorless powder difficultly sol. in most of the usual solvents except hot PhNO_2 , from which it seps. in needles, m. $267-8^\circ$ (gas evolution) on rapid heating, sol. in 10% Na_2CO_3 with golden yellow color and reprecip. by acids, gives a brown color in alc. with FeCl_3 ; heated at $300-30^\circ$ until the evolution of CO_2 ceases it gives 4,5-dimethylumbelliferone (V), m. 249° , which is best prepd. (7.3 g.) from 7 g. orcinol, 15 g. $\text{AcCH}_2\text{CO}_2\text{Et}$ and 100 g. of 73-5% H_2SO_4 heated 45 min. at $75-80^\circ$. IV is obtained directly in 3 g. yield from crystd. orcinol (2.5 g.) and HCO_2H (5 g.) heated 20 min. at $110-30^\circ$ with concd. H_2SO_4 . The condensation of orcinol with I under the influence of concd. H_2SO_4 , therefore, undoubtedly proceeds mainly according to the schemes $\text{I} \rightarrow \text{CO}(\text{CH}_2\text{CO}_2\text{H})_2 (+ \text{orcinol}) \rightarrow \text{III}$ and $\text{I} \rightarrow \text{HCO}_2\text{H} (+ \text{orcinol}) \rightarrow \text{IV}$. That V can be formed directly from I and concd. H_2SO_4 is highly improbable; 100 g. I heated 1 hr. at 130° with 300 g. concd. H_2SO_4 gave a small amt. of a green fluorescent dye having the properties of IV and a substance difficultly sol. in alc. and apparently identical with III. Attempts to prep. a toluidi- $[\beta\text{-methyl-}\alpha\text{-pyrone}]$ analogous to the β -dimethylbenzodi- $[\alpha\text{-pyrone}]$ of Hantzsch and Zürcher (*Ber.* 20, 1328(1887)) from orcinol and concd. H_2SO_4 with 2 mols. $\text{AcCH}_2\text{CO}_2\text{Et}$ at 80° or with an excess of $\text{CO}(\text{CH}_2\text{CO}_2\text{Et})_2$ at room temp. failed; in the 1st case was obtained V, in the 2nd III. C. A. R.

Relations between organic rings and the properties of unsaturation. B. K. MEREJKOWSKY *Bull. soc. chim.* 37, 1174-87(1925).—Carvenone with N_2H_4 formed a pyrazoline which was decompd. by dropping on to solid KOH (and some Pt black) at $210-20^\circ$, instead of the expected thujane, 80% of inactive 3-menthane was formed. The pyrazoline from carvone similarly decompd. at 240° gave a little isolimonene, which was hydrogenated to p -menthane; and an undecompd. portion which at $300-50^\circ$ yielded isolimonene and dipentene. The pyrazoline from cyclopentenone (obtained in poor yield by distn. of Ca dihydromuconate) formed, at 180° , only a little cyclopentene. M. concludes that this decompn., which often leads to 3-membered-ring formation, does not form rings within other rings. B. H. NICOLET

The chemistry of pinene. I. L. KONDAKOV. *Caoutchouc & gutta-percha* 22, 12952 (1925); cf. C. A. 20, 407.—A critical discussion of the derivs. of pinene. Past expts render it probable that in nature nopinene is the source of derivs. of fenchene and of sylvestrene and that α -pinene is the source of derivs. of borneol, of terpineol and of terpinol. C. C. DAVIS

Constitution of naphthalene and its derivatives. RUDOLF LESSER, ERICH KRANZPUHL AND GEORG GAD. *Ber.* 58B, 2109-24(1925).—The authors undertook to throw light on the question whether C_{10}H_8 has the sym. (I) or the unsym. (II) structure by detg. with certainty the position of the double bonds in 1 of its derivs. and for this purpose they chose the yellow 2,3-hydroxynaphthoic acid (III) which Möhlau (*Ber.* 28, 3100 (1895)) considers to be 1,2-dihydro-2-keto-3-naphthoic acid and the corresponding NH_2 compd., likewise yellow, to be the 2-ketimido deriv. According to him, replacement of the H in the HO group attached to the nucleus or in the 2 salt-forming groups destroys the quinonoid bond and leads to colorless compds. while he explains the soly. of the Me ester (IV) of III in alkalis with yellow color by assigning the structure V to its Na salt. That this is wrong L., K. and G. have shown by prepg. in pure state a whole series of yellow salts not only of IV but also of the Me ester of 1-bromo-2,3-hydroxynaphthoic acid (VI), which proved to be quite stable; this could not be true if the Br and metal were on the same C atom. On the other hand, they confirmed his conclusion that replacement of the H of the HO group on the nucleus or in the 2 salt-forming groups by any other group yields colorless substances without exception. Thus, the Ac (VII), Bz, MeO_2CO and Me derivs. of III are colorless. When the chlorides of VII and the corresponding 1-Br deriv. are treated with NH_3 there are obtained isomeric colorless O-Ac and yellowish N-Ac derivs. of the amides of III and VI. On the other hand, while there are absolutely colorless derivs. of III with a free HO group (such as the anilide and N-methylanilide), the salts of these and all other derivs. with a free HO group are always yellow. The yellow color of the salts can be explained only on the basis of a quinonoid union, and since such a union between C atoms 1 and 2 (formula I) is excluded, it can be only between C atoms 2 and 3 (formula II) and the structure which seems best to fit the facts is one (VIII) or (IX) analogous to that suggested by Anschütz (C. A. 19, 1416) for the yellow salts of the N-acylsalicylamides. In any case, the facts above establish that in III and many of its derivs. there is a double bond between C

atoms 2 and 3 (formula II). The bearing of this conclusion on some hitherto apparently puzzling observations made on $C_{10}H_8$ derivs. is discussed. The data at hand are not sufficient to permit of detg. with certainty whether all $C_{10}H_8$ derivs. have the asym. structure II: L., K. and G. believe that it is true of all derivs. substituted in only 1 nucleus, while Weinberg's arguments for the sym. structure (I), which, however, are all based on the behavior of derivs. sym. substituted in both nuclei (C. A. 16, 1090), are quite convincing. An attempt was made to obtain direct proof of the sym. position of the double bonds in $2,7-C_{10}H_6(OH)_2$ by introducing 2 different acyl radicals in inverse order (e. g., in 1 case Ac first and then Bz, in the order Bz first and then Ac); in all cases (Ph_2NCO was also 1 of the acyl radicals used), the products proved to be identical, independently of the order of acylation. III, purified through the Me ester (m. $75-6^\circ$; all m. ps. are cor.), m. $222-3^\circ$ and is distinctly yellow; its chloride m. $95-6^\circ$ (Meyer, *Monatsh.* 22, 791(1901), gives 192°), and whether the yellow color is peculiar to it or is due to an impurity could not be detd., as it easily decomps. on recrystn. from benzene. The amide, yellow, m. $217-8^\circ$ (given as $185-8^\circ$ in the literature); yield, 12 g. from 20 g. chloride in C_6H_6 with dry NH_3 . Acetate (VII), obtained almost quant. from the acid boiled a short time in 1.5–2.0 parts Ac_2O with 1 drop concd. H_2SO_4 , m. $184-6^\circ$ (Anschütz, C. A. 3, 2979, gives $176-7^\circ$). Benzolate, m. $208-9^\circ$. 3-Acetoxy-2-naphthamide (X) (6.3 g. from 11.5 g. VII boiled in C_6H_6 with $SOCl_2$ until dissolved, dild. with C_6H_6 and satd. in ice with dry NH_3 , the product being crystd. from Me_2CO), needles, becomes yellowish about 160° , m. $180-90^\circ$ (quite sharply at 185° if plunged into a bath at 180°); the Me_2CO mother liquors yield *N*-acetyl-3-hydroxy-2-naphthamide, faintly yellowish tables, m. $203-5^\circ$. The *O*- partially isomerizes into the *N*-deriv. on slow heating or recrystn. from alc., completely on refluxing 1 hr. in $AcOH$. The amide of III with $AcCl$ in C_6H_5N gives only the *O*-acetate. Both isomers give with Ac_2O the same *O,N*-di-1-*c* deriv., m. $159-60^\circ$. 1-Bromo-2,3-acetoxynaphthoic acid, m. 183° ; with $SOCl_2$ and then NH_3 it yields only 1-bromo-2,3-acetoxynaphthamide, needles, m. $204-6^\circ$, gradually becoming more and more yellow from about 180° up, completely rearranges on heating at 206° or refluxing in $AcOH$ into the *N*-Ac isomer, yellow needles, m. $204-6^\circ$. Amide of VI, from the *O*-acetate and 2 mols. KOH in cold $MeOH$, yellow, m. $258-9^\circ$. 2,3-Acetoxynaphthonitrile (2.1 g. from 3 g. X refluxed in $SOCl_2$), m. 118° , also obtained by treating with cold Ac_2O the K salt of the nitrile of III which cannot be prepd. directly from the amide (in C_6H_6 there is no reaction with $SOCl_2$ and without a solvent there is formed a red, very unstable substance, probably an addn. compd.) but is obtained in 1.2 g. yield from 2 g. of the acetate with KOH in cold $MeOH$; it seps. in not quite colorless rodlets, m. $188-9^\circ$, converted back into the acetate by $AcCl$ in $CHCl_3-C_6H_6N$ and into the amide by cold concd. H_2SO_4 . Me 2,3-methoxynaphthoate (41 g. from 60 g. of the Me ester of III with KOH and Me_2SO_4 in $MeOH$), m. $63-5^\circ$ (given in the literature as $45-9^\circ$), b_{11} $197-8^\circ$; free acid, entirely colorless, m. $134-5^\circ$, reacts with neither $FeCl_3$

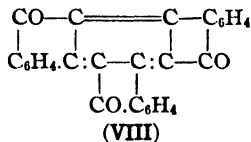

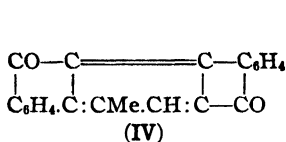

nor diazobenzenesulfonic acid (the slight yellow color observed by v. Auwers and Frühling (C. A. 15, 2085) was due to the presence of traces of III which cannot be removed by repeated crystn. or by reduction with Zn dust or $SnCl_2$, but only by treating in Na_2CO_3 with diazobenzenesulfonic acid as long as a red color is produced, letting stand, pptg. with HCl and extg. the MeO acid with C_6H_6); amide, m. $172-3^\circ$; nitrile, m. $132-3^\circ$. Me ester of VI (45 g. from 40 g. of the ester of III in $AcOH$ suspension with Br), faintly yellow, m. 115° . Salts of the Me ester of III; K, Na, Rb, Cd, Cu (too sol for isolation), Ag (yellow ppt. completely decomp. in a few sec.). K, Na, Rb and Cd salts of the Me ester of VI. K salt of the amide of VI. K and Ag salts of the nitrile of III, stable in H_2O ; the Ag salt with MeI gives 2,3-methoxynaphthonitrile, m. $132-3^\circ$. 2,3-Hydroxynaphthyl Ph ketone (1.5 g. from 10 g. of the chloride of VII with $AlCl_3$ in C_6H_6), orange-yellow, m. $161-2^\circ$; K salt, orange-red, dissociated by H_2O . *N*-Methylanilide of III (prepd. according to Ger. pat. 264,527), m. $192-3^\circ$ (Rosenberg, Ber. 25,

3625(1892), gives 150°, dissolves in alkalis with intense yellow color. **2,7-Dihydroxy-naphthalene derivs.:** *Acetate*, m. 171–2°, insol. in cold dil. NaOH but hydrolyzed on warming (even in H₂O alone), gives no color with FeCl₃, gives only 2,7-C₁₀H₆(OMe)₂ with Me₂SO₄; *benzoate*, m. 199°, insol. in KOH even on addn. of alc., gives no color with FeCl₃, cannot be methylated with Me₂SO₄, MeI or CH₂N₂; *acetate benzoate*, m. 136–7°; *benzoate diphenylcarbamate*, m. 179°; *diphenylcarbamate* (5.3 g. from 8 g. C₁₀H₆(OH)₂ and Ph₂NCOCI in Me₂CO refluxed with aq. KOH), m. 261° (at the same time is formed a little of the *bisdiphenylcarbamate*, m. 176°); *benzyl ether*, m. 151–2°, gives no color with FeCl₃; *dibenzyl ether*, m. 141°. C. A. R.

Spirans. XII. Preparation of [benzo-Δ⁶-suberen-1-one]-2,2'-spiran. HERMANN LEUCHS AND PAUL SANDER. *Ber.* 58B, 2200–2(1925); cf. C. A. 19, 61.—PhCH₂CH₂·CH₂OPh, b₁₄ 180–5°, solidifies –15° to fine needles which again liquefy 10–5°, is obtained from PhOCH₂CH₂Br refluxed 3 days in xylene with 1.5 mols. PhCH₂MgCl, 22 g. with 30% HBr in AcOH at 100° in a sealed tube yields 16 g. Ph(CH₂)₃Br, b₁₄ 115°; 10 g. of this boiled 6 hrs. with 1.15 g. Na in abs. alc. and 16 g. CH₂(CO₂Et)₂, gives 10.8 g. Ph(CH₂)₃CH(CO₂Et)₂, b₁₃ 190–2°, 10.8 g. of which in Et₂O dissolves 1.03 g. Na and on boiling in PhMe with 9.5 g. Ph(CH₂)₃Br yields 9.5 g. *di-Et di-[γ-phen-propyl]malonate*, b₁₃ 262°, m. 56–7°; 7.92 g. boiled 2 hrs. in 50 cc. alc. with 5.33 cc. 7.5 N KOH, evapd. to dryness, treated with NaHCO₃ and extd. with Et₂O, the unsapon ester being put through the same process once more, gives 2.2 g. of the free *acid*, m. 160–4° (decompn.), insol. in hot ligroin, and 2.4 g. of the *mono-Et ester*, sol. in ligroin, m. 86–7°, loses CO₂ 160°, sol. in KHCO₃ but soon sepg. as the K salt. The acid (1 g.) converted into the chloride with PCl₅ in CHCl₃ and, after removal of the CHCl₃ and POCl₃ in *vacuo* at 100°, slowly heated to 150° with 0.1 g. FeCl₃ and then quickly distd. in *vacuo* at 300–50°, gives 0.015–0.02 g. *bisbenzo-Δ⁶-suberen-1-one 2,2'-spiran*, CH₂·CH₂·CH₂—C(CH₂·CH₂·CH₂)₂—CO—C₆H₄, yellowish, m. 142–4°. C. A. R.

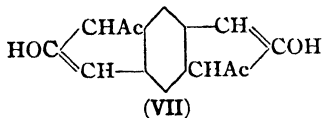

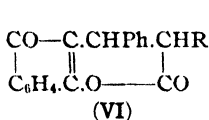

Derivatives of indandione and of biindone. II. Condensation products of aldehydes with biindone. DAN RADULESCU AND VICTOR GEORGESCU. *Bull. soc. chim.* 37, 1187–94(1925); cf. C. A. 19, 3486.—EtCHO and 2 mols. indandione (I) in C₆H₅N at room temp. give propylidenebiindone (II), m. 256–7°, also similarly obtained from biindone (III). When either mixt. is heated, or when II is warmed with KOH, 5-methyl-*o*-trans-fluoracenedione (IV), yellow, m. 289–91°, is formed. The K salt of III with excess H₂CO gives methylenebisbiindone (V), olive, m. 239°; using 2–3 mols. KOH and heating forms, besides V, *indandionylbiindonylmethane*, greenish yellow, m. 210–2°, gives a bordeaux-red color with KOH. V heated in MeOH with a large excess of PhN₂H₁ gives *methylenebis[phenylhydrazinoindandione]*, m. 218–9°. BzH and III in C₆H₅N

to form benzalbiindone (VI), deep garnet needles, m. 235°; in alc. KOH they give *phenylbiindonylmethanol*, m. 238° (decompn.). BzH and 4 mols. I, allowed to stand for days in C₆H₅N, give *phenylindandionylbiindonylmethane*, yellow, m. 303°, also formed from VI and I in hot abs. alc. with a little C₆H₅N. Methylenebisindandione (VII) gives no pyran derivs. with Ac₂O. Heated in air above its m. p., or in PhNO₂, it loses 2H and forms a *methenyl deriv.*, blood-red, m. 203°; Na salt, with NaOEt, also formed when the Na salt of VII is boiled several days in alc. Treated at 0° in AcOH with concd. H₂SO₄, and poured into ice water, VII gives yellow needles (from hot xylene), m. 234°; from AcOH the product, supposed to be *anhydrobisdiindandionylmethane*, seps. with 1 mol. AcOH (not lost in *vacuo* at 114°), m. 180–1°, gives an intense blue-violet color with KOH. 5.5 g. III and 3 g. I in 30 g. C₆H₅N ppt. on long standing *truxene quinone* (VIII), sol. only in hot PhNO₂, yellow, m. > 300°. B. H. NICOLET

Addition characteristics of heterogeneous conjugated systems. MIRCEA IONESCU. *Bull. soc. chim.* 37, 913–6(1925).—2-Benzalindandione (I) condenses with CH₂(CO₂Et)₂ in abs. alc. (C₆H₅N present) to give Et β-indandionyl-β-phenyl-α-carbethoxypropionate (II), m. 108°; using NaOEt, they give the *acid ester* (III), m. 112°, which hydrolyzes to the *acid* (IV), m. 169° (decompn.). IV loses CO₂ to give β-indandionyl-β-phenylpropionic acid (V), m. 173°, colorless, but becomes orange with alkalis. II or III, on heating or with cold concd. H₂SO₄, gave a yellow *lactone* (VI, R = CO₂Et), m. 106°. Heating

IV or treating V with cold H_2SO_4 gave a lactone (VI, $\text{R} = \text{H}$), m. 154° . $\text{H}_2\text{C}_6\text{H}_5$ (VII) and I, with NaOEt , formed γ -[α -indandionylbenzyl]acetylacelone, m. 111° ; this heated under pressure with HCl in AcOH gave 1-phenyl-3-hydroxyfluorenone, yellow, m. 266° ,

and its dihydro deriv., m. 200° . Quinone and VII, with NaOH , formed diacetyldihydroxy-indacene (VIII), green, m. above 300° , and gives an intense violet color with alkalis.

B. H. NICOLET

The nature of melanogen. PIETRO SACCARDI. *Atti accad. Lincei* [6] 2, 346-9 (1925).—The melanogen (I) of the urine is an extremely labile compd. Melanotic urine may be cleared with $\text{Pb}(\text{OAc})_2$ without changing I in it. I may be extd. from acidified urine with Et_2O or AmOH . The Et_2O was evapd. The ext. was taken up in a few drops of HCl . On adding $m\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ in EtOH and evapg. an intense violet color was obtained. Melanotic urine reacts with Ehrlich's diazo reagent and so S. used this to fix I from the Et_2O exts. of urine from rabbits injected with pyrrole. The complex was dissolved in 96% EtOH and evapd. The residue was dissolved in cold NaOH and treated with CO_2 . A red-brown compd. sol. in EtOH was pptd., m. 113° , gives a Bz deriv. easily. This compd. is not the bisdiazopyrrole of Fischer and Hepp. It was concluded that pyrrole does not pass through the organism unchanged and that the azo deriv. isolated is derived from a hydroxylated polymer of pyrrole which constitutes melanogen. Analogously C_6H_6 , indole and C_{10}H_8 when injected are excreted in the hydroxylated forms. The oxidation of pyrrole to I is not due to ferments in the urine. These preliminary results are briefly discussed in relation to the views of other workers.

E. J. WITZEMANN

The preparation of N-methylpyrrolidine by catalytic hydrogenation of N-methylpyrrole. J. P. WIBAUT. *Rec. trav. chim.* 44, 1101-5 (1925).—W. reviews the older results on the reduction of pyrrole derivs. to pyrroline and pyrrolidine derivs. None of these methods is satisfactory and so the catalytic method with Pt black + H_2 in AcOH was used (Willstätter, *C. A.* 6, 2613; Hess, *C. A.* 8, 127, 934; 16, 1250; Adams, *C. A.* 17, 3489). 8.1 g. N-methylpyrrole in 40 cc. glacial AcOH + 0.500 g. Pt oxide (Adams, *l. c.*) in H atm. (with 20 cm. H_2O positive pressure) were placed on a shaking machine so that it could be warmed electrically. The brown oxide was reduced to black Pt black and 4.5 l. H_2 was absorbed (calcd. 4.48 l.). The mixt. was dild. with H_2O , the Pt was filtered off, the soln. was alkalinized with strong KOH and distd., a portion of the distillate acidified with HCl pptd. the N-methylpyrrolidine chloroaurate, m. $216-7^\circ$ (Ciamician, Piccinini, *Ber.* 30, 1789 (1897)). The main portion was satd. with K_2CO_3 and extd. 3 times with Et_2O . The Et_2O was evapd. and the residue was treated with picric acid which pptd. N-methylpyrrolidine picrate (I), m. 221° (Löffler, Freytag, *C. A.* 4, 174). N-Methylpyrrolidine (II) is easily volatile with Et_2O vapors and additional I was pptd. on adding picric acid in Et_2O . A 75% yield of II was obtained. I was decompd. with HCl ; the HCl salt was decompd. with KOH and pure I, b. $78-80^\circ$, obtained from this.

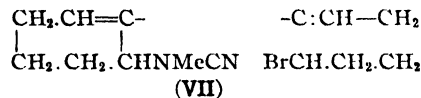

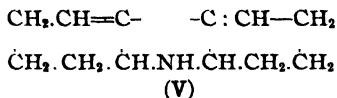

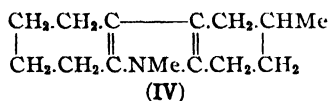

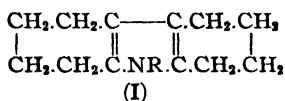

E. J. WITZEMANN

Preparation of indole from ω -o-dinitrostyrene. T. VAN DER LEE. *Rec. trav. chim.* 44, 1089-92 (1925) (In English).— ω -o-Dinitrostyrene (I) was prepd. by nitrating o-nitrocinnamic acid with abs. HNO_3 (v. d. L., *Diss. Leiden* 1925, 37). To 0.7 g. I in 75 cc. 30% AcOH , 1.5 g. Fe powder was added and the mixt. was warmed to 90° . Na_2CO_3 was added to alkalinity and the mixt. was then distd. with steam. The distillate was tested qual. for indole (II) and a 9.4% yield was obtained according to Moraczewski's method (*C. A.* 2, 2578). I reduced with Zn dust + AcOH gave 11% of II. Some II was also obtained on reducing I in Et_2O with Al-Hg. Nenitzescu (*C. A.* 19, 2666) has just published the same method of prep. II and Weerman (*C. A.* 4, 1483; 8, 64), used a somewhat similar method. The reaction mechanism is thought to be as follows: $\text{o-O}_2\text{NC}_6\text{H}_4\text{CH}:\text{CHNO}_2 \rightarrow \text{H}_2\text{NC}_6\text{H}_4\text{CH}:\text{CHNH}_2 \rightarrow \text{H}_2\text{NC}_6\text{H}_4\text{CH}:\text{CHOH} \rightarrow \text{H}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CHO} \rightarrow \text{II}$.

E. J. WITZEMANN

Hydrogenated carbazoles. JULIUS V. BRAUN AND LUDWIG SCHÖRNIG. *Ber.* 58B, 2456-61 (1925).—Perkin and Plant (*C. A.* 18, 3189) have cast doubt on the structure I assigned by v. B. and Ritter to the octahydro compds. they obtained by catalytic hydrogenation under pressure with Ni of N-methyl- and N-ethylcarbazole. The structure I is supported, however, by the extensive study of the hydrogenation of indole

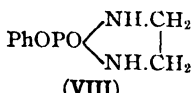

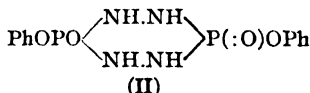

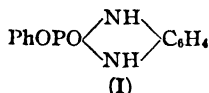

derivs. recently made by v. B. and Bayer (*C. A.* 19, 1862) and v. B. and S. now present what they believe is decisive proof of its correctness. 1,2,3,4-Tetrahydro-6,9-dimethylcarbazole (II), m. 90°, was synthesized from cyclohexanone and *p*-MeC₆H₄NMeNH₂ and the 3,9-Me₂ isomer (III), m. 74°, b₁₂₋₁, somewhat above 190°, from PhNMeNH₂ and *p*-methylcyclohexanone; on hydrogenation both gave the same octahydrodimethylcarbazole (IV), which can be only a pyrrole deriv. and not a compd. with the double bonds unsym. distributed as in the formulas suggested by P. and P. The octahydrocarbazole obtained by P. and P. from cyclohexanonazine with HCl at a high temp. and for which they proposed the structure I, is probably, as already suggested, the sym. compd. V; when its *N*-Me deriv. (VI) is treated with BrCN it does not give MeBr but a quaternary compd. having the empirical compn. 2VI.BrCN; probably 1 mol. VI reacts with the BrCN to form the compd. VII which then adds like a simple alkyl bromide on the tertiary N atom of a 2nd mol. of the VI. IV, m. 36–7°, b₁₂ 165–70°, is very unstable, soon changes in the air into a dark smear, gives with picric acid and HCl in Et₂O first a green color and then an amorphous green ppt., is indifferent towards MeI, giving only a faint brown color. Together with IV is formed the dodecahydro deriv., faintly yellow oil, b₁₂ 130–5°, stable in the air; methiodide, m. 174–5°. 1,2,3,4-Tetrahydro-9-methylcarbazole (VIII), b₁₂ 180°, m. 50–1°, which with Sn and HCl gives the hexahydro deriv. (IX), b₁₅ 144°, b₂₄ 162°, takes up somewhat less than 2 atoms H on catalytic hydrogenation, yielding unchanged VIII, the octahydro deriv., m. 94–5°, and about 30% of P. and P.'s dodecahydro deriv., b₁₂ 125°, whose ethiodide m. 223° (P. and P., 217°) and methiodide, m. 245°. These 2 quaternary salts can conveniently be used to detect the small amts. of dodecahydro derivs. formed when *N*-methyl- and *N*-ethyloctahydrocarbazole are treated with H and Ni in autoclaves with stirring. IX with H and Ni in decalin in an autoclave is at first dehydrogenated, with formation of VIII, which in 1 expt. was isolated in 70% yield. The yield of V can be increased to 30% by simply shaking out the base, after treatment of the azine in decalin with HCl, with HCl instead of removing the decalin with steam. The compd. from VI and BrCN sinters 98°, m. 103°, darkens and gradually evolves a HCN odor in a desiccator.

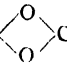

C. A. R.

P-Oxidiazphospholes and experiments with trimethylenedisulfonyl chloride. W. AUTENRIETH AND ERICH BÖLLI. *Ber.* 58B, 2144–50 (1925); cf. *C. A.* 19, 2325.—Compds. of the type OP(OR)Cl₂ condense with bivalent bases to form cyclic compds. contg. both P and N in the ring. Thus OP(OPh)Cl₂ with *o*-C₆H₄(NH₂)₂ gives the compd. I and with N₂H₄.H₂O the compd. II. OP(NHPh)Cl₂ behaves in the same way. The ring in these compds. is stable towards boiling dil. acids but is ruptured by alkalis. That II has not the structure OP(OPh):NNH₂ or the corresponding dimol. form is shown by the fact that it yields no benzal deriv. with BzH: heated for some time with alc. BzH II gives (N:CHPh)₂, PhOH and H₃PO₄. The OP(OR)Cl₂ and OP(NHPh)Cl₂ are quite stable towards cold H₂O; only on boiling are they completely hydrolyzed to H₃PO₄, HCl and ROH or PhNH₂. Unlike the compds. SP(OR)Cl₂, the OP(OR)Cl₂ exchange both Cl atoms for PhO even with dil. aq. alc. solns. of PhOH. Trimethylenebissulfonyl chloride (III) yields the bisulfonamide (IV), -anilide (V) and -phenylhydrazide (VI), but all attempts to convert it into cyclic compds. with N₂H₄.H₂O or *o*-C₆H₄(NH₂)₂ failed; the former always gave VI, the latter the bis[sulfon-*o*-aminoanilide] (VII). OP(OPh)Cl₂ b₁₄ 138–40°. *p*-Toloxylphosphorus oxydichloride, from *p*-cresol and 1 mol. POCl₃ at 140°, b₁₂ 145–50°, liquid of a not unpleasant odor which, when free of dissolved HCl, does not fume in the air, only slowly hydrolyzed by cold H₂O. OP(NHPh)Cl₂, m. 84°, is obtained by heating PhNH₂.HCl and somewhat more than 1 mol. POCl₃, protected with a CaCl₂ tube, on a sand bath until the originally almost solid mixt., which evolves HCl in abundance, has changed to a thick liquid, then adding AlCl₃ and heating only on the H₂O bath. Phenoxy-*P*-oxidihydrobenzodiazphosphonium (I), from OP(OPh)Cl₂ and 2 mols. *o*-C₆H₄(NH₂)₂ at 170° or, in better yield, from the components shaken in C₆H₆ and then refluxed 0.5 hr., m. 185°, mol. wt. in freezing AcOH

194-233. *P,P'*-Diphenoxy-*P,P'*-dioxoletrahydrotetrazadiphosphonium (II), from OP(OPh)Cl₂ in cold H₂O treated dropwise with 2 mols. aq. N₂H₄·H₂O, m. 132°, mol. wt. in freezing AcOH 318-63. *Phenoxy-P-oxoletrahydrodiazaphospholium* (VIII), from OP(OPh)Cl₂ and 3 mols. (CH₃NH₂)₂·H₂O in cold H₂O, m. 196°. *p*-Tolyl homolog of I, m. 158°; of II, m. 168°, mol. wt. in freezing AcOH 423; of IV, m. 204°. *Anilino analog* of I (PhNH instead of PhO), m. 214°; of II (0.3-0.4 g. from 6 g. OP(NHPh)Cl₂, m. 208-10°, mol. wt. in freezing C₁₀H₈ 335-82; of VIII, m. 232°. III, from CH₂(CH₂Br)₂ refluxed in 2 mols. satd. aq. Na₂SO₃ until dissolved (3-4 hrs.), evapd. and heated on the H₂O bath with 2 mols. PCl₅, m. 48°, gives with concd. aq. NH₄OH IV, m. 165°; with 2 mols. N₂H₄·H₂O V, m. 168°; with PhNHNH₂ in boiling C₆H₆ VI, m. 190°, easily sol. in alkalis and reprecipitated by acids; with *o*-C₆H₄(NH₂)₂ in boiling C₆H₆ VII, yellowish, m. 152°, sol. in dil. acids and reprecipitated on cautious neutralization with Na₂CO₃.

C. A. R.

Experiments with thiophosgene. W. AUTENRIETH AND HEINRICH HEFNER. *Ber.* 58B, 2151-6 (1925); cf. preceding abstr.—With *o*-C₆H₄(NH₂)₂, CSCL₂ readily yields the cyclic compd. SC(NH)₂C₆H₄ (I), and with [3,4-(H₂N)₂C₆H₃]₂ it forms SC(NH)₂C₆H₃(NH)₂CS (II), but N₂H₄·H₂O gives only CS(NHNH₂)₂, m. 168°. Neither could a cyclic deriv. be obtained from (CH₂NH₂)₂, although *o*-C₆H₄(OH)₂ in Na₂CO₃ smoothly yielded C₆H₄  CS. As CSCL₂ is itself quite stable towards hot H₂O and cold dil

alkalies it can be used generally for the conversion of phenols into the corresponding Ph esters of CS(OH)₂ and of thiophenols into the esters of CS(SH)₂; on the other hand, no ring formation with bivalent thioalcs. can be effected. With PhNH₂ and other primary aromatic amines CSCL₂ reacts with special ease. OP(OPh)Cl₂ and OP(OH)₂Cl easily yield the corresponding di- and monoanilides with aq. satd. PhNH₂, and with PhOH in dil. aq. NaOH both give PO(OPh)₂. In general, the principle of the Schotten-Baumann benzylation method can be advantageously applied with CSCL₂, OP(OPh)Cl₂ and OP(OH)₂Cl; with primary and probably also with secondary bases, no NaOH need be added. The CSCL₂, m. 73-3.5°, was obtained in 42% yield from CCl₃SCl, which, in turn, was obtained in 60% yield from CS₂ and Cl essentially according to Klason's method (*Ber.* 20, 2376 (1887)). If a cooled mixt. of CSCL₂ and EtOH is at once treated with ice water, SC(OEt)Cl, b. 136°, is obtained in 46% yield. SC(OPh)₂, m. 106°, is obtained almost quantit. from 2 mols. PhOH in a slight excess of dil. NaOH slowly treated with 1 mol. CSCL₂. *Di-β-naphthyl thiocarbonate*, almost white, m. 212° (attempts to prep. the α-isomer in the same way always yielded amorphous, non-homogeneous products). *Pyrocatechyl thiocarbonate* (yield, 25%), faintly pink, m. 154°. SC(SPh)₂ (yield, 90%), yellow-red, m. 95°. *Di-p-tolyl trithiocarbonate*, yellow, m. 115°. CS(NHPh)₂ (yield, 90%) from 4 mols. satd. aq. PhNH₂ treated dropwise with 1 mol. CSCL₂ and shaken vigorously, m. 153-4°, I, colorless or faintly yellow, darkens from 270° on, m. 295-8°. *Diphenylenedithiurea* (II), yellow, amorphous, m. 233°. OP(OH)₂(NHPh)₂, m. 125°. *Diphenyl phosphite monoanilide*, m. 129°. C. A. R.

Some hydroxylated derivatives of 1,2,4-thiazole. H. J. BACKER AND C. H. K. MULDER. *Rec. trav. chim.* 44, 1113-7 (1925).—NH₂CONMeNH₂, prepd. by electro-reduction of NH₂CONMeNO (Backer, *C. A.* 7, 1703), condenses in H₂O with anisic aldehyde, giving MeOCC₆H₄CH:NNMeCONH₂ (I) (Michaelis, Hadanck, *C. A.* 3, 172), m. 192°. This in EtOH with FeCl₃ in the sealed tube for 1 hr. at 110-20°, gave 2-methyl-5-*p*-methoxyphenyl-3-hydroxy-1,2,4-triazole (II), m. 223.5°. I condensed with piperonal gave piperonal-2-methylsemicarbazone, m. 226°, which oxidized as with II gave 2-methyl-5-[methylenedioxyphenyl]-3-hydroxy-1,2,4-triazole (III), m. 273°. II suspended in AcOH treated with N₂O₅ gas gave unchanged II. When II was heated for a moment in HNO₃ + H₂SO₄ and then poured on to ice it gave 2-methyl-5-*p*-nitrophenyl-3-hydroxy-1,2,4-triazole (IV), of which the Na, K and Ag salts were prepd. IV with K₂Cr₂O₇ + H₂SO₄ gave *p*-O₂NC₆H₄CO₂H, m. 238°. PhCH:NNPhCONH₂ (Busch, *Ber.* 36, 1357 (1903)) oxidized as above in EtOH with FeCl₃ gave 2,5-diphenyl-3-hydroxy-1,2,4-triazole, m. 234.5°. NH₂NHCONHPh with BzH gave benzylidene-3-phenylsemicarbazone, m. 177°, which when oxidized gave 4,5-diphenyl-3-hydroxy-1,2,4-triazole, m. 260-1°.

E. J. WITZEMANN

A new synthesis of ricinine. IV. ERNST SPÄTH AND GÖRG KOLLER. *Ber.* 58B,

2124-30(1925); cf. *C. A.* **18**, 1500.—The present synthesis of ricinine (**I**) confirms the structure $\text{MeC}:\text{CH}:\text{C}(\text{OH}):\text{C}(\text{CO}_2\text{Et})\text{C}(\text{OH})\text{:N}$ for the ester (**II**) obtained by Knöven-

agel and Fries by condensing $\text{CH}_2(\text{CO}_2\text{Et})_2$ and $\text{MeC}(\text{NH}_2):\text{CHCO}_2\text{Et}$ with NaOEt (*Ber.* **31**, 768(1898)). From 0.5 g. **II** with CH_3N_3 is obtained 0.4 g. of an oil giving on sapon. 0.1 g. with boiling aq. alc. NaOH 0.1 g. nearly pure *2,4-ametenoxy-6-methylpyridine-3-carboxylic acid*, m. 174–6° (gas evolution); found, 29.54% MeO . *6-Methyl-2,4-dihydroxypyridine-3-carboxamide*, from **II** with NH_3 in abs. alc. at 130°. m. 280–1° (decompn.); 9 g. with POCl_3 at 100° yields 2.5 g. *6-methyl-2,4-dichloro-3-cyanopyridine*, m. 101–2°, 4 g. of which with BzH and ZnCl_2 in an evacuated bomb at 125° gives 2.5 g. *6-styryl-2,4-dichloro-3-cyanopyridine* (**III**), yellow, m. 168–9°; the operations should be carried out in the dark as on illumination **III** changes into a colorless dimer, m. 213–4.5°. *2,4-Dichloro-3-cyanopyridine-6-carboxylic acid* (0.622 g. from 1 g. **III** with KMnO_4 in Me_2CO), m. 180°, decamps. 183°; this, refluxed in MeOH with NaOMe gives *2,4-dimethoxy-3-cyanopyridine-6-carboxylic acid*, m. 205–6°, 0.05 g. of which, cautiously heated over a free flame or in a bath at 260°, loses CO_2 and yields 0.0089 g. *2,4,3-C}_6\text{H}_7\text{N}(\text{OMe})_2\text{CN}, m. 145–6°; this last compd. was converted into **I** as in the earlier synthesis.*

C. A. R.

Color and molecular geometry. IV. Explanation of the colors of the cyanine dyes.

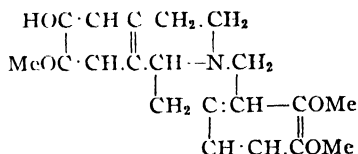

JAMES MOIR. *J. Chem. Soc.* **127**, 2338–43(1925).—The principle that the height of color depends chiefly on the distance between 2 positive centers in the mol. (cf. *C. A.* **19**, 2595) is applicable to all classes of colored compds. In many dyes, however, the mol. contains extensive inactive parts, lying outside the 2 positive centers, which produce a "loading" effect on the color and raise the position of the absorption band 0.5–10.0%. The cyanines, isocyanines ψ -isocyanines, azocyanines and carbocyanines belong to this class and to explain their colors the effect of the "load" had to be quant. detd. To this end several parent substances were studied. There is a minute difference between the colors of ψ -isocyanine salts and of activated di-2-quinolylmethane (cf. Scheibe and Rossner, *C. A.* **15**, 3110), the observations showing a Mc color-factor of 1.005. Similarly the color-factor of activated diquinolylmethane and activated dipyridylmethane is 1.105, a value much like the naphthol/phenol color-factor, indicating that the extra "loading" with part of a C_6H_5 ring has the same effect in each class. All the cyanines have 2 bands close together and the ratio of the adsorption-center wave lengths for the 2 bands of each compd. is almost always 1.065. The change of linking from *ortho* to *para*, i. e., from 2' (or ψ -iso) to 2:4' (or iso) and from iso to ordinary (2:4' to 4:4'), also involves the factor 1.065. These factors, therefore, cancel one another in certain cases, the lower band of a 4:4'-cyanine being in the same position as the higher band of the corresponding 2:4'-cyanine and the lower band of the latter being in the same position as the higher band of the corresponding 2,2'-cyanine. Using these principles, calcn. of the distance between the position centers is shown in detail for di-2-pyridylmethane. The factor 1.065 for calcg. the positions of the bands of cyanines from isocyanines and of isocyanines from ψ -isocyanines also holds true in the carbocyanine series. The concept of 2 positive centers in conjunction with that of comparative mol. rigidity is probably capable of explaining all color phenomena.

C. C. DAVIS

Action of phenyl isocyanate on 2,5-diketopiperazines. MAX LÜDKE. *Z. physiol. Chem.* **150**, 215–9(1925).—Peptides and diketopiperazines behave differently toward PhNCO . The primary amino group of peptides reacts with formation of a substituted urea while the secondary group forms a hydantoin. With diketopiperazines, on the other hand, both secondary amino groups add PhNCO with formation of a phenylurea grouping. By using an excess of PhNCO (3–5 mols.) and a temp. of 170° a yield of 94% may be obtained. The product is purified by washing with Et_2O , boiling with H_2O or EtOH and recrystg. from AmOH . *2,5-Diketopiperazine-1,4-di[phenyl isocyanate]*, decamps. 270°, was prepd. in 67% yield from glycine anhydride and PhNCO ; *3-methyl-2,5-diketopiperazine-1,4-di[phenyl isocyanate]*, m. 158–9°, in 94% yield from glycylalanine anhydride, and *3-benzyl-2,5-diketopiperazine-1,4-di[phenyl isocyanate]*, m. 154° (decompn.), in 93% yield from phenylalanylglycine anhydride. None of these gave the picric acid reaction.

A. W. DOX

Corydalis alkaloids. V. Constitution of corypalmine. ERNST SPÄTH AND ERICH MOSERTIG. *Ber.* **58B**, 2133–5(1925); cf. *C. A.* **19**, 2959.—The position of the HO group in corypalmine (**I**) has now been established. The **I** (0.2 g. from 5 kg. dry buds of *Corydalis cava*), m. 235–6°; 0.093 g. with $\text{EtN}(\text{NO})\text{CO}_2\text{Et}$ and NaOEt in alc. gives 0.079 g. of the amorphous Et ether which in dil. H_2SO_4 treated with Na_2CO_3 to permanent turbidity and immediately oxidized with KMnO_4 yields 7-methoxy-6-ethoxy-1-keto-1,2,3,4-tetrahydroisoquinoline, m. 173–5°. **I** therefore has the structure

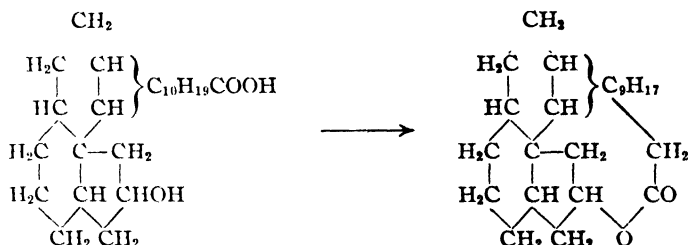

Tetrahydrojatrorrhizine (II) has the same struc-

ture, as will be shown in a paper by S. and Duschinsky to appear soon in the *Ber.* I is, therefore, the dextro-form of II. C. A. R.

Calycanthine. ERNST SPATH AND WILHELM STROH *Ber.* 58B, 2131-2(1925).—The formula $\text{C}_{22}\text{H}_{28}\text{N}_2$ assigned by Gordin (*C. A.* 6, 354) to calycanthine (I) should be doubled, I m. 245° (evacuated tubes), mol. wt. in freezing camphor 331, in boiling C_6H_6 351, in the Bleier and Kohn app. at 340° (boiling phenanthrene) in H under 12 mm. 310 (calcd. for $\text{C}_{22}\text{H}_{28}\text{N}_4$, 318). The HI salt contains 41.78-42.29% I; calcd. for $\text{C}_{22}\text{H}_{28}\text{N}_4 \cdot 2\text{HI}$, 42.02. The active H (Zerevitinov method) in I is 0.44%; calcd. for $\text{C}_{22}\text{H}_{28}\text{N}_2 \cdot (\text{NH})_2$, 0.57. I (0.1222 g. in 10.748 cc. abs. alc.) shows $[\alpha]_D^{18}$ 684.3° . From I heated 10 hrs. at 100° with MeI in an evacuated tube, the process being repeated several times, is obtained a *compd.* m. $261-2^\circ$, contg. 38.97% I; calcd. for $\text{C}_{22}\text{H}_{26}\text{N}_4\text{Me}_2 \cdot 2\text{MeI}$, 38.47; heated a long time at 140° it perceptibly loses MeI. C. A. R.

The bile acids. XXIV. The process of dehydration with formation of neutral substances. HEINRICH WIELAND AND OTTO SCHLICHTING. *Z. physiol. Chem.* 150, 267-75 (1925), cf. *C. A.* 19, 1854.—Vacuum distn. of desoxycholic acid gives in addn. to cholanenic acid an unsatd. isomeric lactone which may be hydrogenated to a satd. lactone, $\text{C}_{27}\text{H}_{48}\text{O}_3$. Hydrolysis with KOH converts the latter into *isolithocholic acid*, $\text{C}_{24}\text{H}_{40}\text{O}_3$, m. $90-5^\circ$ (I), which on oxidation with CrO_3 loses 2H to form the known 7-ketocholic acid. *Me ester* of I, m. $119-20^\circ$; *Et ester*, m. 136° . At 220° I loses H_2O and reverts to the lactone without alteration of the ring structure. The lactone then b. $270-5^\circ$ and solidifies to a vitreous mass. The ring closure is believed to occur as follows:

Similar lactone formation occurs with cholic acid and with pyrodesoxybiliaric acid. Thermal decompn. of 7-ketocholic acid at $320-30^\circ$ gives 50% of a hydrocarbon $\text{C}_{23}\text{H}_{36}$, m. 117° . A. W. DOX

The action of phenylhydrazine and hydrazine on fats and fatty acids (VAN ALPHEN) 27. "Glykose" or "Glucose," "Glykosid" or "Glucosid" (DEUSSEN, *et al.*) 2. Dehydrogenation of methanol and formaldehyde with Cu as catalyst (GHOSH, CHAKRAVARTY) 2. Catalytic formation of methane from CO and H (CHAKRAVARTY, GHOSH) 2. Molecular combinations (MARTINET, BORNAND) 2. Biochemical study of phycoerythrin and phycocyanine (KITASATO) 11A. Dissociation constants of organic molecular compounds (HALBAN, ZIMPELMANN) 2. BRUNN, J. VON: *Lehrbuch der organischen Chemie.* Leipzig: S. Hirzel. 508 pp. M. 24. Reviewed in *Chem. News* 131, 302(1925).

Sulfurizing organic compounds. F. W. ATACK. U. S. 1,571,181, Feb. 2. Indophenols or other material to be sulfurized is heated with S and Na sulfide or other sulfurizing agent in the presence of BuOH or other inert solvent having a b. p. about the same as that of normal BuOH so that the sulfurization is effected at about this temp.

Nitration of organic compounds. J. B. MENKE. Brit. 235,698, May 23, 1924. o-Nitroacetanilide is made by treating aniline with Cu nitrate and Ac_2O , pouring into

H₂O, triturating the pptd. mass with H₂O and recrystg. from dil. alc. Among the other org. compds. which may be nitrated with Cu nitrate and Ac₂O, glacial HOAc or acetyl halide are: acetoacetic ester, malonic ester, isosuccinic ester, glycerol or other polyhydric alcs., phenol (with which ferric nitrate also may be used), dimethylaniline, diphenylamine, toluene, benzoic acid and C₁₀H₈. Nitrates of Ce, Mn, Zn, Ni and Co may also be used and the nitrations are generally carried out at temps. below 60°. Nitrates of the alk. earths and alkali metals have a relatively feeble action.

Halogenated alcohols. FARBENFABRIKEN VORM. F. BAYER & CO. Brit. 235,584, June 12, 1924. Halogenated alcs. are produced from halogenated aldehydes by treating them in an alc. soln. with an alcoholate or halogenated alcoholate of Al or with Al alcoholate and AlCl₃; e. g., an alc. soln. of chloral or butylchloral is heated to the b. p. with Al ethylate while H or N is continuously passed through, the alc. is distd. off and dil. H₂SO₄ added, after which trichloroethyl alc. or trichlorobutyl alc. may be obtained by steam distn. Bromal and monochlorocrotonaldehyde may be similarly treated.

Chlorohydrins. CARBIDE AND CARBON CHEMICALS CORPORATION. Brit. 235,044, Aug. 13, 1924. Chlorohydrin solns. in concd. form are obtained by introducing caustic alkali and Cl into a weak chlorohydrin soln. and then passing a gaseous olefin in to combine with the HClO formed. An app. is described.

Carbocyclic ketones and dicarboxylic acids. M. NAEF ET CIE. Brit. 235,540, June 16, 1924. Carbocyclic ketones with more than 9 ring members are prepd. by treating dicarboxylic acids having more than 10 C atoms or their salts, by ketone prepn methods, preferably by employing the Th or Ce salts. E. g., the Th salt of tetradecane-1,14-dicarboxylic acid is heated to above 400°, preferably *in vacuo* and with the addn of Cu or Fe turnings or other good conductor of heat and the cyclopentadecanone produced is obtained from the distillate by fractionally distg. and then forming the semicarbazone. Manuf. of cyclic ketones from cyclodecanone to cyclooctodecanone is described. From the mother liquor of the semicarbazone a mixt. of semicarbazones yielding mixed ketones may be obtained. Cyclopentadecanone may also be obtained by heating tetradecane-1,14-dicarboxylic acid alone or with Th oxide or Ce or Ac₂O or by passing the vaporized acid over Th oxide, or by gradually heating its anhydride alone or with Th oxide. The cyclic ketones on oxidation with chromic acid give a dicarboxylic acid, e. g., by the oxidation of cyclodecanone, octane-1,8-dicarboxylic acid is formed. The cyclopentadecanone has an odor resembling that of musk or civet.

Arylsulfonic esters. FARBENFABRIKEN VORM. F. BAYER & CO. Brit. 235,598, June 14, 1924. 4-Nitro-1-aminobenzene-2-sulfonic acid phenyl or *o*-methoxyphenyl ester is prepd. by condensing 4-nitro-1-chlorobenzene-2-sulfonylchloride with PhOH or guaiacol in the presence of alkali and heating the product with aq. NH₃ or alc. NH₃ under pressure. 2-Nitro-1-aminobenzene-4-sulfonic acid *p*-cresyl ester is obtained from 2-nitro-1-chlorobenzene-4-sulfonic acid and *p*-cresol. Related nitroaminobenzene-sulfonic esters may be similarly formed.

Organomercury compounds. ABBOTT LABORATORIES. Brit. 236,538, July 2, 1924. 3,5-Diacetoxymercuri-4-nitro-*o*-cresol is prepd. by treating a hot soln. of 4-nitro-*o*-cresol in caustic alkali with an HOAc soln. of Hg(OAc)₂ and neutralizing. The pptd. product is freed from the Hg deriv. of nitroindazole by treating with caustic alkali or NH₄OH, acidifying and washing the ppt. with MeOH and ether. It is a germicide. 4-Nitro-*o*-toluidine is made by nitrating *o*-toluidine in H₂SO₄ at a low temp. and decomposing the sulfate with NaOH. 4-Nitro-*o*-cresol is formed by diazotizing a hot H₂SO₄ soln. of 4-nitro-*o*-toluidine with NaNO₂ and injecting steam into the product, sepg. black tarry oil of nitroindazole, and cooling to effect crystn.

Organoarsenic compounds. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Brit. 235,864, June 18, 1924. Benzaldehydearsonic acid, treated with acetone semicarbazone, yields the semicarbazone of benzaldehydearsonic acid and liberates acetone. *p*-Acetophenonearsonic acid by reaction with acetone hydrazone produces the hydrazone of *p*-acetophenonearsonic acid and free acetone and by reaction with acetone semicarbazone form the corresponding semicarbazone and free acetone. The As compds. thus produced may be used as therapeutic agents.

Metalddehyde. ELEKTROTRIZÄTSWERK LONZA. Brit. 235,867, June 23, 1924. Polymerization of AcH to metalddehyde is catalyzed by compds. such as NH₄Br, hydrazine hydrochloride, pyridine hydrobromide and perborate, halogenated pyridines, urea hydrochloride, diphenylthiourea hydrobromide, the hydrohalides of alkylamines and (CH₃)₃N₄, tetraethylammonium trichloride, quinoline tribromoacetate, anisaldehyde hydrochloride, benzalacetophenone hydrobromide, thiophene and hydroxylamine or nitrilo-sulfonic acid together with a strong inorg. acid.

Olefin oxides. J. N. BURDICK. Brit. 236,379, July 9, 1924. A 10% ethylene

chlorohydrin or propylene chlorohydrin soln. or other chlorohydrin soln. of less than 40% concn. is heated with alkali, *e. g.*, with NaOH at the b. p., and the resulting ethylene oxide or other olefin oxide produced is removed and condensed as formed. Cf. C. A. 19, 657.

Alkyl chlorides. T. GOLDSCHMIDT AKT.-GES. Brit. 235,547, June 10, 1924. Alkyl chlorides, other than EtCl, are obtained by treating gases contg. the lower olefins with HCl in the presence of a catalyst which may be Fe oxide or chloride, preferably at ordinary temp. Any C_2H_4 present is not attacked under these conditions, but chlorides may be produced from C_3H_6 and C_4H_8 in mixed olefinic gases.

Ethyl chloride. CHEMISCHE FABRIKEN VORM. WEILER-TER MEER. Brit. 235,521, June 12, 1924. C_2H_4 is combined with HCl under pressure in the presence of an inert solvent which may be EtCl itself. Gases contg. C_2H_4 may be used and $AlCl_3$ or its double compd. with C_2H_4 is used as a catalyst. A pressure of 60 atm. may be used.

Hexamethylenetetramine. S. KARPEN & BROS. Brit. 235,015, June 24, 1924. Methylene chloride is heated for several hrs. at 80–120° in an autoclave with sufficient aq. NH_3 to give an excess of 300–400% of theoretical proportions. The resulting soln. of $(CH_2)_6N_4$ and NH_4Cl may be evapd. with addn. of NH_3 to prevent hydrolysis, and the $(CH_2)_6N_4$ sepd. by use of a solvent such as $CHCl_3$ or CCl_4 . Or, if the process is conducted to give a satd. soln. of the products, the hot soln. may be cooled to crystallize NH_4Cl and NH_3 then added to ppt. $(CH_2)_6N_4$. Cf. C. A. 20, 768.

FRANK P. UNDERHILL

The bile acids. XXIII. The composition of human and beef bile. The constitution of anthrope-desoxycholic acid. HEINRICH WIELAND AND RICHARD JACOBI. *Z. physiol. Chem.* 148, 232–44 (1925); cf. C. A. 19, 1854.—From the mother liquor remaining after crystn. of the Na salt of anthrope-desoxycholic acid, lithocholic acid was obtained by acidifying and fractional shaking out with Et_2O and 0.2 N NaOH. The amt. obtained was 0.6 g. from 20 l. of human bile. All 3 acids previously isolated from beef bile have now been found in human bile. Anthrope-desoxycholic acid (I) was isolated from beef bile by means of the Ba salt. Ethyl anthrope-dehydro-desoxycholate, m. 133°, was prepd. by oxidation of I and esterification of the dehydro acid. I may be converted into lithocholic acid by prepn. of the semicarbazone, heating this with NaOEt at 180° and acidifying with HCl. Both I and its dehydro acid may be oxidized to anthrope-choloidanic acid (II), $C_{24}H_{36}O_{10}$, m. 213° by means of HNO_3 . By heating II at its m. p. in an atm. of N, 1 mol. of CO_2 is split out and a tetracarboxylic acid, $C_{23}H_{30}O_8$, is formed in 30% yield; hence II contains a malonic acid grouping. Distn. of II in a high vacuum above 300° yields a pyro-anthrope-choloidanic acid, $C_{22}H_{28}O_4$, m. 142°. This is probably a diketocarboxylic acid. The same positions are assigned to the 2 OH groups in I as by Wieland and Jacobi for cheno-desoxycholic acid which is identical with I. A. W. Dox

Depolymerization of proteins and re-synthesis of protein-like substances from the fission products. K. SHIBATA. *Acta Phytochim.* 2, 39–47 (1925).—Carefully dried casein, serum albumin, fibroin, gelatin, or Witte's peptone when heated with glycerol at 180–190° passes into a mixt. of anhydrides of the simple amino acids. Human hair, wool, feathers, tortoise-shell and horn are similarly depolymerized, but they require more glycerol and longer heating. The conversion of amino acid anhydrides into protein-like substances is accomplished by heating with glycerol, *e. g.*, glycyltyrosine anhydride gives a product showing the Millon and xanthoproteic acid reactions. Free amino acids behave similarly, since they are converted into anhydrides under the conditions of the expt. Asparagine yields an amorphous powder giving a colloidal soln. which shows the carbonyl and biuret reactions. Asparagine with tyrosine gives a product showing the Millon test and with cystine a product showing the Pb sulfide test. The action of proteolytic enzymes is discussed. B. C. A.

Biochemical study of phycoerythrin and phycocyanine. Z. KITASATO. *Acta Phytochim.* 2, 75–97 (1925).—Phycoerythrin and phycocyanine are obtained in cryst. form by salting out the aq. ext. of a Bangiaceae, *Porphyra tenera* Kjellm., with $(NH_4)_2SO_4$ and are purified by repeated soln. and salting out followed by dialysis to remove adhering salts. Analysis then gives the following results, for phycoerythrin, C 50.87,

H 7.04, N 15.34, S 1.76, O 24.99% and for phycocyanine, C 50.60, H 6.90, N 15.76, S 1.69, O 24.97%. These substances are decomposed by acids, alkalis and proteolytic enzymes into a protein and a colored substance. The protein from phycoerythrin resembles a globulin in its general properties and that from phycocyanine is very similar. Phycoerythrin on digestion with pepsin gives a reddish violet, water-sol. pigment, $C_{48}H_{120}O_{18}N_{12}$, which on warming with acids gives an amino complex, $C_{18}H_{60}O_6N_4(NH_2)_2$, and a blue pigment sol. in org. solvents, insol. in water and acidic in character, $C_{30}H_{64}O_{12}N_8 \cdot 1.5H_2O$. Phycocyanine on peptic digestion gives directly a protein constituent and the blue pigment, the reddish violet intermediate substance not being formed. It appears, therefore, that the amino compd. det. the difference between phycoerythrin and phycocyanine and with the former gives the more basic character and the resistance to alkali and acids. Spectrographic investigation of phycoerythrin, phycocyanine and their decompn. products confirms these views. B. C. A.

Specific nature of lipases with respect to configuration. R. WILLSTÄTTER. *Sitzb. Akad. München* 1924, 1-2.—Lipase from the pancreas hydrolyzes glycerides 10-20 times as rapidly as that from the liver; the explanation may be that the soaps produced in the process cause a large increase in activity of the former enzyme only. The influence of proteins on these 2 enzymes is also different. The 2 enzymes are proved to be definitely distinct by the observation that the enzyme from pig's liver produces *d*-mandelic acid in hydrolyzing Et *dl*-mandelate, whereas that from the pig's pancreas yields the *l*-stereoisomeric under the same conditions. B. C. A.

Salt formation between creatine and sodium hydroxide. A. HAHN AND H. FASOLD. *Z. Biol.* 82, 473-84(1925).—A satd. aq. soln. of creatine at 10° contains 10.9 g. of creatine per l.; at 12°, the amt. lies between 14.4 and 14.9 g. The amt. dissolved in NaOH increases from 12.72 g. per l. in 0.2 *N* soln. to 23.20 g. in *N* soln. K_a for creatine is 5.2×10^{-15} . Since K_b is 5×10^{-12} (C. A. 15, 867) creatine is about a thousand times stronger as a base than it is as an acid. The hydrolysis of the Na salt of creatine increases with diln., being almost complete in 0.05 *N* to 0.025 *N* soln. The velocity of the conversion of creatine into creatinine by NaOH increases slowly with the concn. of the alkali. B. C. A.

New protein derivatives with a high bromine content. A. J. J. VANDEVELDE. *Bull. acad. roy. med. Belg.* [5], 5, 472-85(1925); cf. C. A. 19, 2502.—A 3% soln. of Br₂ in CCl₄ is shaken with the dry protein, at ordinary temp., for several days or weeks (15 g. of protein with 100 g. of the soln.). In this way a bromocasein is obtained with 35.2% of Br, a bromofibrin with 41.6% Br, a bromoöovoprotein with 37.5%, a bromogluten with 30%, a bromopeptone with 37.5%, a bromotyrosine with 57.3%. Only in the case of tyrosine is HBr formed in a considerable amt.; in all the other cases an addition without a substitution appears to take place; the bromotyrosine is also the only compd. corresponding to a definite formula, viz., $C_9H_{10}O_3Br_3$. The taking up of the large amts. of Br by the proteins is likely to be due to double bonds or to residual valencies of N atoms. The bromoprotein compds. are decomposed by water at ordinary temp., a part of them going into soln., another part remaining insol.; both the sol. and the insol. part contain Br, the amt. of which largely depends on the duration of action of the water. Also the amt. of bromoprotein which remains insol. depends on the time of action. At higher temps. a larger portion of the bromoprotein goes into soln. If NaOH is added to the water acting upon the bromoprotein, the bromocasein, *e. g.*, is dissolved completely, but a larger part of the Br is liberated; the sol. portion contains less Br. Alc. acts similarly to water, decomposing the bromoprotein into a sol. and an insol. portion; in bromocasein the insol. portion contains 14.7% Br. The decompn. with water, alkali and alc. is studied for all the bromoproteins mentioned, under similar conditions of time and temp. and found to vary widely for all of them. These bromoproteins are yellow, have an irritating odor and are very hygroscopic, especially the bromopeptone. Bromotyrosine is without color and odor and is sol. in water without decompn. R. BEUTNER

The influence of hydrogen-ion concentration on the dextrinizing of starch by purified malt diastase. T. CHRZASZCZ, Z. BIDZINSKI AND A. KRAUSE. *Biochem. Z.* 160, 155-71(1925).—No definite optimum p_H was found in the dextrinizing of starch by amylase. The optimum p_H depends on the temp., the diastatic action, the buffers present and the protective action of the starch. A range of p_H 4.4 to 5.4 was optimum at a temp. range of 20° to 75°. The temp. of inactivation is in part detd. by the existing p_H . F. A. CAJOMI

Quinine- and atoxyl-fast lipases in organs of internal secretion. E. HERZFELD AND W. ENGEL. *Biochem. Z.* 160, 172-7(1925).—By observing the effect on the surface tension of tributyrin solns., lipases were demonstrated to be present in the exts. of

pig liver, thymus, ovary, testicle, hypophysis, etc. The lipases were about equally resistant to quinine and atoxyl. F. A. CAJORI

Investigation on blood proteins. II. The action of coagulation-diminishing salts on plasma and serum. H. HUECK. *Biochem. Z.* 160, 183-98(1925); cf. *C. A.* 20, 609.—Na citrate when added to whole blood or plasma affects the readings of the refractometer and viscosimeter. The calcd. protein content of plasma or serum may vary significantly when this calcn. is made from refractometer and viscosity data, depending on the amt. of citrate present. F. A. CAJORI

The physiological behavior of acetoin. I. The behavior of acetoin towards yeast. C. NEUBERG AND M. KOBEL. *Biochem. Z.* 160, 250-5(1925).—Acetoin was added to an actively fermenting yeast and sugar mixt. After some days, when sugar was no longer present, β , λ -butylene glycol was extd. from the mixt. with EtOH and Et₂O and identified as such. F. A. CAJORI

Thiocyanates and cellular respiration. N. TARUGI. *Ann. chim. applicata* 15, 416-26(1925).—It has already been shown (*Gazz. chim. ital.* 32, ii(1902); 34, ii(1904); Venturoli and Pinzi, *C. A.* 5, 849) that thiocyanates form peroxides when oxidized; Fe⁺⁺⁺ give FeHC₃N₃SO₃. When a few drops of concd. HNO₃ were added to a mixt. of a few cc. each of satd. aq. KSCN and Et₂O the reaction became violent, but if kept cold the Et₂O became intense red. After sepn. this Et₂O soln. on standing at room temp. became warm spontaneously owing to decompn. of the red compd. to a pseudothiocyanate (cf. Tarugi, *Intorno alla colorazione rossa che i sali ferrici producono coi solfocianuri*, Istituto chim. farm. Pisa 1907). After filtration of this soln. a violet-red soln. was obtained which was identical to that obtained from Fe⁺⁺⁺ salts and was stable for a few min. Spectroscopic examn. showed a broad band extending from the D to the F line, the spectrum being identical with that of an Et₂O soln. obtained by oxidation of the thiocyanate with HNO₃ or with Fe⁺⁺⁺. The red compds. obtained from Fe⁺⁺⁺ salts and rhodaninic acid (cf. Miolati, *Ann.* 262, 84) and thioglycolic and thiolactic acids (cf. Meyerhof, *C. A.* 18, 2349) are probably also peracids. Acid solns. of the Fe⁺⁺ and Fe⁺⁺⁺ salts of the last two are colorless, but become red when aerated. On standing this red again disappears, owing to oxidation of the thioglycolic or thiolactic acid at the expense of the red compd., with formation of dithioglycolic or dithiolactic acid. This last transformation proceeds to completion. The red compd. is therefore, an *intermediate peracid* formed by a transfer of O by the Fe⁺⁺ salts. On making alk. either the Fe⁺⁺ or Fe⁺⁺⁺ thioglycolate or thiolactate the color becomes amethyst-red because of formation of this peracid, which in turn disappears through formation of the dithioglycolate or dithiolactate. Ferric dithioglycolate or dithiolactate was obtained from the Fe⁺⁺⁺ compds. and ferrous dithioglycolate or dithiolactate from the Fe⁺⁺ compds., which disagrees with the theory of Warburg in which oxidation of Fe⁺⁺ is presupposed (cf. *C. A.* 19, 3277). Cystein likewise forms an *intermediate peracid*, which decomp. rapidly through oxidation of the cystein to cystine. Various references are cited to show that there are Fe⁺⁺ salts of peracids and, therefore, doubt of the existence of this red compd. because of the necessary coexistence of Fe⁺⁺ and peroxidized groups is invalid. As further evidence of the coexistence of Fe⁺⁺ and peracid, Na perbenzoate (cf. Baeyer and Villiger, *Ber.* 33, 858) when mixed at a low temp. with its equiv. of FeSO₄ still gives the reaction of Fe⁺⁺. Likewise solns. of peroxymonophthalic acid and Fe⁺⁺ salts give an amethyst colored soln. which in turn gives, after long standing, the reactions of Fe. Since, as has been shown, the -SCN group has the power of forming intermediate peroxidized compds. with the aid of oxidizing agents such as Fe⁺⁺⁺ salts, it is probable that its presence accelerates every oxidation process and because of the wide diffusion of HS-CN in the animal organism it plays an important role in respiration. Moreover, since this peracid of the -SCN group can be formed in the absence of Fe compds., it is probable that together with Fe compds. it plays a part in cellular respiration. C. C. DAVIS

The oxalacetic acid fermentation. C. NEUBERG AND G. GORR. *Ergebnisse Physiol.* 24, 191-5(1925); cf. *C. A.* 19, 2683.—Oxalacetic acid was decarboxylated to the extent of 70% at room temp. by dry yeast while 93% of the calcd. CH₃CHO was obtained. In the presence of Na₂SO₃, acetaldehyde alone is formed, while in its absence the latter condenses to MeCH(OH)COMe. H. J. DEUEL, JR.

Biology and dielectric constants. E. A. HAFNER. *Ergebnisse Physiol.* 24, 566-87(1925). H. J. DEUEL, JR.

Ultrafiltration and compensation dialysis. A. AUGSBERGER. *Ergebnisse Physiol.* 24, 618-47(1925).—A formula is derived and worked out graphically for the ultrafiltrate (dialyzate and residue). By the use of this and from published data on the ionization in blood serum the following new conclusions are drawn: (1) A part of the

serum sugar is in colloidal soln. (2) The portion of the Ca in colloidal soln. is about 10% higher than previously assumed. (3) Mg is from 20 to 30% colloidal. (4) K yields in acid medium a complex salt with protein but not in neutral or alkaline soln. (5) About 10% of the Na is in colloidal form. It seems promising by the use of this method to det. the ratio of the salts between blood corpuscles and plasma.

H. J. DEUEL, JR.

Recent work on the configurational relationships of biologically important substances. P. A. LEVENE. *Ergebnisse Physiol.* **24**, 663-89(1925); *C. A.* **20**, 577, 579.—A discussion of the configurational relation of hydroxy acids, amino acids, simple sugars and sugar acids established on the basis of van't Hoff's superposition system, the influence of external conditions on configurationally related substances, the effect on optical rotation of change of polarity of one of the groups attached to the asymmetric C atom, and the configurational relationships between 2-aminohexoses and 2-amino-hexonic acids.

H. J. DEUEL, JR.

Invertase. XII. RICHARD WILLSTÄTTER, KARL SCHNEIDER AND IRWIN WENZEL. *Z. physiol. Chem.* **151**, 1-30(1926); cf. *C. A.* **20**, 770.—The method for obtaining a highly active invertase has been still further improved. The more energetic treatment of undild. yeast under suitable conditions leads to a less destructive and more selective liberation of invertase than the milder and more prolonged treatment of dild. yeast. The new preps. of the same degree of activity are much more stable and suffer no loss during the final evapn. and electrodialysis. In the previous preps. a limit of activity was attained beyond which no further purification resulted by adsorption on kaolin or $\text{Al}(\text{OH})_3$. It appears that the enzyme was so firmly bound to its co-adsorbents that the complex behaved like an individual substance. At this stage, however, a fractional pptn. with tannin was found to be effective. The purer invertase preps. give at ordinary temp. no ppt. with tannin, but are pptd. at 0° . Although this treatment does not effect a complete sepn. of enzyme from its impurities, especially tryptophan, it is possible to isolate a purer enzyme from the tannin ppt. and leave a less pure form in the mother liquor. A considerable advance in technic consists in a process of fractional adsorption on an adsorbent developed in the soln. in the presence of the enzyme. When the point is reached where no increase in activity is obtained by the kaolin and $\text{Al}(\text{OH})_3$ treatment, a further purification results by a progressive pptn. of PbHPO_4 . In this way it is possible also to sep. the enzyme from its inactivated form. The 1st portions of ppt. contain only inactivated enzyme. Although a tryptophan complex so frequently remains in the purified enzyme that Euler and Josephson considered it an integral component, it is now shown that this is of no sp. importance so far as enzyme stability is concerned. As a "colloid carrier" it stabilizes the enzyme, but it can be displaced by other peptides which serve the same purpose. Fractional pptn. with PbHPO_4 in the presence of added leucylglycine or leucylglycylglycine diminishes the tryptophan content of the enzyme, whereas without the addn. of peptide no diminution occurs. In 1 instance a tryptophan-free product was obtained. If a sp. protective substance is required to maintain stability, the substance is neither yeast gum nor a peptide contg. tyrosine or tryptophan.

A. W. DOX

The specificity of animal proteases. V. Intestinal erepsin. ERNST WALDSCHMIDT-LEITZ AND ANTON SCHAEFFNER. *Z. physiol. Chem.* **151**, 31-55(1926); cf. *C. A.* **20**, 212.—Intestinal erepsin, when purified from all trace of trypsin by adsorption on $\text{Al}(\text{OH})_3$, is sp. for di- and tripeptides of naturally occurring amino acids and does not hydrolyze peptic peptone, protamine, histone, casein or any other protein. It is identical with pancreatic erepsin in every respect, including specificity, adsorption phenomena and p_{H} optimum. For the detn. of erepsin the most satisfactory method consists in titration of the COOH group liberated from a dipeptide at p_{H} 7.8 (phosphate buffer), adding MeOH to make 85% and using thymolphthalein as indicator. The amt. of enzyme used should be so chosen that the measured reaction const. lies between 0.005 and 0.0005 and the hydrolysis should not exceed 60%. The "erepsin unit" is 1000 times the amt. of enzyme for which a reaction const. of 0.001 is obtained under the conditions prescribed, and the "erepsin value" is the no. of units in 1 g. of material. On account of the low stability of erepsin, purification by pptn. methods is not feasible except in the preliminary pptn. by AcOH. The most stable preps. are glycerol exts. with or without H_2O . At p_{H} 4.7, especially in the presence of EtOH , the enzyme is adsorbed by $\text{Al}(\text{OH})_3$, leaving the trypsin in the mother liquor. Elution is then performed with faintly alk. phosphate soln. This treatment does not increase the enzyme activity but effects a complete sepn. from trypsin. Kaolin also adsorbs erepsin in acid soln. and from the adsorbate the enzyme may be recovered by elution with alk. phosphate, but without increase in activity.

A. W. DOX

An attempt to explain oligodynamic action. J. VOIGT. *Klin. Wochschr.* **4**, 2387-8 (1925).—A globule of Hg was imbedded in aq. gelatin for 14 days. The gelatin was then covered with formalin for 4 weeks. Metallic Hg was pptd. in the gelatin layer, which shows that the original globule of Hg must, to some extent, have passed into soln. in the ionic form.

MILTON HANKE

The influence of ultra-violet light on the acidity of gastric juice. PHILIPP KELLER AND MELITA LOEB. *Klin. Wochschr.* **4**, 2390-2(1925).—The variations in the acidity of the gastric juice from day to day without treatment were fully as great as those obtained after irradiation. Definite conclusions cannot be drawn from the experimental data.

MILTON HANKE

Demonstration of the hypophyseal hormone in the fluid of the human cisterna cerebello-medullaris. JULIUS JÁNOSSY AND BÉLA HORVÁTH. *Klin. Wochschr.* **4**, 2397-8(1925).—The hypophyseal hormone is secreted into the third ventricle. It can be found, regularly, in the fluid of the cisterna cerebello-medullaris.

M. H.

The significance of carotin for the animal organism. F. GOEBEL AND A. STERN. *Klin. Wochschr.* **4**, 2434-5(1925).—Carotin has no effect upon cellular respiration.

MILTON HANKE

The hormone of the parathyroid gland. HANS SCHULTEN. *Klin. Wochschr.* **4**, 2487-8(1925).—Largely a bibliographical review. The exptl. work is a repetition of the work of others. S. concludes that it is possible to ext. a substance from parathyroid glands with HCl, that simulates what is believed to be the *in vivo* action of the gland

MILTON HANKE

Recent advances in science: Biochemistry. R. K. CANNAN. *Science Progress* **20**, 405-8(1926).—Review of recent work on biochem. oxidation and reduction.

JOSEPH S. HEPBURN

The theory of salt craving. N. J. HARRAR. *J. Chem. Education* **2**, 1054-8(1925).—Bunge's theory is refuted. Probable factors in salt craving are the chloride content and potential acidity or basicity of the diet and the comparative water content with its effect on the osmotic pressure of the body fluids.

E. H.

General introduction to a discussion of the hormones. E. M. K. GEILING. *J. Chem. Education* **3**, 41-4(1926).

E. H.

The hydrogen-ion concentration and basicity of egg yolk and egg white. D. J. HEALY AND A. M. PETER. *Am. J. Physiol* **74**, 363-8(1925).—The p_H of the yolk of new-laid eggs is 6.36 (I), that of the white 8.24 (II). I remains practically const. for 3 weeks; II is rapidly altered. A CO_2 atm. does not affect I but distinctly increases II. Both are diminished in the first few days of incubation. II increases later with the development of the chick. The behavior of II toward indicators suggests the presence of $NaHCO_3$ or $KHCO_3$ with excess CO_2 . The phenolphthalein reaction of II is suggested as a test for freshness.

MARY JACOBSEN

Sulfatase. VI. The occurrence and behavior of sulfatase in human organs. L. ROSENFELD. *Biochem. Z.* **157**, 434-7(1925); cf. Neuberg and Simon, *C. A.* **19**, 2674. —Sulfatase is present in various organs. Potassium phenyl sulfate is split from 26.78% by the kidney to 5.83% by the pancreas in 18 days. The activities of the different organs decrease in the order: kidney, brain, liver, duodenum, suprarenals, spleen, lung, muscle, small intestine and pancreas.

W. D. LANGLEY

Physicochemical investigation of uric acid. III. The nature of the hydropic supersaturated uric acid solution. R. STERN. *Biochem. Z.* **159**, 192-8(1925); cf. *C. A.* **19**, 1578, 3496.—In a supersatd. soln. of uric acid, all of the uric acid dissociates to give H ions; this is evidence that the acid does not exist in colloidal form, but rather as a true solution.

W. D. LANGLEY

Influence of bile upon the hydrolysis of albumin by pancreatic juice. L. P. ROSENOW. *Biochem. Z.* **159**, 240-4(1925).—Zymogenous pancreatic ext. was obtained from a dog with a Pavlov fistula, and was activated by intestinal juice from the same animal. The addn. to albumin of either fresh or heated bile with this ext. doubled the rate of digestion, and prolonged the activity of the enzyme, probably by preventing the action of trypsin upon itself.

W. D. LANGLEY

Permeability of lipid mixtures. A. SCHÄFER. *Biochem. Z.* **159**, 250-6(1925).—The distribution coeff. of $Fe(CNS)_3$ between H_2O and Et_2O , C_6H_6 , oil, and mixts. of the same are not const., but depend upon the nature of the oil mixt. and upon the amt. of $Fe(CNS)_3$ used.

W. D. LANGLEY

Metabolism of phosphorus. I. Hexose-phosphatase in human organs and body fluids. F. DEMUTH. *Biochem. Z.* **159**, 415-23(1925).—A phosphatase is found in kidney, nerve, spleen, muscle, pancreas and liver tissues. The optimum p_H for the enzyme is from 6 to 7.3. The same enzyme is apparently present in bile, gastric juice,

milk, urine, cerebrospinal fluid, and blood serum. Its activity in cerebrospinal fluid during meningitis and in serum during rickets and tetany is sub-normal. W. D. L.

Methylglyoxalase. O. MEYERHOF. *Biochem. Z.* 159, 432-43(1925).—The rate of formation of lactic acid from methylglyoxal by glyoxalase is accelerated by tissues and tissue exts. Brain tissue is much more active than muscle or liver and the speed is independent of the presence of O or NaF. Narcotics such as urethan, phenylurethan, thymol and heptyl alc. slow the reaction. Tissue exts. are more active than tissues themselves, and it is shown that there is no ultrafilterable coenzyme present. HCN, in concns. of 2×10^{-6} to 1×10^{-4} M, acts in neutral soln. as a catalyzer of the reaction, but not because of an addn. of HCN to the aldehyde. W. D. LANGLEY

Physiology and chemistry of plant phosphatides. V. GRAFE. *Biochem. Z.* 159, 444-8(1925).—Phosphatides and cerebrosides seem to be the mother substances of vitamins. W. D. LANGLEY

Pringsheim's complement of amylases. K. SJÖBERG. *Biochem. Z.* 159, 468-71 (1925).—S. is able to confirm the finding of Pringsheim that a complement from yeast aids the action of amylase upon starch, but the hydrolysis is increased only about 10 or 20%, instead of being carried to completion. W. D. LANGLEY

The isolation of Schardinger's enzyme from milk. A correction. F. G. HOPKINS AND M. DIXON. *Biochem. Z.* 159, 482-3(1925).—H. and D. believe that their enzyme, prep'd. by pptn. with $(\text{NH}_4)_2\text{SO}_4$ (cf. *C. A.* 19, 303), was purer than that of Sharsky and Michelin, who ppt'd. theirs with $(\text{CH}_3)_2\text{CO}$ (cf. *C. A.* 19, 3277). W. D. LANGLEY

Heat of combustion and elementary analysis of animal fat. F. W. KRZYWANIEK. *Biochem. Z.* 159, 507-9(1925).—To secure an accurate respiratory quotient, the nature of the fat being burned must be considered. The CO_2 production, O consumption and heats of combustion of fats from the horse, sheep, cow, swine and dog are given. W. D. LANGLEY

Effect of metal salts upon the decomposition of hydrogen peroxide by blood. L. BLEYER. *Biochem. Z.* 161, 91-103(1925).—The effects of different salts (27 in all) at various concns. upon the rate of decompn. of H_2O_2 by blood catalase from rabbits are studied. Those salts whose solns. gave acidities outside of the optimum p_{H} ($=6.2$) for catalase were titrated to this point. Most of the salts retard the action of the catalase. The rate of decompn. showed the reaction to be monomolecular. The poisoned enzyme could not be reactivated. W. D. LANGLEY

Chemical composition of insulin. E. GLASER AND G. HALPERN. *Biochem. Z.* 161, 121-7(1925).—A com. insulin, of which the method of purification is not given, was dialyzed to free it of salts and hydrolyzed with HCl. The various forms of N present in the hydrolysate were then det'd. by the method of Van Slyke. The amino acids found to be present were lysine, arginine, histidine and leucine. These were united in peptide linkages. W. D. LANGLEY

Influence of different preparations of quinine upon the enzymic function of organisms. III. Influence of some quinine and urea compounds upon pancreas lipase. I. A. SMORODINTZEV AND V. A. DANILOV. *Biochem. Z.* 161, 178-94(1925); cf. *C. A.* 18, 1156.—An ext. of pancreas is allowed to act upon triacetin in the presence of quinine and urea and mixts. of the same and the amt. of hydrolysis which occurs is measured by titration with alkali. Quinine-HCl in concns. up to 0.05 N increases the rate of hydrolysis, but when urea-HCl is added with the quinine the effect is reversed. W. D. LANGLEY

Effect of different preparations of the quinine group on the enzymic functions of the organism. V. Effect of the concentration of the substrate on the hydrolysis of triacetin by pancreatic lipase. I. A. SMORODINTZEV AND V. A. DANILOV. *Biochem. Z.* 164, 394-400(1925); cf. preceding abstract.—Quinine-HCl accelerates the hydrolytic decompn. of 0.5-1% triacetin by pancreatic lipase. With higher concn. of the triacetin (3-5%) the quinine has no effect at all during the first hrs., but after 3-4 hrs. there is a slowing of the process. The velocity of the hydrolysis of the triacetin by pancreatic lipase both in the presence or absence of quinine and independently of the substrate concn. follows the equation of the monomol. reaction. But the velocity const. is much smaller for high concn. of the substrate than for low concn. S. MORGULIS

Apozymase and cozymase: Phosphorylation. C. NEUBERG AND A. GOTTSCHALK. *Biochem. Z.* 161, 244-56(1925).—Dried bottom yeast or its acetone prepn. can convert salts of H_3PO_4 and sugar quant. into hexosephosphate, but by washing the yeast with H_2O , a coenzyme may be removed with a consequent inhibition of the reaction. Dry top yeast, on the other hand, is unable to synthesize hexosephosphate even with added coenzyme. However, the acetone prepn. of top yeast with added coenzyme is able

to esterify the phosphate and sugar. Therefore, phosphorylation depends upon the presence of a cozymase, and some other zymase constituent. An ext. of rabbit muscle, when added to non-esterifying top yeast, enables it to form hexosephosphate to the extent of 50-60% of the theoretical amt. W. D. LANGLEY

Tryptic digestion at low concentrations of enzyme. III. R. EHRENBERG. *Biochem. Z.* **161**, 348-60(1925); cf. *C. A.* **19**, 3497.—The rates of action of a given amt. of trypsin upon casein, peptone and gelatin are different. The N compds. formed during hydrolysis are detd. by the method of Van Slyke. W. D. LANGLEY

Preservation in vitro and elective poison sensitivity of red blood corpuscles. O. LAVES. *Biochem. Z.* **161**, 416-45(1925).—To preserve blood without hemolysis, a soln. contg. 0.90% NaCl, 0.098% KCl, 0.098% CaCl₂ and 0.049% NaHCO₃ is best. The chlorides of morphine, methyl- and ethylmorphine hemolyze blood in increasing order. Added sucrose, reduces and replacement of the chlorides by the corresponding sulfates or phosphates stops, this hemolyzing action. With codeine, dionine, or quinine, the behavior of the cells is different. W. D. LANGLEY

The occurrence of a sulfur-containing amino acid in an alcoholic extract of yeast. S. ODAKE. *Biochem. Z.* **161**, 446-55(1925).—Besides the adenylythiomethylpentose, C₁₁H₁₆N₂SO₃, isolated by Suzuki, Otake and Mori (cf. *C. A.* **19**, 1867), another S contg. amino acid is now isolated. From 6000 kg. fresh yeast is obtained 0.6 g. of the pure acid, C₈H₁₁SNO₂, m. 272-3°. It is sol in H₂O and dil. alc., $\alpha_D^{16} = -11.77^\circ$. The Millon, biuret and FeCl₃ color reactions are neg. The acid gives white HgCl₂ or HgSO₄ salts, and is not pptd. by picric acid. Boiling with strong alkali does not remove the S. The salt, C₈H₁₀SNO₂, forms plates insol. in cold H₂O; the α -naphthyl isocyanate, C₁₀H₇NHCONH(C₈H₁₀S)COOH, m. 187°. This amino acid shows identical properties with that isolated by Muller (cf. *C. A.* **18**, 705) from casein and egg albumin. W. D. LANGLEY

The maltase of barley malt. H. PRINGSHEIM AND J. LEIBOWITZ. *Biochem. Z.* **161**, 456-8(1925); cf. *C. A.* **19**, 82.—A maltase is obtained which is active in the range of acidity $p_H = 3$ to 7.5, with its optimum activity at 4.5 to 5. W. D. LANGLEY

The role of the Donnan membrane equilibrium in osmotic processes in the living cell. VI. S AND V. V. BURKEVICH. *Biochem. Z.* **161**, 468-87(1925).—An application of the Donnan membrane equil. to the diffusion of salts through plant cells is studied. H₂SiO₃ favors the passage of the PO₄ ion into the plant root. H₂SiO₃ cannot functionally replace H₃PO₄ in plants. W. D. LANGLEY

The influence of temperature on the equilibrium between oxygen and hemoglobin of various forms of life. IVO MACELA AND ALBIN SELISKAR. *J. Physiol.* **60**, 428-42 (1925).—Oxygen dissocn. curves of dild. solns. of frog and human hemoglobin at 15°, 25° and 35° were detd. with some additional observations on fowl, tortoise and *Planorbis* hemoglobin. The affinity of frog hemoglobin for O₂ is much lower than that of human hemoglobin. The value of the equil. const. and the value of the tension of unloading, which is proportional to the const., increases for an increase of 10° 2.5 times in frog hemoglobin and 5.6 times in human hemoglobin over a range of temp. from 15° to 35°. The heat of reaction between 1 g. mol. of hemoglobin and O₂ is 27.4 cal. in human hemoglobin and 13.6 cal. in frog hemoglobin. J. F. LYMAN

Enzymic studies on the paired reactions in fat and carbohydrate metabolism. I. HANS V. EULER. *Biochem. Z.* **164**, 18-22(1925) S. MORGULIS

The destruction of hemoglobin by tissue extracts. V CALVO-CRIADO. *Biochem. Z.* **164**, 61-75(1925).—The destruction of hemoglobin by exts. of various tissues has been detd. with the spectrophotometer. Liver exts. were most potent in this respect; exts. from human skin were almost as active; other organs according to their effect on hemoglobin were lungs, kidneys and muscles. The addition of spleen ext. to the liver ext. greatly increased its destructive action. All organs can thus decompose hemoglobin, a fact which has an important bearing upon the extrahepatic origin of the bile pigments. S. MORGULIS

The separation of enzymes in barley malt. HANS PRINGSHEIM, ALEXANDER GENIN AND RAHEL PEREWSKY. *Biochem. Z.* **164**, 117-25(1925). S. M.

Chemical study of the age problem. RUDOLF EHRENBERG. *Biochem. Z.* **164**, 175-82(1925).—Very extensive material, both human and animal, has been analyzed for alc.-ether-sol. matter, N, P and Ca as well as the various amino acids. This material was taken from individuals of different ages, from intrauterine existence to extreme senility. A very extensive mass of data is presented but few general conclusions can be drawn with regard to the effect of age on chem. constitution. S. MORGULIS

Studies in the chemical topography of the brain. I. The lipid and total nitro-

gen of the cerebral cortex of man. HENRIETTE GORODISSKA. *Biochem. Z.* 164, 446-80(1925).—Functionally different portions of the human cerebral cortex have a distinct chem. compn. The greatest difference topographically is shown by the cholesterol, then by the alc.-sol. lipoids (cerebrosides and satd. phosphatides), total N and P of the unsatd. phosphatides. The motor area of the cortex (Gyrus centr. ant.) has the highest lipid and total N const. The smallest lipid content is found in the anterior association center (Polus front.). The sensory divisions (Cuneus and Gyrus centr. post.) are very similar in chem. compn., while the right and left parts are unlike and may even vary greatly in chem. constitution. At the age of about 50 years and later there is an increase in cholesterol and a slight diminution in total N and P content of the unsatd. phosphatides in the cerebral cortex. S. MORGULIS

The glucolytic power of blood. V. Experiments on adsorption of glucose by animal charcoal and erythrocytes, with special reference to glucolysis. YOSHIKANE KAWASHIMA. *J. Biochem. (Japan)* 5, 113-31(1925); cf. *C. A.* 19, 352.—Merck's animal charcoal adsorbs glucose at 9-13° very readily and abundantly, but at 37° this no longer occurs. The glucose is not oxidized catalytically under the influence of the surface. Erythrocytes remove only a small amt. of sugar at room temp. but at 37° they adsorb quickly an appreciable quantity. Old erythrocytes which have lost their glucolytic action still adsorb considerable amts. of glucose, so that glucolysis must be primarily associated with vital functions of the cell. S. MORGULIS

The mode of combination and determination of arginine in the protein molecule. SHOYO SAKAGUCHI. *J. Biochem. (Japan)* 5, 133-42(1925); cf. *C. A.* 19, 3506.—A colorimetric method is presented for the detn. of arginine. The best results are obtained with 5 cc. of a 1% protein soln., 2 cc. 15% NaOH, 5 cc. 0.15% α -naphthol soln. and an amt. of NaOCl appropriate for each protein. (Edestin 2.4-2.6 cc. 0.3 N; fibrin 1.8-2.0 cc.; gelatin 1.4-1.6 cc.; gliadin 1.6-1.8 cc.; glutenin 1.8-2.0 cc.; casein 1.8-2.0 cc., etc.) This reaction is obtained with a free guanidine group, and since the total arginine content of a series of proteins runs parallel with the amt. of free guanidine it is concluded that in the protein mol. the guanidine portion of the arginine must be free. S. MORGULIS

Arginine-free protein. SHOYO SAKAGUCHI. *J. Biochem. (Japan)* 5, 143-57 (1925).—Arginine-free protein has been prepd. by treating various proteins with NaOCl in the presence of an excess of free alkali. The excess of NaOCl is apparently without any effect. Arginine-free protein made from casein, ovalbumin, edestin, etc., has certain characteristics in common. It is insol. in acidified water and gives practically no biuret test or the author's color reaction with α -naphthol. It is hard to digest with pepsin but is much more easily digested by trypsin. All the arginine-free proteins show a very similar elementary compn.: C 50.41-51.97, H 6.38-6.50, N 13.75-14.11, S 0.45-1.78%. The base-binding capacity (phenolphthalein being used) was 21.08 cc. 0.1 N Ba(OH)₂ for 1 g. of arginine-free casein, 21.91 cc. for ovalbumin, and 24.48 cc. for edestin. In the hydrolytic decompn. of the arginine-free proteins alanine, valine, leucine, proline, phenylalanine, aspartic and glutamic acids and lysine were demonstrated. S. MORGULIS

Hydrolysis of protein with alkali. SHOYO SAKAGUCHI. *J. Biochem. (Japan)* 5, 159-69(1925).—The guanidine portion of the arginine in protein is less easily detached by the action of alkali on the protein than on the free amino acid. Arginine in gelatin is more easily attacked than in other proteins, which may be due to the fact that guanidine is readily hydrolyzed from this protein, or that gelatin under the action of alkali breaks up into peptides of much smaller size. The guanidine is completely removed from the arginine of several proteins acted upon by alkali while the peptide linkage of the protein mol. itself remains unaffected. Guanidine-free proteins have been prepd. from casein, ovalbumin, edestin, etc., which all possess certain characters in common. Although these all fail to give Sakaguchi's NaOCl color reaction, they give positive tests with most other color reactions. S. MORGULIS

Studies in comparative biochemistry. I. Occurrence of arginase in different organisms. YUZO SENDJU. *J. Biochem. (Japan)* 5, 229-44(1925).—Arginase was found in birds only in the kidneys. In amphibians this enzyme is present in the liver and to a limited extent also in the kidney. In reptiles arginase is found in several organs but in diminishing aints. as follows: kidney, liver, spleen and pancreas. Fish liver contains an enzyme which causes hydrolysis of arginine. This enzyme is also present in *Aspergillus oryzae*, but not in *B. coli comm.* S. MORGULIS

Composition of human brain. L. LEMATTE AND L. BEAUCHAMP. *Compt. rend.* 181, 578-80(1925).—Analysis of the brains of 1 man of 80 years and of 3 adults showed that the quantities of the different mineral constituents vary within narrow limits. P

is the dominant inorg. element. Age has little effect on the compn. of the brain, that of the 80-year-old subject being slightly richer in Na, K and P. L. W. RIGGS

The reaction of potassium ferricyanide with blood pigments. MAURICE NICLOUX AND JEAN ROCHE. *Compt. rend.* **181**, 823-6(1925); cf. *C. A.* **19**, 3302, 3505, 3530.—When carbonylhemoglobin (HbCO) is treated with $K_3Fe(CN)_6$ for each cc. of O received by the HbCO, 2 cc. of CO are produced. Conclusion: The formula of methemoglobin is HbO or Hb(OH)₂ and this pigment contains half the O of oxyhemoglobin. L. W. RIGGS

Aluminium in organic life. JULIUS STOKLASA. *Intern. Rev. Sci. Practice Agr.* **3**, 654-62(1925).—Plants which prefer dry surroundings have a low Al content. The hygrophytes on the contrary are noted for a high Al content, especially in the root. A sp. porosity of the cells of the root system to Al appears to exist. An excess of Fe causes plasmolysis in the plant, but if Al is present this plasmolysis does not occur. The Al appears to hinder the entrance of Fe and Mn compds. into the cell. Al participates in the formation of coloring matter of flowers. In the animal world both beetles and birds had more Al if the colors were blue, violet, red and blue-green than was the case with other colored pigments. In the mineral kingdom Al is a constituent of the brightest colored gems. Al appears to be injurious to plants if SO_3 or SO_4 ions are present. L. W. RIGGS

Solubility of proteins in fat solvents. D. DEUTSCH. *Magyar Orvosi Archivum* **26**, 525-6(1925); cf. *C. A.* **19**, 1216. —In the presence of certain electrolytes, such as H_2SO_4 , HNO_3 , etc., non-aq. solns. of albumins were produced. Whether the albumin is sol. only in water, or also in fat solvents, depends on the presence of electrolytes and on their quantity. L. W. RIGGS

Present pigmentary problems. I. Formation of the melanins. JEAN VERNE. *Rev. gen. sci.* **36**, 621-43(1925).—In this review animal and vegetable pigments are classed in 7 groups according to chem. origins. The relations of these groups to each other are described, and the formation of melanins from the chem. point of view, both *in vitro* and *in vivo*, is discussed. Also the formation of melanins from the histologic point of view is considered. L. W. RIGGS

Enzymes of the stomach of infants. K. WALTHER. *Magyar Orvosi Archivum* **26**, 522-4(1925).—The stomachs of healthy new-born infants contain chymosin. The quantity increases with age and is independent of individual acidity. It is less in breast-fed than in artificially fed infants. The lipolytic action of the stomach contents of breast-fed children is intense. Here the lipase of the mother's milk plays a large part. The lipase varies with the amt of fat in the food. The amylase content of the stomach arising from swallowed saliva behaves similarly to the chymosin. Amylase is found in very young infants and it increases with age. In diseased infants the rennet content remains about the same, the lipase decreases and the amylase varies with the lipase. L. W. RIGGS

Imitations of cell division and of the germination of spores with calcium fluosilicate. A. L. HERRERA. *Atti. accad. Lincei* [6], **2**, 387-93(1925).—A detailed illustrated description of these imitations. E. J. WITZEMANN

The bile acids (WIELAND, SCHLICHTING) 10.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Some special features of blood sugar determination. D. G. COHEN TERVAERT. *Nederland. Tijdschr. Geneeskunde* **69**, II, 1110-2(1925).—The following reduction table for calculating glucose from reduced copper is given (referring to the method of Shaffer and Hartmann, *C. A.* **15**, 1328).

Mg. Cu	0.05	0.10	0.15	0.20	0.3	0.4	0.5	0.6
Mg. glucose	0.09	0.116	0.142	0.168	0.221	0.273	0.327	0.395

R. BEUTNER

The microestimation of glucose after the method of L. Bang. E. COHN AND A.

WAGNER. *Biochem. Z.* **160**, 43-51(1925).—A critical study of the conditions necessary for accurate results with Bang's method. F. A. CAJORI

The determination of nitrogen after D. Acél. F. HIMMERICH. *Biochem. Z.* **160**, 105-12(1925).—With Acél's micro method (*C. A.* **15**, 3649) total N was detd. with an error of 2 to 3% when all precautions as to purity of reagents, nesslerization and colorimetry were carefully observed. F. A. CAJORI

Preparation of the ovarian hormone in aqueous solution. BERNHARD ZONDEK AND BENNO BRAHN. *Klin. Wochschr.* **4**, 2445-6(1925).—Methods are described for obtaining the ovarian hormone from placenta and from the ovary. The placenta is dried and extd. with alc., Et_2O and CHCl_3 . The combined exts. are concd. The oily residue is extd. with AcOH , the ext. clarified, neutralized with Na_2CO_3 and concd. to a suitable vol. It contains the hormone. Follicular fluid is freed from protein by heating at 80° in the presence of acid, filtering and concg. the filtrate to a suitable hormone content. MILTON HANKE

Functional stomach diagnosis. I. E. WOENCKHAUS. *Z. klin. Med.* **100**, 135 (1924).—The Cl values in the gastric juice are discussed. II. *Z. ges. expl. Med.* **44**, 369-77(1925).—A description is given of 2 colorimetric methods for the detn. of the secretion of gastric juice. Acetylindoxyl, which gives an indican reaction, was used in 0.005% soln. The second method, using FeCl_3 , was preferred as the FeCl_3 is more stable, very sensitive and non-toxic. HARRIET F. HOLMES

A simple process for the preparation of the new oxalate from human urine. W. O. MOOR. *Biochem. Z.* **159**, 245-6(1925); cf. *C. A.* **19**, 2215.—The substance which occurs in urine, and is designated by U, may be isolated as the oxalate from an amyl alc. soln. Its properties are not described. W. D. L.

Simple method for taking blood in the Hagedorn-Jensen blood sugar determination. G. FRITZ AND B. PAUL. *Biochem. Z.* **159**, 247-9(1925).—A centrifuge tube with a micro pipet inserted is used to collect both the blood, and the alk. ZnSO_4 soln. The whole is then centrifuged to obtain a clear soln. for the titration. W. D. L.

The sodium nitroprusside test for the presence of and for the determination of total acetone in urine and in certain other body fluids. N. O. ENGFELDT. *Biochem. Z.* **159**, 257-75(1925).—The sensitivity of Na nitroprusside in Legal's test for $\text{AcCH}_2\text{CO}_2\text{H}$ is 6 mg. per l. and for $(\text{CH}_3)_2\text{CO}$, 100 mg. per l. Applied as the Rothera test, the sensitivities are 1 and 100 mg. per l., resp. The color with $\text{AcCH}_2\text{CO}_2\text{H}$ develops to its max. intensity in 10 min. and then changes after $\frac{1}{2}$ or 1 hr. to a yellow or green, while with Me_2CO , the color reaches its max. in $\frac{1}{2}$ to 1 hr. and fades after 3 hrs. Both tests must be applied to urine directly, not to a distillate. The Rothera test is superior to Legal's test. A roughly quant. colorimetric method for the detn. of total acetone in urine is developed, with solns. of KMnO_4 as standards of comparison. W. D. L.

The determination of small quantities of arsenic in animal organs. F. PRIBYL. *Biochem. Z.* **159**, 276-9(1925).—Strips of copper foil, when placed in solns. contg. known amts. of As, become coated with As. The darkness of each deposit depends upon the concn. of As present. The deposits may be compared with those obtained from solns. with known amts. of As, and an est. of the As content of each made. Then the deposited As may be dissolved in 0.1 N I soln. as in the method of Rein and titrated with $\text{Na}_2\text{S}_2\text{O}_3$. The soln. thus obtained may also be used in the Marsh test. W. D. L.

A colorimetric method for the determination of bile salts in blood. P. SZILÁRD. *Biochem. Z.* **159**, 325-6(1925).—Into 50 cc. abs. alc. are dropped without stirring 5 cc. blood serum. The whole is heated on the H_2O bath to boiling, animal charcoal is added, the soln. is filtered and the residue washed with abs. alc. The filtrate is concd. on a H_2O bath to 15 cc., cooled, and 100 cc. Et_2O added to ppt. the bile salts. After the Et_2O soln. has been chilled for 3 hrs. the soln. is filtered, and the residue dissolved in 5 cc. of AcOH with warming. This soln. is then carried through the Lifschütz color reaction, i. e., BzO_2 is added, the soln. heated to boiling, cooled quickly and 1 cc. of $\text{H}_2\text{SO}_4\text{-AcOH}$ (1:10) mixt. added whereupon the soln. becomes green. The max. color occurs in about 15 min., and it may be hastened by the addn. of a drop of 2.5% FeCl_3 in AcOH soln. The colored soln. is now compared by the use of a colorimeter, with a soln. of pure bile salts similarly prepd. W. D. L.

A method for the determination of protein in 0.1 cc. of serum. S. HOLM AND H. TÓMASSON. *Biochem. Z.* **159**, 472-81(1925).—A diluted serum is treated with HNO_3 (sp. gr. = 1.18) so that a bottom layer of HNO_3 is formed. The turbidity which appears in a definite time is compared with that produced in a soln. of known protein content and similarly treated. W. D. L.

A micro-method for the determination of chlorides in body fluids. A. NIRSCHKE.

Biochem. Z. **159**, 489-90(1925).—The method of Bang is modified so that instead of pptg. the Cl as AgCl and weighing, it is titrated with AgNO₃, with KCrO₄ as an indicator.
W. D. I.

Determination of enzymes in microorganisms. I. Catalase content of bacteria. A. I. VIRTANEN AND H. KARSTRÖM. *Biochem. Z.* **161**, 9-46(1925).—As a measure of the activity of cells with respect to catalase, the ratio catalase activity = reaction const. K /no. cells is used. K is independent of the concn. of substrate. The catalase is buffered to $p_H = 6.5$, and the excess H₂O₂ is detd. by titration with KMnO₄. The age or growth temp. of the bacteria has no relation to their catalase content. Increase of temp. lowers the value of K and for a number of strains K is not const., but decreases with time. Buffer at a concn. of $M/150$ is more effective than at a concn. of $M/15$. Protoplasmic poisons such as CHCl₃ and xylene are without effect upon the catalase activity. The enzyme becomes inactivated above 60°. Added glucose does not affect the reactivity. Under anaerobic conditions, the activity is increased.
W. D. I.

Hematoporphyrin. RENÉ FABRE. *Compt. rend.* **181**, 623-5(1925).—A spectrophotometric study was made for the purpose of identifying hematoporphyrin in various products of the organism.
L. W. RIGGS

Salivary index of renal function. G. PACETTO. *Riforma Medica* **41**, 649(1925); *J. Am. Med. Assoc.* **85**, 934 —Concordance between the percentage of urea in the blood and in the saliva was complete in 89% of 55 subjects. In the others the salivary index showed retention while the blood showed only normal figures. As the sources of error tend to raise the salivary index, a normal figure excludes retention.
L. W. RIGGS

Methods for the determination of the total quantity of blood. GY. PETRÁNYI. *Magyar Orvosi Archivum* **26**, 346-59(1925).—The following methods are described: (1) Welcker's, the so-called abs. method which det. the total blood from the hemoglobin content of the total blood obtained by bleeding and by the washing of the blood vessels *in vivo* with physiol. saline. (2) Plasma methods which calc. the blood quantity from the degree of diln. of a certain injected soln. This soln. may be a dye, hemoglobin or a colloidal soln., in which case the refraction of the serum is detd. (3) The CO method, with which a detd. quantity of CO is inhaled and from the CO content of a known quantity of blood are calcd. the degree of dispersion and the quantity of blood. (4) The relative detn., from which after the injection of a NaCl soln. from the changes found in the concn. of the blood (hemoglobin, red blood cells and lowering of the f. p.) the total quantity is calcd.
L. W. RIGGS

Micro-method for the determination of the globulin content of the spinal fluid. I. NÁDOR. *Magyar Orvosi Archivum* **26**, 519-21(1925).—For this diaphanometric method 10 tubes are prepd. contg. 0.01-0.1% of serum globulin dilns. To an eleventh tube is added 2 drops of the fluid in question, then all of the tubes receive 1 cc. of 6.75% phenol and the corresponding opacity is noted.
L. W. RIGGS

Conditions of validity of Macallum's microchemical test for calcium. MYRA M. SAMPSON. *Science* **62**, 500-1(1925); cf. following abstr.—Purpurin forms a distinctive reddish purple compd. with Ca only in alk. solns. *Paramecia* transferred from an alk. medium contg. Ca and treated with purpurin are stained locally, while those transferred from a medium contg. NaCl, KCl or sucrose are diffusely stained.
L. W. RIGGS

Purpurin method of localizing calcium. A. B. MACALLUM. *Science* **62**, 511(1925); cf. preceding abstr.—M. states that the method was first advanced by Grandis and Mainani (cf. *Arch. ital. biol.* **34**, 73; **38**, 143(1902)).

C—BACTERIOLOGY

A. K. BALLS

Reduction experiments with bacteriophages. L. GÓZONY AND L. SURÁNYI. *Magyar Orvosi Archivum* **26**, 301-5(1925).—The reduction power is a characteristic property of living cells. Expts. have shown that the bacteriophage alone is not able to reduce. Young bouillon cultures with bacteriophages reduce better than cultures with boiled phages, because the bacteria grow better in the first 2 hrs. in the presence of phage.
L. W. RIGGS

A study of various strains of *Bacillus radiculicola* from nodules of alfalfa and sweet clover. J. W. STEVENS. *Soil Science* 20, 45-65(1925).—Thirteen strains of nodule bacteria of the alfalfa-sweet clover group were distinctly divisible into 2 groups by cross-agglutination tests. One strain (A) produced abundant raised, pearly white growths, the other (B) moderate, thin, whitish growths. No change in the organisms was noticed in 3 yrs. The "fast growers" of group A were acid sensitive, growing equally well from p_H 6.5 to 9.0 while the "slow growers" of group B grew best at p_H 6.5 and showed growth at p_H 5.5 after 4 weeks, an acidity which completely prevented the growth of group A. Alfalfa grown in sand cultures fixed almost twice as much N when inoculated with organisms of group A as with group B. RICHARD BRADFIELD

The nodule bacteria of soy beans: I. Bacteriology of strains. WM. H. WRIGHT. *Soil Science* 20, 95-129(1925).—All strains of *Pseudomonas radiculicola* of *Soja max* studied were identical morphologically but differed physiologically. There are 2 rather well-defined groups, each characterized by a different critical p_H ; different inhibiting consens. of the dyes are characteristic of the type, especially crystal violet; different gum-producing ability and different serological reactions are obtained. No single lab. test was sufficient to differentiate the 2 types, but all known properties had to be detd. The 2 groups do not represent 2 species but distinct biotypes, each of which varies around a mean of its own. **II. Nitrogen-fixation experiments.** *Ibid* 131-41.—Greenhouse and field studies were carried on for 3 yrs. with 6 strains of the above organism on 3 varieties of soy beans. Two strains (Type B) consistently fixed less N than the rest (Type A). The size, no. and distribution of nodules produced by type A are different from those of type B. The field and greenhouse studies confirm the lab. studies in indicating 2 biotypes in the 6 strains studied. R. BRADFIELD

Modifying *Rhizobium radiculicola*. VICTOR BURKE AND LLOYD BURKEY. *Soil Science* 20, 143-7(1925).—The tolerance of *R. radiculicola* for gentian violet was greatly increased by growing it for several generations on a 1-10,000 gentian violet agar. The dye-tolerant culture made as good growth in a 1-1000 as the original did in a 1-10,000 culture. This tolerance was lost after growing only 3 generations on a dye-free agar. The modification of bacterial cultures by the process of exposure and selection or dissociation offers a promising field for experimentation. R. BRADFIELD

Growth stimulation of *Aspergillus niger* by a vitamin B preparation. NELLY J. SCHELLING. *Bull. Torrey Bot. Club* 52, 291-310(1925).—Vitamin B from yeast stimulated both vegetative growth and reproduction. Excess of the vitamin was used as a source of N. There is a slight increase in gain in dry weight per gram sugar consumed when vitamin is present. The effects of the vitamin are two-fold: increase of org food supply and stimulation analogous to that produced by small amts. of such toxic substances as Zn salts. JOSEPH S. CALDWELL

Fermentation of galactose by yeast after previous treatment with this sugar. HANS V. EULER AND RAGNAR NILSSON. *Z. physiol. Chem.* 143, 89-107(1925).—Fresh yeast which has been cultivated in the presence of galactose and has acquired the property of fermenting it, does so more rapidly on the addn. of biocatalyst Z but not on addn. of purified co-zy-mase. Expts. where the preliminary treatment occurred in the presence of PhOH confirm the earlier work of Euler and Laurin in which the adaptation to galactose occurred also when the yeast is not capable of propagation. Sterile dried yeast can acquire the property of fermenting galactose by preliminary treatment with galactose and then attains equal fermenting power with respect to both hexoses. A. W. DOX

Acetic acid fermentation and allied phenomena. CARL NEUBERG AND FRITZ WINDISCH. *Naturwissenschaften* 13, 993-6(1925).—Review of recent work. *Bacterium ascendens*, *pasteurianum* and *xylinum* under anaerobic conditions all convert AcH into equal parts EtOH and AcOH (dis-mutation). This reaction also takes place in acid medium or in the presence of air; in the last case a rather slow alc. oxidation occurs simultaneously. Similar dismutation was found for higher aldehydes (isovaleric and isobutyric); the aldehydemutase is also present in *Bacterium coli*, *lactis aerogenes* and *propionicum*. The great biological significance of dismutation instead of simple oxidation is emphasized. B. J. C. VAN DER HOEVEN

Influence of thyreoidin, cerebrin and cordin upon the anaerobic respiration of yeast. L. P. ROSENOW. *Biochem. Z.* 159, 235-9(1925).—Blood serum >cordin>cerebrin> and thyreoidin stimulate in the order given the production of CO₂ by the action of yeast on beet sugar. W. D. L.

Fungi and bacteria using quinic acid. V. BUTKEVICH. *Biochem. Z.* 159, 393-413(1925); cf. C. A. 19, 91.—The fungi which can utilize quinic acid convert it into phenolic substances and those which grow best can utilize the quinic acid as a source of C. The

no. and relative positions of the OH groups in phenols det. whether or not they may be utilized. Catechol in moderate concns. is toxic, but at low concns. may be completely utilized by *Aspergillus niger* and *Citromyces glaber*. Certain bacteria which grow upon quinic acid can oxidize glucose to gluconic acid. There seems to be a similarity between the metabolism of quinic acid and of carbohydrates. W. D. LANGLEY

Formation of acetylmethylcarbinol and 2,3-butylene glycol in the metabolism of yeast. A. J. KLUYVER, H. J. L. DONKER AND F. V. HOOFT. *Biochem. Z.* **161**, 361-78 (1925); cf. *C. A.* **19**, 3510.—To show the presence of $\text{CH}_3\text{COCH}(\text{OH})\text{CH}_3$ in a yeast mash, protein is removed by boiling, and the dissolved $\text{CH}_3\text{COCH}(\text{OH})\text{CH}_3$ oxidized with FeCl_3 to $\text{CH}_3\text{COCOCH}_3$, which is distd. and converted to Ni dimethylglyoxime. It is shown that pure $\text{CH}_3\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CH}_3$ isolated from a mash is not converted by Br to $\text{CH}_3\text{COCOCH}_3$ as was formerly believed, although in the presence of ferric salts and NaOAc the reaction does take place provided unchanged sugar or certain easily oxidizable compds. are absent. The excess Br is removed with NaHSO_3 and the $\text{CH}_3\text{COCOCH}_3$ formed distd. as before. In the presence of a H acceptor, such as methylene blue or S, $\text{CH}_3\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CH}_3$ is formed from accumulated AcH during yeast fermentation of glucose or fructose. No mannitol was formed from fructose. With aeration some AcH is blown off so that its reduction products are formed to a smaller extent, and there is less butylene glycol than in non-aerated yeast.

W. D. LANGLEY

Studies in the biochemistry of *Bacterium pyocyaneum*. Contribution to the problem of its metabolism and its relation to intramolecular respiration. OSKAR ACKLIN. *Biochem. Z.* **164**, 312-70 (1925).—The growth activities of biologically well-defined strains of *B. pyocyaneum* have been carefully studied in chemically simple nutritive solns. of different p_{H} . It was thus demonstrated that one of the catabolic products, especially in a nitrate-lactic acid system, is pyruvic acid which is converted into alanine (combining with NH_4^+) and becomes incorporated into the protein of the bacterium. It has also been shown that CH_3CHO plays the usual important role in the intermediate metabolism of these organisms. In an NH_4Cl lactic acid system the organisms convert only $1/3$ of the N present as nitrates into their body protein. *B. pyocyaneum* retains its virulence and ability to produce toxic substances even on chemically simple media free from protein N.

S. MORGULIS

Effect of radium on pathogenic protozoa in culture. R. BRUYNOGHE AND A. DUBOIS. *Compt. rend. soc. biol.* **93**, 849-50 (1925).—Exposure to Ra radiation of a 5-millicurie dose for 48-62 hrs. produced no definite results on cultures of *Leishmania tropica*; it retarded *Trypanosoma inopinatum* non-infectious and not cultivable; *Spirochaeta ictero-hemorrhagiae* from rabbit serum retained its motility but lost the ability to be cultivated under similar treatment, and became non-infectious for the guinea pig.

S. MORGULIS

Effect of radium on filterable virus. R. BRUYNOGHE AND LE FÉVRE DE ARRIC. *Compt. rend. soc. biol.* **93**, 852-4 (1925).—Ra emanation destroys the filterable virus of rabbits as well as other filterable viruses.

S. MORGULIS

A study of anaerobic bacteria. J. H. BROWN. *J. Bact.* **10**, 513-42 (1925).—No toxin-forming anaerobes were found in the intestinal tract of the calf studied. Both proteolytic and saccharolytic anaerobes were found at all levels, but the former were more abundant in the cecum and large intestine. More than half the strains studied could hydrolyze the fat of cow milk. The titratable acidity is unreliable for detn. of fermentation by anaerobes, since they often produce large increases in the buffer index of media. Disappearance of carbohydrate from the medium is the best index of fermentation, and as much as 3% is sometimes necessary. Neither NH_3 nor amino-acid production is a good index of proteolysis. The formol titration is much better. Some of the proteolytic organisms produce more gas than *C. welchii* though more slowly. The proportion of CO_2 to other gases above the medium is least at the beginning of gas formation, increases often to 100% of the gas given off during the intermediate period, and again decreases toward the end of the gas-forming period. Whether all the gas comes from carbohydrates is questionable.

JOHN T. MYERS

The electric current (apart from the heat generated), a bacteriological agent in the sterilization of milk and other fluids. J. M. BEATTIE AND F. C. LEWIS. *J. Hyg.* **24**, 123-37 (1925).—In an elec. lethal tube bacteria are destroyed much below their thermal death point.

JOHN T. MYERS

The bacteriology of subacute infective endocarditis. H. D. WRIGHT. *J. Path. Bact.* **28**, 241-78 (1925).—Media for blood cultures which contain trypsin or Na citrate are slightly superior to those which do not. If 20% trypsin is added to whole blood streptococci are not killed.

JOHN T. MYERS

The antiseptic action of salicylic and benzoic acids and of paper impregnated with salicylic acid against molds. M. BORNAND. *Tech. Ind. Schweiz. Chem.-Ztg.* 1925, 239-41.—In beef ext. a concn. of 0.05% of BzOH or $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ prevents the development of *B. coli* or *B. subtilis*, but 0.15% is required to inhibit that of *Saccharomyces cerevisiae*. The development of molds in beer wort is stopped only by 0.25% of either acid. Paper impregnated with either, used for covering preserves, was found to be without action. W. B. PLUMMER

Bacteriophage of d'Herelle. V. Effect of electrolytes on the rate of inactivation of bacteriophage by alcohol. JACQUES J. BRONFENBRENNER AND CHARLES KORB. *J. Exptl. Med.* 43, 71-86(1926); cf. *C. A.* 19, 3512.—Addn. of neutral salts to the lytic filtrate results in an increased rate of inactivation of the latter when EtOH is added to it. This effect of salts is the more marked the higher the valency of the cation. Conversely, removal by dialysis of salts originally present in the lytic filtrate tends to render lytic agents less sensitive to EtOH. Restitution of the original salt content to the dialyzed filtrate tends to bring the sensitiveness to EtOH in the dialyzed filtrate to the level of the non-dialyzed control. Inactivation of the lytic agent by EtOH thus appears to depend directly on the rate of pptn. of the coagulable constituents of the medium and is not the result of a direct toxic action of EtOH on "*bacteriophagum intestinale*." Considered in association with earlier work, these results speak in favor of the chem. nature of the agent of transmissible lysis. C. J. WEST

The presence of sulfate-reducing bacteria in oil-field waters (BASTIN, *et al.*) 8.

D—BOTANY

B. M. DUGGAR

Antagonism of the walnuts (*Juglans nigra* L. and *J. cinerea* L.) in certain plant associations. A. B. MASSEY. *Phytopathology* 15, 773-84(1925).—Wilting and subsequent death of potatoes, tomato, alfalfa and other crop plants in a circular area about walnut and butternut trees extending beyond the longest branches are not due to insufficient water supply nor to accumulation of toxic products from decaying leaves and shells. The root systems of affected plants were, in all cases, in immediate contact with the tree roots. Water cultures of tomato with bits of walnut bark or roots added showed prompt wilting and death of roots. No such effects occurred when bits of root or bark were added to soil pots in which plants were grown. The toxic effects are probably due to juglone. JOSEPH S. CALDWELL

Recent advances in science: Plant physiology. WALTER STILES. *Science Progress* 20, 417-23(1926).—Review of recent work on permeability. JOSEPH S. HEPBURN

Experiments on carbon dioxide assimilation. OTTO WARBURG. *Naturwissenschaften* 13, 985-93(1925).—A review of work done in recent years by W. and Negelein on CO_2 assimilation by *Chlorella* suspensions. The $v-i$ curve (velocity of assimilation against light intensity) consists of two parts; at low i values v goes up linearly with i and is independent of temp. θ ; at high i values $dv/di = 0$ and $dv/d\theta > 0$ (Blackman reaction). For the first reaction the specific photochem. action (cc. CO_2 decomposed/cal. light energy absorbed by the chlorophyll) runs from 117 ($\lambda = 660 \mu\mu$) to 67 ($\lambda = 436 \mu\mu$). This means that in the red 4.4, in the yellow 4.3 and in the blue 5.1 quanta of light energy are necessary per mol. CO_2 for complete reaction into glucose. The higher value in blue may be explained from absorption by secondary pigments, xanthophyll and carotins. From the narcotization of the cells by chemically indifferent, but highly adsorbable, substances it is concluded that the photochem. reaction takes place on solid surfaces. The Blackman reaction is as strongly influenced by narcotics (at least 10 times more than the cell respiration) and also (contrary to the photochem. reaction) by HCN and H_2S ; it probably is essentially a catalysis by some heavy metal (Fe). This reaction has between 10° and 30° an almost linear $v-\theta$ curve. These properties are all similar to those of H_2O_2 decompn. by *Chlorella* catalase; for these reasons the reaction scheme of Willstätter and Stoll, formaldehyde peroxide $\rightarrow \text{O}_2 + \text{formaldehyde}$, gives the best explanation of the facts. B. J. C. VAN DER HOEVEN

The water-soluble phosphatide from the root of the sugar beet. I. V. GRAFE AND V. HORVAT. *Biochem. Z.* 159, 449-67(1925).—A phosphatide from the sugar beet was pptd. and purified as the Pb salt. It was hydrolyzed with 5% H_2SO_4 and oleic and palmitic acids, choline, and glycerophosphoric acid were isolated. Hydrolysis with 20% H_2SO_4 gave in addn. glutaric acid, but the carbohydrate could not be detected. The empirical formula obtained for the Pb salt of the phosphatide is $\text{C}_{77}\text{H}_{153}\text{O}_{16}\text{P}_2\text{-NPb}_4$, which indicates a dimolecular structure. A second substance, called a B phos-

phatide, is obtained and this does contain a reducing substance which seems to be a carbohydrate; it has not yet been isolated from the hydrolysis products. W. D. L.

Some alleged Philippine poison plants. M. M. KALOW AND F. M. SACAY. *Philippine Agr.* **14**, 421 7(1925). - Field tests for HCN and saponin were made upon many Philippine plants and the results with other properties of certain poisonous plants are listed. A. L. MEHRING

Temperature and metabolic balance in living plant tissues. FRANKLIN KIDD AND CYRIL WEST. *Proc. Fourth Intern. Congress of Refrigeration* **1**, 170-85(1924). - From a brief review of results obtained in many fields of investigation with regard to the reaction of plant tissues to temp. and also from purely theoretical considerations K and W. conclude that: (1) Temp. not only affects the speed of metabolism, but also controls the metabolic balance and hence influences directly the chem. constitution of plants, their structure and the precise course of their developmental sequence in growth, maturation and senescence. (2) There is probably an optimum av. temp., differing in different cases, for yield of particular plant products arbitrarily acquired by man. (3) The range of temp. within which plants can complete their life-cycle is limited. (4) Beyond these limits, differing in different cases, displacement of the metabolic balance results sooner or later in injury and death. (5) No general conclusion can be given at present as to the effect of change of temp. on metabolic balance and chem. compn. The effect may differ in different cases, but investigations agree in showing that in carbohydrate metabolism the balance alters with fall in temp. in the direction of increased hydrolysis. (6) Both the change in chem. compn. at low temp. in regard to such substances as sugars, pectins, substances responsible for flavor, etc., and the possibility of injurious effects at low temps. above the f. p. are factors of importance in the cold storage of fruit and vegetables needing further study. Bibliography of 21 references. A. PAPINEAU-COUTURE

Heritable chlorophyll deficiencies in seedling cotton. G. N. STROMAN AND C. H. MAHONEY. Texas Agr. Expt. Station, *Bull.* **333**, 22 pp.(1925).—The hereditary behavior of 2 deficiencies in green coloring matter in seedling cotton is reported. These 2 characters, one of which is yellow seed leaves instead of the usual green and the other the lack of green color in certain portions of the seed leaves, are important defects not only because of their fundamental scientific interest but also because the presence of these characters in a field of cotton lessens the stand and vigor of the plants. The 2 characters mentioned are shown to be inherited and the relations of the genetic factors concerned have been discovered. These factors thus form a true basis for future genetic work in cotton. J. J. SKINNER

A new form of iodine in Laminaria. I. P. FREUNDLER, Y. MÉNAGER, Y. LAURENT AND J. LELIÈVRE. *Bull. soc. chim.* **37**, 1466-82(1925).—If freshly harvested *Laminaria* (especially *L. flexicaulis*) is stored in a closed container for 10 to 30 days, it will then show 50 to 150% more I on analysis than did the fresh material. It is thought that in the living tissue under the influence of sunlight part of the I is intimately bound with certain org. and inorg. constituents and that it is thus rendered incapable of analysis. Three methods of analysis are given. J. J. WILLAMAN

E -NUTRITION

PHILIP B. HAWK

The nomenclature of the vitamins. E. C. VAN LEERSUM. *Nederland. Tijdschr. Geneeskunde* **69**, II, 2418-20(1925).—L. points to the confusion existing in naming the vitamins; "vitamin D," e. g., signifies different substances according to Funk and according to Steenbock. R. BEUTNER

The influence of the Degerma process on the antiscorbutic properties of milk. ERICH LOEWY. *Klin. Wochschr.* **4**, 1776(1925).—The Degerma process appears to involve heating the milk for 30 min. to 63-5°, cooling and adding Al in safe (?) amts. The milk is deficient in vitamin C. MILTON HANKE

Blood picture of rats with experimental rickets. E. MAURER, ST. DIEZ AND TH. BERENDT. *Klin. Wochschr.* **4**, 1869-70(1925).—The blood of rats, kept for 7 weeks on a rickets-producing diet, contains nucleated erythrocytes, erythroblasts and myelocytes. The erythroblasts occur, after 3 weeks, in 50% of the animals and after 5 weeks in all of the animals. MILTON HANKE

Scurvy in guinea pigs. KARL SCHMITT. *Klin. Wochschr.* **4**, 2104-5(1925).—Fresh goat milk protects guinea pigs perfectly against scurvy. Buttermilk is only partially protective. The animals live 6-7 weeks as compared with 3-4 weeks on an identical diet but without buttermilk. Children do not develop scurvy when butter-

milk is given as the only source of vitamin C. The guinea easily that facts accumulated for this animal cannot be tr reservations.

Vitamin content of human milk. L. F. MEYER AND E. 4, 2380-3(1925); cf. C. A. 19, 1293.—Infant guinea pigs die exclusively with human milk. There is no evidence of scurv starvation. Human milk which contains 1.5% protein, 3.5% fat and 6.0% carbohydrate is especially adapted to an animal that develops slowly. The guinea pig doubles in wt. in 13 days; hence it requires a diet rich in protein such as guinea pig milk which contains 4.7% protein, 7.4% fat and 2.3% carbohydrate. Human milk, augmented by the addn. of protein, gives normal growth curves for guinea pigs. Human milk is not deficient in vitamin C.

Recent advances in science: Animal nutrition. H. E. WOODMAN. *Science Progress* 20, 429-35(1926).—Review of recent work on vitamins, growth, nutrition and the cooking of stock foods.

Vitamin B. P. A. LEVENE AND B. J. C. VAN DER HOEVEN. *Chem. Weekblad* 22, 575-6(1925).—A review (cf. C. A. 18, 3638; 20, 224).

Egg white vs. casein as source of protein in the diet of rats. HELEN S. MITCHELL. *Am. J. Physiol.* 74, 359-62(1925).—Egg white is only slightly less adequate than casein. When it furnishes 18% of the protein in a standard diet supplemented by yeast it is an adequate source of protein especially adapted for low mineral diets.

Irradiation of chicks with cod-liver oil. C. W. CARRICK. *Am. J. Physiol.* 74, 534-8(1925).—Chickens kept on a highly rachitic diet and fed near irradiated cod-liver oil in Pyrex flasks developed rickets later and in a less severe form than the controls. It is assumed that the antirachitic substance is some form of ultra-violet energy.

The distribution of vitamin B in the maize kernel. HILDA M. KROLL AND L. B. MENDEL. *Am. J. Physiol.* 74, 674-94(1925).—Feeding expts. have shown that in yellow maize practically all vitamin B of the whole grain is found in the embryo, while the bran contains only traces and the endosperm no vitamin at all. Loss of vitamin B through milling of white corn embryo appears possible.

Biochemistry of avitaminosis. VI. The influence of corn upon the nitrogen, creatinine, and creatine excretion of rabbits and upon the weight curve of guinea pigs. A. PALLADIN AND KATHARINA KRATINOWA. *Biochem. Z.* 159, 179-91(1925); cf. C. A. 19, 2364.—Growing rabbits placed upon a diet of corn lived for 50 to 70 days, and, during this interval, lost about 1/2 of their wt. The N excreted per unit of body wt., however, remained about const., whereas the creatinine coeff. increased from 21.7 to 24.8 in 3 weeks, fell to 13.4 in 3 more weeks and then increased again. No true avitaminosis was observed. The wt. of guinea pigs upon the same diet decreased quite uniformly and death again resulted in about 50 days. When the corn was heated in an autoclave, however, the wt. dropped suddenly and death occurred in 15 days. Corn was not a complete food and the death of the animals was thought to be due to the inadequacy of the proteins, as well as to the deficiency of vitamins C and A.

Influence of injected solutions of plant secretin upon the intermediary carbohydrate metabolism. M. DOBREFF. *Biochem. Z.* 161, 80-90(1925).—The amt. of sugar in the blood of pigeons is about doubled as a result of the injection of an ext. of spinach. This is true both of polyneuritic as well as normal birds. The same ext., however, when injected into dogs, raises the blood sugar level only slightly.

The relation of creatine to the metabolism of carbohydrates. A. PALLADIN. *Biochem. Z.* 161, 139-56(1925).—Dogs kept upon a carbohydrate-free diet with no excess of protein excreted creatine whereas with excess of protein over normal requirement they did not. This difference is probably due to the conversion of protein to carbohydrate. In the rat, the excretion of total N is hardly affected by lack of carbohydrates, but the excretion of creatine is again increased. The same changes occur when fresh meat, which contains creatine, is fed. Guinea pigs respond similarly. Glycerol and lactic acid, when fed in place of carbohydrate, also reduce the excretion of creatine. Rabbits kept cold and fed sugar showed a lower creatine excretion than when not fed sugar. Therefore, creatine is concerned with the metabolism of carbohydrates.

Vitamin potency of cod-liver oils. XVIII. Effect on vitamin potency of solid-pressing cod-liver oils. A. D. HOLMES AND M. G. PIGOTT. *Ind. Eng. Chem.* 18, 188-9(1926); cf. C. A. 19, 3520.—Six typical crude cod-liver oils were pressed under com. conditions by refrigeration in a brine-cooled tank and the solidified stearin was

sepd. from the non-freezing oil. The analyses of the crude oil and the pressed oil showed a slightly higher I no. and a higher n for the pressed oil although the differences were not marked. From a practical standpoint the vitamin A tests on white rats failed to indicate significant differences in the potency of the 2 types of oils.

H. B. LEWIS

The value of the minerals in fish meal for fattening pigs. H. R. DAVIDSON. *J. Ministry Agr.* 32, 708-13 (1925).—Cereals alone cannot supply all the food requirements of the pig. The value of fish meal as a supplement to a diet of cereals is largely due to the mineral elements it supplies, since similar beneficial results were obtained when an equiv. salt mixt replaced the fish meal.

H. B. LEWIS

Recent advances in the laws of animal nutrition and reproduction. I. Mineral metabolism and the effect of various dietary factors. B. SJOLLEMA. *Z. Tierzücht. Zuchtungsbiol. Tierernähr.* 5, 1-74 (1925).—Review with excellent bibliography under the following heads: mineral metabolism and the influence of various dietary factors; the influence of sunlight on mineral metabolism; the relation between nutrition and reproduction. The relation of Ca and P to lactation and the question of the reproductive vitamin (I) are discussed in particular detail.

H. B. LEWIS

The vitamin contents of canned peas. E. F. KOHMAN. *Canning Age* January, 1926, 48.—Exhaustive tests with canned and home-cooked peas again emphasize the wholesomeness of the factory product. The vitamin contents of canned peas are affected materially by the maturity of the product as well as by the length of the blanch.

THEO. MARKOVITS

The content of fat-like substances in cocks fed on vitamin B-free diets. EIICHIRO KODAMA. *J. Biochem. (Japan)* 5, 185-200 (1925).—The wt. of the individual organs of cocks fed on vitamin B-free diets decreases parallel to the general loss in body wt., though certain organs like spleen and testicle diminish very much more so, while in the case of pancreas and kidney although their absolute wt. decreases their ratio to the total body wt. rather increases. The changes in lecithin, cholesterol and total fatty acid content during this diet vary for each individual organ. Generally, the amt. of lecithin in the organs decreases while that of the cholesterol and total fatty acid increases in the following order: lecithin—kidney, pancreas, heart, liver, spleen, muscle, lung; cholesterol—pancreas, testicle, kidney, heart, lung; fatty acids—testicle, spleen, pancreas, liver, kidney, heart, lung, muscle. The blood lecithin in cocks fed on vitamin B-free diets decreases while the cholesterol and total fatty acid increase as compared to the controls.

Value of albuminous milk as a medicinal food. H. NEUKIRCH. *J. praticiens* 39, 602 (1925); *Bull. soc. hyg. aliment.* 13, 527 (1925).—Albuminous milk consists of butter-milk dild. with 1 vol. of H_2O and 2 vols. of milk and to which casein has been added. The lactose which has been removed by this prepn. is replaced by 5% of dextrin-maltose. N. considers it to be pre-eminently an antifermentative, and the best substitute of human milk as a complete diet.

A. PAPINEAU-COUTURE

Variations in the basal metabolism in infantile denutrition and debility. A. FOUET. *Rev. franç. pédiatrie* 1, 183 (1925); *Bull. soc. hyg. aliment.* 13, 521-2 (1925).—Observations on 22 children, 2 weeks to 16 months old, 8 of whom were congenitally weak and the others nearly all atrophic or athreptic, led to the following conclusions: until the deficiency in wt. (difference between the actual wt. and the wt. of a normal child the same age) reaches 35-38%, the basal metabolism, expressed in cal. per 24 hrs., remains const. allowing for the possible variation of $\pm 15\%$ recently estd. by Benedict. When the deficiency in wt. exceeds this limit there is a sharp drop in basal metabolism. There are thus 2 stages in the slow denutrition of infants: in the first stage, inanition and the cellular reduction which it brings about have not seriously affected the assimilating power of the organism, which, though overworked, still functions normally and can restore normal conditions if a suitable diet is supplied; in the 2nd stage prolonged inanition causes such deep-seated modifications in the physico-chem. equil. of the protoplasm that the power of assimilation can be very considerably reduced, even to such an extent as to prevent all growth. The 1st stage corresponds to what is generally known as 1st and 2nd degree atrophy or hypothyresy, and the 2nd stage to athrepsy. In the former, when a suitable diet is given the organism can assimilate it in sufficient quantity to raise the wt. to that which is normal for its age; while in the 2nd stage extreme caution is required and the qual. and quant. compn. of the diet will depend on the wt. curve and the general reactions of the child. Human milk is essential, and

if it is not tolerated ass's milk should be given. Parenteral introduction of horse serum, or even injection of artificial serum contg. a suitable proportion of amino acids essential to growth and metabolism, may be advisable.

A. PAPINEAU-COUTURE

Thyroid feeding and secondary sex characters in Rhode Island Red chicks. H. B. TORREY AND BENJAMIN HORNING. *Biol. Bull. Marine Biol. Lab.* **49**, 365-74(1925).—When male Rhode Island Red chicks were fed desiccated thyroid in daily doses increasing with the wt. of the birds: (1) Their plumage appeared precociously, but differentiated later than usual, so that at the end of 12 weeks they were feathered like females. (2) Their adult plumage though prevailing male in type exhibited characteristics of form and structure especially in the hackle, saddle, back and shoulder feathers.

L. W. RIGGS

Nutrition of fish by raw and by cooked meat. CHARLES RICHEL, ÖXNER AND J. RICHARD. *Compt. rend.* **181**, 637-9(1925); cf. *Compt. rend.* **180**, 405.—Six specimens of *Cantharus griseus* Cuv. were divided into 2 groups of 3 each and fed raw and cooked meat, resp., for 205 days. The fish were weighed at 10-day intervals and those receiving raw food increased their wt. from 100 to 208, while those receiving cooked food increased their wt. from 100 to 165. The diets were then reversed when the fish that had received cooked meat were fed raw meat and after 20 days of slow growth these fish recovered about the normal rate of growth for fish fed raw meat during the first period. But the fish which had been fed raw meat for 205 days, when fed cooked meat, lost wt. during the first 10 days, gained slightly, then lost wt. again and died on the 58th day. Thus for fish as well as mammals, cooking of meat diminishes its nutritive value.

L. W. RIGGS

Maximum metabolism and the suprarenals. I. GIAJA AND X. CHAHOVITCH. *Compt. rend.* **181**, 885-6(1925); cf. *C. A.* **18**, 1522, 2025.—Rats from which the suprarenals had been removed were not able to adapt their heat production or raise it above the level of basal metabolism. In this case the max. metabolism is lowered to a point to blend with the basal metabolism, while the metabolic quotient becomes unity. The injection of adrenaline into rats from which the suprarenals are removed increases the value of thermal energy output yet without attaining the max. metabolism of the normal rat. The suprarenals appear to play an important and perhaps a fundamental role in the adaptations of heat production.

L. W. RIGGS

Disturbances in calcification in rickets. E. GLANZMANN. *Schweiz. med. Wochenschrift* **55**, 683(1925); *J. Am. Med. Assoc.* **85**, 857.—Rats were kept on McCollum's diet which regularly produces rickets. On these rats was tested the antirachitic action of certain foods. The ratio between the Ca and the inorg. P in the blood is considered the most important factor in the pathogenesis of rickets. Normally this ratio is 1.95 to 1. McCollum's diet does not contain enough P. If the P is increased without the addn. of Ca, or if the Ca is reduced in this diet, rickets does not develop. An excess of Ca in the diet results in a lowering of the inorg. P and in rickets. Vegetables prevent rickets when they contain certain compds. (lecithin, K salts) which correct the disturbed Ca-P ratio in the blood. Consequently it was found that vitamin-free ovo-lecithin or vitamin-poor beef (which reduces the excretion of the phosphoric acid through the intestines) had a very efficient antirachitic action. That overfeeding with cow milk predisposes children to rickets may be explained by the high CaCO_3 content, which lowers the percentage of P in the blood, by the high protein content, which leads to an increased excretion of P, and by the fact that the fats in milk have not the same protective quality against the rachitic factors in milk as the fats in cod-liver oil, for example. The regulation of the blood P is especially dependent on the liver, which discharges continually P-contg. fats into the blood stream, on the pancreatic islands, and on the parathyroids. Insulin decreases the content of P in the blood. Removal of the parathyroids increases the content of P in the blood. Irradiation of rachitic rats results in an increase of P in the blood.

L. W. RIGGS

Chloride-free milk in edema. CARRAYROU. *Bull. Acad. Med. (Paris)* **94**, 943 (1925); *J. Am. Med. Assoc.* **85**, 1997.—Milk freed from chlorides by Puglia's dialyzing method is greatly superior to ordinary milk for persons on a milk diet during treatment for edema and ascites from a failing heart. A small quantity of lactose is added to the milk after dialyzing, to replace that retained by the dialyzer, and the milk is then sterilized.

L. W. RIGGS

The use of high carbohydrate diets in the treatment of diabetes mellitus. W. D. SANSUM, N. R. BLATHERWICK AND RUTH BOWDEN. *J. Am. Med. Assoc.* **86**, 178-81 (1926).—With the use of high carbohydrate diets, insulin-treated patients were kept with the urine sugar free and with a normal blood sugar. The patients were restored to a more nearly normal state of phys. and mental activity, and were freed from the

slightest traces of the acetone type of acidosis. The potatoes, milk and fruits eliminated the acid ash type of acidosis, which, it is believed, has been the cause of the high incidence of blood vessel disease. The diets are more palatable and the patients lose their craving for forbidden foods. A somewhat lower caloric intake apparently is required for full maintenance. The diets are cheaper as they contain no special food and much less of expensive fats.

L. W. RIGGS

Mechanism of antiketogenic action. I. WEISS AND M. ALTAL. *Magyar Orvosi Archivum* 26, 485-96(1925).—The expts. confirm the results of Lundin (cf. C. A. 18, 1684, 3203; 19, 3516) that yeast cells decompose to a slight degree the Na acetoacetate. This ability of yeast cells can be increased by adding to the yeast emulsion fermentable carbohydrates. The same result can be reached by adding the decompn. products of fermentation, such as glycerol, AcH and pyruvic acid. If the AcH produced by fermentation is combined with Na_2SO_3 , the antiketogenic action of the carbohydrate ceases.

L. W. RIGGS

Effect of mineral supplements on reproduction of the albino rat. W. D. SALMON. *Science* 62, 420-1(1925); cf. C. A. 19, 670.—When an improved ration consisting of white corn 30, wheat 30, peanut meal 25, dried meat 12, and cod-liver oil 3 was supplemented with 1% NaCl and 1.5% acid phosphate, reproduction was not more successful than on the acid phosphate ration in the former expts. None of the litters reached the age of weaning. The addn. of 0.5% NaHCO_3 , sufficient to neutralize the excess of H_2SO_4 carried by the acid phosphate, resulted in a marked improvement. Already rats to the 3rd. generation are being raised. A small quantity of H_2SO_4 may limit the growth of the rat in the 2nd. generation even when little or no effect on the growth of the first generation was apparent.

L. W. RIGGS

Ultra-violet light and antirachitic vitamin in the hen egg. J. S. HUGHES, R. W. TITUS AND J. M. MOORE. *Science* 62, 492-3(1925).—In this study eggs from 4 pens of hens receiving varying amts. of ultra-violet light were tested by feeding the eggs to 4 lots of growing chicks. The chicks in lots 1 and 3 which received eggs from hens receiving direct sunshine developed normally as shown by their general appearance and by analysis of their blood and bones. Chicks in lot 2 which were fed eggs from hens that received sunlight filtered through glass and light for 30 min. per day from a Hg-arc lamp developed some rickets, but they were in a much better condition than the chicks in lot 4 which were fed eggs from hens which received no ultra-violet light except that which came through the glass window. A repetition of the expt. confirmed the foregoing results.

L. W. RIGGS

Concentration of the growth-promoting principle obtained from yeast (vitamin B). P. A. LEVENE AND B. J. C. VAN DER HOEVEN. *Science* 62, 594(1925); cf. C. A. 20, 224.—The starting material is the fraction of yeast ext. prepd. according to Osborne and Wakeman. The aq. soln. of this material is brought to p_H 4. Some inert matter settles out. From the soln. the active material is pptd. with alc. The soln. of this material is treated with HNO_3 , and by this treatment a substance is obtained which is active in daily doses of 1.8 mg. The max. loss in active units is 10%. Often such material is prepd. without any loss in active units. The compn. of this material is C 38.2, H 6.0, N 10.3, P 7.6, S 1.46 and amino N none. The S was present mostly in the form of SH groups. From this material the active principle was extd. with silica gel. From the gel by extn. at p_H 9.5 a material was obtained which was active in daily doses of 0.08 mg. and contained about 4% S. The tests were made with the white rat.

L. W. RIGGS

Rickets, ultra-violet light and milk. J. W. GOWEN, J. M. MURRAY, M. E. GOOCH AND F. B. AMES. *Science* 63, 97-8(1926).—Expts. were made by feeding chickens with milk from cows which had been exposed to ultra-violet light and from cows which had not been exposed to ultra-violet light. The chickens were allowed to develop rickets before the feeding expt. began. The results show that more of the substance necessary to cure rickets is absorbed by the cow exposed to ultra-violet light and secreted by her in her milk. The cows prevented from receiving ultra-violet light are not able to secrete this anti-rachitic substance in sufficient quantities to cure or allay the progress of clinical rickets. This suggests that the high incidence of rickets in children during the late winter months is due to their mothers not receiving enough ultra-violet light either during pregnancy or while in lactation, also that cow milk produced especially for baby feeding should be from cows which have had access to ultra-violet light either from the sun or some other source.

L. W. RIGGS

Alimentary kidney disturbance in rabbits. RICHARD V. BODÓ. *Arch. explil. Path. Pharm.* 109, 185-97(1925).—When rabbits are fed on oats deprived of their outer covering a kidney disturbance occurs, accompanied by an albuminuria, a retention

of NaCl, and by hyposthenuria. Degenerative changes in the kidney occur. Acidosis is not responsible for the condition, and whether it is of the nature of an avitaminosis is not certain, although it is definitely not due to a lack of B vitamin. G. H. S.

The assay of cod-liver oil for vitamin A. S. G. WILLIMOTT AND F. WOKES. *Pharm. J.* 115, 718-20(1925).—A detailed discussion of the various factors which influence the accuracy of the physiol. assay of cod-liver oil for vitamin A and their bearing on the assay method of the new U. S. P. Among certain defects of this method are the possible variation of the vitamin content of the diet prescribed; the use of single animals instead of group testing; failure to specify selection of the more steadily growing male rats (*C. A.* 19, 3295); omission of fat in the basal diet and lack of precision in providing for the mineral balance. The Osborne-Mendel and McCollum-Davis salt mixts. given as types to be used differ widely from each other in general compn. and their K/Na, Ca/Mg and Ca/P ratios; hence they cannot yield identical results. Finally, the standard unit as compared with that of Zilva and Miura (cf. *C. A.* 15, 2903) and of Poulsson (*C. A.* 18, 410, 3077) is ten times too low. S. WALDBOTT

Iodine fertilizing and iodine feeding (VON FELLEBERG) 15.

MCLEAN, STAFFORD and FALES, HELEN L.: **Scientific Nutrition in Infancy and Early Childhood.** Philadelphia: Lea & Febiger. 404 pp. \$3.75. Reviewed in *J. Am. Med. Assoc.* 86, 299(1926).

12—PHYSIOLOGY

ANDREW HUNTER

The kidney and amino-acid excretion. E. SCHMITZ AND P. SIWON. *Biochem. Z.* 160, 1-19(1925).—Larger quantities of amino-acid N were excreted in the urine by man when wheat proteins or peas were added to the basic diet than when casein or cod-fish was fed, the N intake being the same in all the expts. Diuresis following excessive H₂O intake caused an increase in amino-acid excretion. Urea, but not NaCl increased the amino-acid output in the urine. F. A. CAJORI

Pigment studies in connection with a case of curly hair. K. KLINKE. *Biochem. Z.* 160, 28-42(1925).—No correlation was found between the color of hair and the total S or cystine-S content of the hair. With the exception of red hair all the S present could be accounted for as cystine S. The tyrosine content of hair more nearly paralleled pigmentation, being higher in red, dark and curly hair than in blond hair. The genetic relation between tyrosine and melanine is suggested. 5.4% O₂ and 2% CO₂ were found in the gas present in the hollow hair cylinders of curly hair. F. A. CAJORI

The content of some materials in the hedgehog during hibernation. E. WEINLAND. *Biochem. Z.* 160, 66-74(1925).—The glycogen, fat, total N and H₂O were detd. in the bodies and livers of hedgehogs at different times during the winter's sleep. A large decrease in glycogen and fat was found as a result of hibernation, with smaller changes in N and H₂O content. F. A. CAJORI

The relative viscosity of the proteins of human blood serum and the method of their determination. W. STARLINGER AND K. HARTL. *Biochem. Z.* 160, 225-36(1925).—The relative and specific viscosity of serum proteins, the relative and specific viscosity-concn. quotients of serum proteins and the viscosity-refraction quotient of serum proteins and of whole serum, after deduction of the H₂O value, were detd. for 39 human serum specimens. F. A. CAJORI

The action of calcium on the acid-base balance of man. GYULA HOLLÓ AND ISTVAN WEISS. *Biochem. Z.* 160, 237-41(1925).—Intravenous injection of 10 cc. of 10% CaCl₂ soln. in patients caused a slight fall in plasma bicarbonate content and rise of alveolar CO₂. Hypertonic NaCl failed to cause the same results. Oral feeding of CaCl₂ and Ca lactate caused a fall in plasma bicarbonate but only slight effect on the alveolar CO₂ and blood acidity. F. A. CAJORI

The carbohydrate of the blood and its behavior in the organism. ALFRED GIGON. *Ergebnisse Physiol.* 24, 196-215(1925).—After the oral administration or subcutaneous injection of glucose or maltose in fasting rabbits, there is a prompt drop in the p_H of the blood, as detd. by the Michaelis method, which returns to normal in 2-4 hrs. Fructose behaves similarly but the fall in p_H is not so rapid, while sucrose, casein and olive oil cause no effect thereon. After the feeding of glucose by mouth, the sugar content of the lymph as well as the portal blood is increased. Glycogenesis does not begin for 3-4 hrs. and reaches the max. 16 hrs. after its introduction. These results are discussed in relation to their effect on protein metabolism, to diabetes and insulin.

H. J. DEUEL, JR.

The temperature of the human skin. F. G. BENEDICT. *Ergebnisse Physiol.* 24, 594-617(1925). H. J. DEUEL, JR.

Water balance. I. Blood dilution after ingesting fluids. HELLMUT MARX. *Klin. Wochschr.* 4, 2339-42(1925).—Ingestion of 50 cc. of H_2O transitorily increases the blood vol. 350-400 cc. Normal conditions are reestablished within 5 hrs. A diuresis need not occur and, when it does, may often appear after the blood vol. has returned to normal. MILTON HANKE

Decalcification of human tooth enamel. J. R. MCCLELLAND. *Dental Cosmos* 68, 127-32(1926).—Human tooth enamel is not decalcified in H-ion concns. between p_H 6.5 and p_H 11.0. Decalcification occurs at p_H 6.0 and less; the speed of decalcification increases with the degree of acidity. JOSEPH S. HEPBURN

Muscular exercise, lactic acid and the supply and utilization of oxygen. XIII. The gaseous exchanges of restricted muscular exercise in man. K. FURUSAWA. *Proc. Roy. Soc. (London)* 99B, 155-66(1926); cf. *C. A.* 19, 2844.—The gaseous metabolism was studied for a type of exercise involving only a limited portion of the musculature of man, by a simple ergometer capable of being worked at any speed by the arms. The amt. of O_2 required to perform a given amt. of work varied with the speed at which the work was done; a marked optimal speed existed. With const. speed and varying load, the O_2 requirement increased as a linear function of the work done; a marked optimal load did not exist. The O_2 intake increased to its max. value far more slowly than in exercise involving most of the musculature, e. g., running; it was still increasing rapidly, in some instances, after 6 min. of exercise. The O_2 -requirement curve diverged at quite low speeds from the O_2 -intake curve. A large O_2 debt was produced by exercise for a few min. with only a small fraction of the total musculature. The excess of lactic acid produced by violent activity of a localized group of muscles may diffuse into the blood, be carried to other parts of the body, especially the resting muscles and liver, and there be removed or converted into glycogen. Exhaustion may occur as a result of complete utilization of the precursor of lactic acid in exercise localized in a small group of muscles. XIV. **The relation in man between the oxygen intake during exercise and the lactic acid content of the muscles.** C. N. H. LONG. *Ibid* 167-72.—In men, as in isolated muscle, the rate of removal of lactic acid, as measured by the O_2 intake, is proportional to the square of the concn. of lactic acid in the fluids which are in contact with the muscle fibers. During the process of recovery in muscle, lactic acid apparently acts as a governor of oxidation. JOSEPH S. HEPBURN

The behavior and action of bile acids in the organism. A. ADLER. *Z. ges. expil. Med.* 46, 371-424(1925).—*In vitro* the addition of increasing amts. of bile salts to blood serum, urine or bile does not cause a continuous lowering of surface tension. This is true also when bile salts are added to colloidal cholesterol solns, while in a lecithin soln. there is a continuous lowering of surface tension. Injection of bile salts in man also brings no regular lowering of surface tension. Methods for demonstrating bile acids, depending on surface tension, are unreliable. Bile acids in addition to an action on surface tension also increase the viscosity of the medium as may be shown on adding bile salts to cholesterol solns., blood serum, bile and urine. The cholesterol or other hydrophilic colloids bind H_2O and adsorb the bile acids in part. Lecithin does not act in this manner. Bile acids when intravenously injected cause a marked increase in secretion of bile. The bilirubin and cholesterol content of the blood decrease and there is an increased excretion of bilirubin in the urine. The excretion of tetrachlorophenolphthalein in the bile is hastened by simultaneous injection of bile acids. Intravenous injection of tetrachlorophenolphthalein causes an increased excretion of bile and when injected in combination with bile acids is an excellent stimulant of biliary secretion. HARRIET F. HOLMES

Insulin and gastric secretion. I. DETRE AND R. SIVÓ. *Z. ges. expil. Med.* 46, 594-9(1925).—Six-unit doses of insulin 3 times a day for 7 days led to an increase of gastric secretion with an increase of free HCl and of total acidity. A single 10-unit dose of insulin usually increased the acidity of the gastric secretion but was occasionally without effect. HARRIET F. HOLMES

Studies on the physiology of sleep. III. Effect of muscular activity, rest and sleep on the urinary excretion of phosphorus. NATHANIEL KLEITMAN. *Am. J. Physiol.* 74, 225-37(1925).—Short periods of muscular work cause retention of P which is excreted after exercise. The excretion of P and total acid is increased during sleep and in the afternoon hrs., while prolonged administration of KBr has no influence. Conclusion: Increased excretion during sleep is due not to mental but to muscular relaxation. MARY JACOBSEN

Studies on the physiology of the liver. XII. Muscle glycogen following total re-

removal of the liver. J. L. BOLLMANN, F. C. MANN AND T. B. MAGATH. *Am. J. Physiol.* **74**, 238-48(1925); cf. *C. A.* **20**, 778.—In hepatectomized dogs intravenously injected glycogen was utilized. The same was true for muscle glycogen to a certain extent only. In spite of the presence of glycogenase in the blood muscle glycogen was not released from the cell rapidly enough to obviate hypoglycemia. The liver must, therefore, be considered as the main source of blood sugar. Glucose injections were followed by immediate recovery, continued injections by regeneration of muscle glycogen.

MARY JACOBSEN

An inhibition in ovulation in the fowl by the intraperitoneal administration of fresh anterior hypophyseal substance. A. T. WALKER. *Am. J. Physiol.* **74**, 249-56(1925).—The inhibition in ovulation is not due to a systemic toxic effect, since the fowl remained in excellent health. It seems to be due to an injurious effect of the excess hormone on the developing ova.

MARY JACOBSEN

Studies on the condition of activity in endocrine glands. XVII. The nervous control of insulin secretion. S. W. BRITTON. *Am. J. Physiol.* **74**, 291-307(1925).—Evidence is brought forth that insulin secretion is controlled by the right vagus nerve. Hypoglycemia of a course similar to that under insulin administration was induced by elec. stimulation of the right vagus in cats under amylal anesthesia in which sugar equil. was previously established by inactivating the left adrenal or severing the left splanchnic. Return to normal or hyperglycemia followed cessation of the stimulus. The circulation through the pancreas is unaffected during the stimulation. If the vessels and nerves of the pancreas are tied stimulation of the vagus does not lower the blood sugar. Exhaustion of glycogen reserve was excluded in the expts. Severing of the hepatic nerves or stimulation of the sympathetic innervation of the pancreas does not influence the blood sugar.

MARY JACOBSEN

Studies on muscular exercise under low barometric pressure. I. The consumption of oxygen and the oxygen debt. E. C. SCHNEIDER AND R. W. CLARK. *Am. J. Physiol.* **74**, 334-53(1925); cf. *C. A.* **19**, 674.—O consumption is reduced at barometric pressures below 410 mm, especially during phys. work. The reduction of O consumption by overload work is also accentuated at low pressure and the deviation from the linear relation between load and O consumed is greater. In the period of recovery the O consumption and CO₂ output are the same as those at normal pressure, showing that the O debt or "acidosis" is not larger at a low pressure.

MARY JACOBSEN

Is prolonged bed rest a prerequisite for the measurement of basal metabolism? F. G. BENEDICT AND ELIZABETH E. CROFT. *Am. J. Physiol.* **74**, 369-80(1925).—The basal metabolism after exercise and exposure to cold with a subsequent rest of 30 min is only slightly higher than that after a night's rest. Since the actual loss of heat does not affect the heat production, the absence of interdependence between these processes may be concluded.

MARY JACOBSEN

The site of formation of bilirubin. F. C. MANN, CHARLES SHEARD, J. L. BOLLMAN AND E. C. BALDES. *Am. J. Physiol.* **74**, 497-510(1925).—Of all large organs and vascular areas examd. spleen and bone marrow contained more bilirubin in the venous than in the arterial blood. These organs are, therefore, considered as the site of bilirubin formation.

MARY JACOBSEN

Studies on the physiological action of light. II. Depression of arterial blood pressure. III. Effects on arterial blood pressure of direct irradiation of blood in vivo. IV. Effects on the blood of the irradiation in vivo. C. I. REED. *Am. J. Physiol.* **74**, 511-7, 518-24, 525-33(1925).—Irradiation of the eyes of an anesthetized dog or of blood in a quartz tube interposed in the carotid artery caused a considerable drop in arterial blood pressure. There was no positive evidence of a depressor substance being liberated into the blood. The blood showed an abs. leucopenia, a lymphopenia but a relative lymphocytosis. Evidently photodynamic effects stimulate biological oxidation.

MARY JACOBSEN

Contributions to the physiology of gastric secretion. VII. An attempt to prove that a humoral mechanism is concerned in gastric secretion by blood transfusion and cross-circulation. A. C. IVY, R. K. S. LIM AND J. I. MCCARTHY. *Am. J. Physiol.* **74**, 616-38(1925); cf. *C. A.* **19**, 2077. **VIII. The proof of a humoral mechanism. A new procedure for the study of gastric physiology.** A. C. IVY AND J. I. FARREL. *Ibid* 639-49; cf. *C. A.* **19**, 2077.—Blood transfusion and cross circulation were found inadequate for the purpose. Expts. with a subcutaneously transplanted gastric pouch proved definitely that a humoral mechanism is concerned in the stimulation of gastric secretion. The hormone hypothesis is neither proved nor disproved. The transplanted pouch has a steady, acid-free or slightly acid continuous secretion. Two to 6 hrs. after a meal or 1 hr. after a histamine or gastrin injection gastric juice contg.

acid is secreted. The glands of the pouch were also stimulated by distending with a balloon, which proves that a local mechanism is, at least partly, involved. M. J.

The source of energy in muscular work. F. FALTA. *Biochem. Z.* **159**, 286-7 (1925).—A reply to Lusk (*C. A.* **19**, 2695). W. D. L.

Investigation of thrombin according to Alexander Schmidt. Blood-clotting. X. H. WOHLISCH. *Biochem. Z.* **159**, 288-97(1925); cf. *C. A.* **19**, 3302.—By comparison of the clotting time of fibrinogen by plasma and serum thrombins both from the same animal, it is shown that the 2 thrombins are not identical. This confirms the statement of Schmidt, but repudiates the work of Stuber and Lee. W. D. L.

The glycogen and cerebroside metabolism of the central nervous system. H. WINTERSTEIN AND ELSE HIRSCHBERG. *Biochem. Z.* **159**, 351-69(1925); cf. *C. A.* **19**, 2694.—From detns. of glycogen and cerebroside sugar present in the nervous system of frogs the following is found: the amt. of glycogen and cerebroside sugar present varies from 1.4% in winter to 0.1% in summer. In salt soln., in presence of O, the carbohydrate content of the nerve material may decrease as much as 50% of its original concn. in 8 hrs. Without O, the decrease is smaller. Elec. stimulation causes an increase in the glycogen content. Insulin markedly increases the glycogen and cerebroside levels. Greater effects can be noted with addn. of sugar or by stimulation in the presence of insulin, *e. g.*, glycogen increases 100 and cerebroside sugar 200% of the normal values. The results with strychnine are less definite. W. D. L.

Changes of metabolism with irradiation. I. Changes of the potassium and calcium content of blood with irradiation. L. PINCUSSEN. *Biochem. Z.* **161**, 61-6(1925).—After irradiation, the K content of serum from man decreases about 10%, unless a sensitizer such as anthracene is used, when the decrease is less. Ca, on the other hand, decreases only about 5%. The ratio K/Ca, therefore, decreases. **II. Influence of sunlight upon mineral metabolism.** *Ibid* 67-70.—The excretion by rabbits of K, Ca and Mg in the urine varies with the intensity of light in which they are kept, *e. g.*, upon a diet of carrots the K/Ca ratios in the dark, reflected light and sunlight are 19, 25.3 and 33.5, resp., while the Ca/Mg ratios are 1.73, 0.57, 0.62. A similar variation in these ratios is found upon a diet of oats. W. D. L.

Changes of the enzyme content of blood. I. L. PINCUSSEN. The variability of nuclease and lipase. E. COELHO. *Biochem. Z.* **161**, 71-9(1925).—A study is made of the effect of injected drugs, such as adrenaline and pilocarpine and of salts, such as KCl and CaCl₂, upon the amt. of nuclease and lipase in rabbit blood. The changes are not well defined. W. D. L.

Spleen and metabolism. I. Influence of splenectomy upon the excretion of nitrogen and creatinine. A. PALLADIN AND LYDIA PALLADIN. *Biochem. Z.* **161**, 104-13 (1925).—Contrary to the findings of other investigators, there is no increased excretion of N after splenectomy, but after 4 days a slight but progressive decrease was apparent, which continued for 2 or 3 months. But the excretion of creatinine is increased so that the creatinine coeff. becomes high, *e. g.*, from 18.6 to 27.0 in a month. W. D. L.

Influence of artificial venous obstruction upon the weight, diameter and volume of red blood corpuscles. L. PEZZOTTI. *Biochem. Z.* **161**, 114-20(1925).—Artificial venous obstruction does not uniformly influence the size or wt. of corpuscles. W. D. L.

The autolytic decomposition of organic phosphorus compounds in tissues. P. GYÖRGY. *Biochem. Z.* **161**, 157-77(1925).—The hydrolysis of the org. PO₄ compds. which occur in tissues is called autolysis. The conditions under which hydrolysis is favored or prevented are described for blood, liver, kidney, brain and muscle. In the case of blood, the decompn. is enzymic, is prevented by NaF or Na₂C₂O₄ and is favored by hemolysis, although saponin soon slows down the reaction. Both acids and alkali retard the reaction. Much of the urine PO₄ is due to the hydrolysis of these org. PO₄ compds. by the kidney. W. D. L.

The reducing and iodine-absorbing power of urine. I. The normals. H. K. BARRENSCHEEN AND L. POPPER. *Biochem. Z.* **161**, 210-8(1925).—There does not occur a reducing substance (the U substance of Moor, *C. A.* **19**, 2215) in normal urine other than the coloring materials present. When acidified with AcOH, the I-absorbing power of urine is decreased 9 to 29%, but the reducing power toward FeFe(CN)₆ remains unchanged. The decrease of absorption of I goes parallel with the amt. of urobilinogen pptd. and is probably due to this substance. W. D. L.

The role of the phosphates in carbohydrate metabolism in skeletal muscle. FLOR-ENCE BEATTIE AND T. H. MILROY. *J. Physiol.* **60**, 379-401(1925).—Normal mammalian muscle *in vitro* treated with NaF can synthesize 80 to 90% of the preëxisting free phosphate with the glycogen present to form *hexosephosphate*. The synthesis is always

accompanied by a greater consumption of glycogen than is required for esterification, but the lactic acid production is always checked or there may be a disappearance of the acid. The beneficial effect of added glycogen was more evident after the addition of more phosphate. The muscle of insulin-treated cats behaved in much the same way as normal muscle except there seemed to be a tendency in the insulinized muscle to hold up glycogen. In the muscle of adrenalized cats the synthesis under the influence of NaF was much diminished. Lactic acid production always accompanied the synthesis even when the glycogen that disappeared was sufficient to account for the synthesis. Glycogen addition to adrenalized muscle improved the synthesis slightly or not at all. Adrenalized muscle always showed an initial low glycogen content and a much lower lactic acid percentage than normal or insulinized muscle. The muscle of insulin-treated adrenalized animals, compared with the untreated, showed a marked improvement in the synthesis of both the intrinsic and the added phosphate although it was seldom so good as in the normal or insulin normal cases. J. F. I.

The effect of thyroid feeding on sugar tolerance. II. P. MARKS. *J. Physiol.* 60, 402-10(1925).—The thyroid-fed rabbit, whose liver still contains glycogen, shows a secondary hyperglucemia following the injection of glucose or a small dose of insulin. When the liver is depleted of glycogen, a small dose of insulin, or an injection of glucose, produces a fatal hypoglucemia in the thyroid-fed animal. The maintenance of the normal blood sugar level seems to involve a no. of opposing factors. The liver compensates for a fall in blood sugar by an accelerated output of glucose; the pancreas compensates for a rise by an accelerated output of insulin. The thyroid hormone sensitizes the liver to influences promoting glycogenolysis. Excessive thyroid feeding may lead to hypertrophy of the islet tissue of the pancreas, accompanied by atrophic changes in the pituitary. All these factors taken together may account for the results obtained. J. F. LYMAN

Physiology of the glands. LXXXIII. LEON ASHER. Demonstration of the formation of carbohydrate from fat and its dependence upon the liver. V. CALVO-CRIADO. *Biochem. Z.* 164, 76-96(1925).—Rats were made carbohydrate-free through preliminary dietary prepn. with the use of peptone, then by more or less prolonged treatment with thyroid substance and phlorhizin injections, all of which prevented the deposition of glycogen and caused a continuous elimination of sugar. The addition of fat to the food called forth either immediately or soon afterwards a considerable increase in the urinary output of sugar. On the days of max. sugar excretion the N elimination remained unchanged or diminished somewhat so that the D/N ratio reached max. values. A very small addition of sucrose to the diet increased the formation of sugar from fat markedly, which is explained as being due to an improvement of the synthetic function of the liver by the extra sugar in the diet. LXXXIV. The respiratory exchange during work in its relation to glands of internal secretion. G. M. CURTIS. *Ibid* 97-109.—The performance of the same amt. of work (running 1 km. per hr.) causes in the adult male rat an increase of 81% in the CO₂ production and of 64% in the O consumption. The increased respiratory quotient leads to the conclusion that carbohydrates furnish a considerable part of the energy necessary for the work. S. MORGLIS

Studies of intermediary carbohydrate metabolism. X. Contribution to the problem of glucolysis. TH. BRUGSCH AND H. HORSTERS. *Biochem. Z.* 164, 191-8 (1925); cf. C. A. 20, 226.—In the dry liver or muscle substance there is no evidence of the presence of a glucolytic enzyme. The muscle and liver glycogenase are not inhibited by insulin. XI. The hexosediphosphatase of muscle and liver and its cleavage product, the monohexosephosphoric acid. TH. BRUGSCH, M. COHEN AND H. HORSTERS. *Ibid* 199-206.—The dry substance of muscle and liver from rabbit or dog contains hexosediphosphatase, which changes the hexosediphosphoric acid into a dextrorotatory hexosemonophosphoric acid. The latter gives a strong Seliwanoff reaction. The fresh muscle, unlike the dry substance, can split hexosediphosphoric acid into H₂PO₄ and *d*-fructose, then into monohexosephosphoric acid, and finally into hexose and lactic acid. Hence the intermediate sugars of liver and muscle must in part represent a mixt. of hexosediphosphoric and hexosemonophosphoric acids. The α - and β -hexosediphosphatases are not identical, since dry muscle contains only the β , while fresh muscle contains both enzymes. XII. The effect of insulin on the respiration of muscle and liver. TH. BRUGSCH, H. HORSTERS AND J. VORSCHÜTZ. *Ibid* 207-46.—The muscle or liver was taken from animals immediately after they were killed and freed of blood. The substance was at once weighed and broken up in a mortar, then washed about 15 min. once or several times with distd. water. The material was now sepd. from the water by filtration and suspended in Ringer soln. without NaHCO₃.

Two 30 cc portions were then placed in 300 cc. flasks, one of which also received a definite quantity of insulin. A 3rd flask contg. unwashed tissue suspended in Ringer soln. but without insulin served as control. All 3 flasks were shaken 50 min. in a thermostat at 40° and the air was analyzed for CO₂ and O₂. It was found that insulin has a stimulating influence on the respiration of washed muscle which, however, may also become inhibitory. The expts. give no clue as to the conditions which one or the other effect. It was also found that the boiled out juice of muscle depresses the respiration of muscle tissue while the boiled out juice from yeast or liver and especially thyroxin augment the respiration. Expts. were also performed to det. the rate of O₂ consumption of muscle substance, a modified Barcroft app. was used for this purpose. In large, unphysiol. quantity insulin causes an increased O₂ intake of both washed and unwashed muscle tissue. In smaller doses the insulin either does not act at all, or when active may produce either a stimulating or depressing effect. In fasting condition and especially in the hypoglycemic complex, insulin acts depressingly on the muscle respiration, which is thought to be due to the induced carbohydrate synthesis.

XIII. Experiments on the formation of lactic acid in the liver from acetic, tartaric, malonic and succinic acids. TH. BRUGSCH, H. HORSTERS AND S. NARITA. *Ibid* 247-56.—Perfusion expts. on livers show that acetic acid does not form lactic acid either in the livers from normal or diabetic (depancreatized) dogs, while malonic, tartaric and succinic acids do give rise to lactic acid.

XIV. Effect of insulin on the muscle dehydrodrases. *Ibid* 257-70.—Expts. are carried out with muscle tissue suspension by Thunberg's methylene blue method. The washed guinea pig muscle has no effect on the methylene blue unless a small amt. of Na succinate is added to it; then the dehydrodrase manifests itself through the discoloration of the dye. There is a similar result when lactic acid or *d*-fructosediphosphoric acid is added. The addition to washed muscle of insulin also exerts a definite dehydrodrase action, so that it may be definitely regarded as the activator of the lactic acid dehydrodrase of muscle. Muscle from animals treated with insulin shows the presence of a dehydrodrase effect on galactose, glucose, *d*-fructose, *d*-fructosediphosphoric acid and benzaldehyde. S. MORGULIS

The nature of the so-called serum antipepsin. W. MOZOLOWSKI AND H. HILAROWICZ. *Biochem. Z.* 164, 295-311(1925).—The inhibitory action which blood serum has on a peptic digestion in acid medium and which has been regarded as being due to a binding of pepsin by an antipepsin present in serum is shown to be entirely caused by a change in the H-ion concn. resulting from the addn. of the serum. S. M.

Studies on the injection of follicular fluid. J. WATRIN. *Compt. rend. soc. biol.* 93, 772-3(1925).—Follicular fluid produces remarkable vaso-dilator effects. This may even cause rupture of the vessels of the myometrium. S. MORGULIS

Studies on the diffusion of urea through the peritoneum. MARCELI LANDSBERGER AND HENRYK GNOINSKI. *Compt. rend. soc. biol.* 93, 787-8(1925).—Ringer soln. is allowed to flow through the peritoneal cavity of rabbits. The outflowing soln. contains the various nitrogenous and non-nitrogenous components of the blood which are removed by diffusion. In rabbits made uremic this artificial ascitic fluid contains large amts. of urea (352 and 680 mg. in 2 expts.). S. MORGULIS

Cholesterol in the cerebrospinal fluid during pregnancy and delivery. M. GAROFEANU AND N. LAZAR. *Compt. rend. soc. biol.* 93, 791-2(1925).—There is no cholesterol in the cerebrospinal fluid in the normal condition, during pregnancy or delivery. S. MORGULIS

Cholesterolemia in pellagrins. I. ORNSTEIN. *Compt. rend. soc. biol.* 93, 793-5(1925).—A hypercholesterolemia has been found in pellagrins which is interpreted as a sign of disintegrative process in tissues comparable to that observed in aged people. S. MORGULIS

Properties of the active substances of the right auricles of the heart. JEAN DE MOOR AND PIERRE RYLAKT. *Compt. rend. soc. biol.* 93, 814-6(1925).—An aq. ext. of the right auricles from hearts of several species used 4-5 hrs. after trituration, or a 4-hr. alc. ext. from material previously treated for 2 hrs. with Me₂CO, causes rhythmic reaction of the left auricle, which starts immediately, lasts for a long time and terminates suddenly. The H₂O ext. heated for 20 min. at 53° retains its activity and produces more regular results than the unheated. Heated to 60° it loses its ability to produce rhythmic contraction but it still sensitizes the auricle to adrenaline, while heating at 70° makes it entirely inactive. The alc. ext. gives less const. results. S. M.

The influence of fats on tar cancer in mice. J. LECLOUX. *Compt. rend. soc. biol.* 93, 832-3(1925); cf. *C. A.* 19, 1308.—Fe or Co compds. of oleic and stearic acids in paraffin-oil suspension were injected intraperitoneally into mice with tar tumors. In all mice thus treated there appeared a softening of the tumor within 15-25 days fol

lowing the injection. The paraffin oil alone did not produce the same effect. **Study of the mechanism of the action of fats on the development of tumors in mice.** *Ibid* 834-5(1925). S. MORGULIS

Reflex secretion of adrenaline. B. A. HOUSSAY AND E. A. MOLINELLI. *Compt. rend. soc. biol.* **93**, 881-3(1925).—The enervated heart of dogs shows regular acceleration under the influence of adrenaline injections. The acceleration varies from 4 to 60 beats per min., the av. being 30, which can be evoked by a rapid intravenous injection of 0.007 mg. of adrenaline. The heart reaction is a good measure of the adrenaline quantity. S. MORGULIS

Adrenaline discharge caused by muscular activity. B. A. HOUSSAY AND E. A. MOLINELLI. *Compt. rend. soc. biol.* **93**, 884-5(1925).—The acceleration of the enervated heart depends upon adrenaline secretion provoked by the products of muscle activity. This effect is exerted upon the adrenaline secretory center because it disappears after both large splanchnics are cut. During the first 15 sec. there is a slight diminution in the rate of the heart beat which is not, however, to be attributed to inhibition of adrenaline secretion as it also occurs and even in a more marked degree when the adrenals are absent. S. MORGULIS

Synthesis and destruction of phosphatides in the animal organism. KOKICHI KOIZUMI. *J. Biochem. (Japan)* **5**, 171-84(1925).—Exptl. procedures: The lymph is collected from the thoracic duct by means of a special metal canula which permits the operator to introduce $MgSO_4$ while drawing off the lymph and thus prevent its clotting. The amt. of added $MgSO_4$ is carefully calibrated and can be deducted from the mixed lymph collected. The fat fed to the dogs was usually 50-100 g. of liver oil which was previously thoroughly emulsified with 2 g. $NaHCO_3$ by rubbing in a mortar with enough water to give a final vol. of 350 cc. This emulsified fat was administered to the dogs in small quantities. The lymph was collected both before and after the fat feeding. The total fat and phosphatide content was detd. by extn. in a Soxhlet app. with alc., Et_2O and after dissolving in petroleum ether the material was filtered, evapd. and weighed. The lecithin portion was calcd. from the P detn. Also the total N was detd. by the micro-Kjeldahl method, and the choline by the method of Maclean. Five to eight hrs. after the feeding the dogs were killed and the fat and lecithin content of various organs and tissues also detd. The I no. was detd. for both the fatty acids fed and for the organs. After a preliminary extn. for 4-5 hrs. at 50° with abs. alc. completely to dehydrate the material, then with Et_2O , the combined exts. were filtered, evapd. and the lecithin Cd salt was prepd. on which the I detn. was made according to Hubl's method. By this direct study of the lymph K showed that after feeding of fat there was an increase in the phosphatide content as well as a synthesis of phosphatide in the intestinal mucosa. The phosphatide increases in the lymph parallel to the increase in fat, and this appears about 2-3 hrs. after the feeding, but the phosphatide does not increase quite so much as the fat but remains at a high level for a longer period. According to the N, P and choline the increase of lipid in the lymph must be due to a monoaminophosphatide similar to lecithin. The substance differs, however, from lecithin in that it fails to form a ppt. with alc. $CdCl_2$ soln. or on addn. of acetone. The feeding of fat seems also associated with an increased fat content of the organs, especially the liver, and the same is true for the lecithin content. Judging by the I no. of the liver lecithin after fat feeding this organ is regarded as the principal lecithin-forming organ. Three to five hrs. after the injection of lecithin into a vein there is a definite increase of lecithin, fat and of P in the liver. The latter is supposed to be derived from the inorg. P of the serum of the blood. There is thus a building of fat from fatty acids and glycerol after the introduction of lecithin, and there is also evidence of an inter-conversion of fat and lecithin in the liver. S. MORGULIS

Investigations on the biological chemistry of the living cell as a basis for the treatment of arteriosclerosis. H. PÉRICAUD. *Vie médicale* **6**, 1433(1925); *Bull. soc. hyg. aliment.* **13**, 520(1925).—Mayer's and Schaeffer's numerous analyses justify the conclusion that the amts. of cholesterol and phosphatides in a given cellular species are practically const. and that the lipocytic coeff. cholesterol/lipoid-P is characteristic of each organ. Arteriosclerosis is admitted to be due to cholesterol deposits in the walls of the vessels resulting from intoxications or infections, and $CaCO_3$ is subsequently deposited on the cholesterol. KI, long recommended for the treatment of arteriosclerosis, would appear to act rather as a sclerosing agent. A more rational therapeutic treatment would be to distribute freely phosphatides or colloidal phosphorous lipoids. Expts. carried out by P. on animals confirmed his hypothesis. A. P.-C.

The activity of an isolated turtle heart irrigated with Ringer solutions of varying hydrogen-ion concentration. HENRI FREDERICQ. *Bull. sci. acad. roy. Belg.* [5], **11**,

308-22(1925).—The activity (chronaxie) of a turtle heart irrigated with NaCl solns. of varying H-ion concn., *i. e.*, the time of contractile response to the exciting elec. impulse, increases with increasing H-ion concn. and *vice versa*. Expts. are described in detail and a bibliography of 30 references is appended. W. B. PLUMMER

Azotemia during mountain sickness. H. GUILLEMARD. *Compt. rend.* 181, 628-9 (1925).—During an ascension of Mt. Blanc, samples of blood were taken from G. and from his 14-year-old son at different elevations, and the N was detd. by standard methods. The results in mg. of N per l. blood of G. from Chamonix to Alger ranged from 306 to 358, at Grand Mulets (3050 m.) 345, 4 samples during 3 days at Vallot Observatory (4395 m.) 471, 483, 503 and 496, resp. For the son the figures were: at Alger 297, Grand Mulets 291, and at the Observatory 441, 472 and 449, resp.

L. W. RIGGS

The behavior of blood platelets in new-born and quite young infants. I. FARNOS. *Magyar Orvosi Archivum* 26, 513-8(1925).—The no. of blood platelets increase up to 14-21 days. With jaundice the increase is greater, and there is a proportional decrease of red blood cells. With infections the no. of platelets decrease. L. W. RIGGS

Another outlook on the chemical regulation of respiration. ROBERT GSELL. *Science* 63, 58-62(1926); cf. *C. A.* 18, 291.—The theory of respiratory control is summarized as follows: Changes in the H-ion concn. of the respiratory center rather than of the blood constitute the prime factor in respiratory control. Since the supply of O dects. the abs. and relative amts of lactic acid and CO₂ formed in living tissues and since it controls the efficiency of transport and elimination of acid, it constitutes the normal and indirect regulator of pulmonary ventilation. The effects of lactic acid and CO₂ are additive. They are exerted indirectly by way of the blood from the tissues, and more directly through their formation in the respiratory center itself. Diminished oxidation in the respiratory center leads to an accumulation there of the relatively poorly diffusible lactic acid in a relatively poorly buffered cytoplasm and lymph, no longer fully protected by the potential alkyl. of the blood, the dual function being disturbed by the diminution in the reduction of hemoglobin and the liberation of alkali as it passes through the center. By virtue of its own metabolism and its extreme sensitivity to minute changes in its own H-ion concn. the respiratory center is sensitive to minute changes in its own oxidations and, therefore, to changes in the tension of O in the arterial blood. The capacity of the center to respond to changes in the arterial CO₂ tension consequent on fluctuations in the general metabolism, however, must also be a factor. Also in *Physiol. Rev.* 5, 551-95(1925). L. W. RIGGS

Transformation of glycogen. LUNDGAARD AND HOLBØLL. *Ugeskrift for Læger* 87, 881(1925); *J. Am. Med. Assoc.* 85, 2060; cf. *C. A.* 20, 440.—The glycogen in fresh and finely chopped liver is split into α - β -glucose. Insulin does not effect this cleavage. It is assumed that glycogen in the living subject undergoes the same transformation. The carbohydrates under the action of insulin are partly oxidized and partly deposited as glycogen. When the insulin is no longer in the blood, the deposits of glycogen are split into glucose, which explains the higher sugar content of the blood in the morning. The question is raised: Is the new glucose (called "ny glucose") with a lower sp. rotatory power an intermediate link in the production and deposition of glycogen? **Action of liver tissue and insulin on glucose.** *Ibid* *Ugeskrift for Læger* 87, 905; *J. Am. Med. Assoc.* 85, 2060.—From this later study it is concluded that the liver serves in carbohydrate metabolism as a storage place for glucose in the form of glycogen and has no direct importance for the metabolism of glucose in the organism. Contrary to muscle tissue, liver tissue is not able to form new glucose out of α - β -glucose under the influence of insulin. L. W. RIGGS

G—PATHOLOGY

H. GIDEON WELLS

The secretion antecedents and mitochondria in pathologic thyroids. J. A. KEY. *Arch. Surg.* 11, 254-303(1925).—Chromophil granules and chromophobe vacuoles can be demonstrated in cells of normal and of pathologic thyroids. It is believed that they are the secretion antecedents and that the intracellular colloid is a mixt. of the two. The vacuoles contain the active principle of the gland. No abnormal secretory antecedents were found in toxic adenomas or exophthalmic goiters. Mitochondria are not concerned with secretion in the thyroid. J. T. MYERS

Anaerobic life of tumor tissue. Y. OKAMOTO. *Biochem. Z.* 160, 52-65(1925).—By measuring CO₂ production, it was demonstrated that Flexner-Jobling rat carcinoma, Jensen rat sarcoma and Rous hen sarcoma can live under anaerobic conditions. F. A. CAJORI

The recognition of enzyme processes determined by immunization. III. E. KUPELWIESER AND E. NAVRATIL. *Biochem. Z.* **160**, 75-87(1925); cf. *C. A.* **19**, 342.—In not a single expt. could a specific proteolytic enzyme action be detected in activated horse serum. Refractometric measurements were used to detect proteolysis. **IV.** E. KUPELWIESER AND I. WILHEIM. *Ibid* 88-100.—The negative results reported in the previous paper cannot be ascribed to errors of the refractometric method as a means of detecting proteolysis. F. A. CAJORI

Reversible hemolysis. L. BOGENDÖRFER AND B. HALLE. *Biochem. Z.* **160**, 199-209(1925).—Under suitable conditions reversible hemolysis was observed in every blood studied and with hemoglobin and stroma from different animal species. The phenomenon is ascribed to adsorption of hemoglobin on the stroma. F. A. CAJORI

Blood sugar studies during pregnancy. HANS GUGGISBERG. *Ergebnisse Physiol.* **24**, 718-27(1925). H. J. DEUEL, JR.

Blood sugar and carcinoma. F. SILBERSTEIN, JOHANN FREUD AND TIBOR RÉVÉSZ. *Klin. Wochschr.* **4**, 2252(1925).—The immediate effect of insulin on the blood sugar in carcinomatous patients is normal; the blood sugar is reduced. Continued injection, however, lead to an elevation of the fasting blood sugar value. Thus, in one case, the fasting value was 0.139 g. % before treatment and 0.212 g. % after 10 days of treatment. The increased reducing power of the blood may be due to something other than glucose. MILTON HANKE

Activation of insulin by protein. II. FERDINAND BERTRAM. *Klin. Wochschr.* **4**, 2285-8(1925); cf. *C. A.* **19**, 2532.—A mixt. of insulin with a protein soln., either animal or vegetable, is more active, when injected intramuscularly, than the insulin itself. As activator, the person's own serum is most effective, the action being intensified 3 to 4 times. Whole blood is far less effective than serum. The intensification factors of a number of proteins are as follows. Diabetic serum, 2+, human serum, caseosan, albumin and globulin, 2, novoprotein < 2. A ppt. is obtained when insulin is mixed with certain of the protein solns. which is greatest with caseosan and least with serum. The ppt. adsorbs some of the insulin. For a max. effect, the mixt. should be injected. The action of insulin is not intensified when the insulin-protein mixt. is injected intravenously. The intensification is, therefore, not due to a new compd. formation. It must be associated with a modified *absorption* of the insulin with, perhaps, a decreased rate of destruction. MILTON HANKE

The significance of the atoxyl-resistant lipase in the serum of patients afflicted with diseases of the pancreas or with pernicious anemia. HANS SIMON. *Klin. Wochschr.* **4**, 2295-8(1925).—Demonstration of an atoxyl-resistant lipase in the serum by the method of Rona (*C. A.* **17**, 1077; **18**, 1530) is a fairly certain proof that the pancreas is diseased. The method is rapid and so delicate that the pancreatic disturbance can be diagnosed before it has progressed very far. Pernicious anemia is associated with an injury to the pancreas. Whether or not the involvement of the pancreas is the cause of, or is caused by the anemia, could not be detd. MILTON HANKE

Adrenaline blood-pressure curves in essential hypertension. ISTVAN HETÉNYI AND ISTVAN SÜMEGI. *Klin. Wochschr.* **4**, 2298-303(1925).—Essential hypertension is characterized by an unusual reaction toward adrenaline. The blood pressure rises rapidly and then, within an hour, drops below the initial value only to rise again almost to its highest value. This is followed by another drop below normal, another, though less elevated rise and a final settling down to its initial value. Essential hypertensives are hypersensitive to adrenaline. MILTON HANKE

Transfer of endogenous and exogenous dyes from the mother's blood into the liquor amnii in a case of acute yellow atrophy of the liver. W. JÜLICH. *Klin. Wochschr.* **4**, 2337-9(1925).—One case is described. The woman aborted after the administration of tetrachlorophenolphthalein. The dye was found in the blood of the umbilical cord and in the amniotic fluid. Bilirubin was also present in the amniotic fluid. M. H.

Resistance of the skin during pregnancy. HANS HINSELMANN. *Klin. Wochschr.* **4**, 2346(1925).—Pregnancy reduces the resistance of the skin to irritants such as formalin and HgCl₂. MILTON HANKE

A chemical diagnosis of malignant tumors. H. J. FUCHS. *Klin. Wochschr.* **4**, 2350(1925).—With 1 cc. of the serum from the suspected case of malignancy mix 2 mg. finely powdered, human blood fibrin and incubate for 24 hrs. at 40° under sterile conditions. Remove the proteins and analyze the filtrate for N by the micro-Kjeldahl method. Non-malignant serum does not digest human fibrin; Kjeldahl N is absent in the deproteinated filtrate. Malignant serum does digest fibrin; Kjeldahl N is easily demonstrable. MILTON HANKE

The effect of injected protein upon the metabolism of alkaptonurics. I. H.

BAAR AND P. FREUD. *Klin. Wochschr.* **4**, 2388-9(1925).—Protein, when injected into a child with alkaptonuria, temporarily reduces the excretion of homogentisic acid. Horse serum, beef serum and milk were used. MILTON HANKE

Skin capillary and secretion observations in diabetes mellitus. E. JÜRGENSEN AND K. H. NOORDEN. *Klin. Wochschr.* **4**, 2395-6(1925).—The subcutaneous administration of insulin leads to a dilation of the skin capillaries with a concomitant increased rate of blood flow through these capillaries. The early stages of diabetes are associated with an increased nervous irritability so that a given stimulus produces an excessive secretion of sweat. The later stages of the disease are characterized by a decreased irritability. MILTON HANKE

The surface tension of transudates and exudates. D. ADLERSBERG AND O. STERNBERG. *Klin. Wochschr.* **4**, 2398-9(1925).—Transudates have a surface tension above 870 and exudates have a surface tension below 870 ($H_2O = 1000$) MILTON HANKE

Differential diagnosis of diseases of the hematopoietic system. M. S. REUBEN. *Arch. Pediatrics* **43**, 15-49(1926) — An elaborate discussion. Special attention is paid to the chem. and other lab. tests. JOSEPH S. HEPBURN

Chemical analysis of teeth affected by dental caries and by pyorrhea alveolaris. J. L. ULRICH. *Dental Cosmos* **67**, 1204-8(1925).—In carious teeth and in teeth surrounded by pyorrhea alveolaris, the Ca content is less and the Mg content is greater than in sound teeth. The change in compn. usually is more pronounced in pyorrhea than in caries, and is due to necrosis and inflammation. JOSEPH S. HEPBURN

Relation of the hematopoietic system to the development of bone. ANDREA DE BOSÁNYI. *Dental Cosmos* **68**, 14-6(1926) —In rickets, the bone marrow is characterized by dysfunction in both osteogenesis and hematopoiesis; a const. decrease occurs in the hemoglobin content of the blood of rachitic rats. Addition of 4 to 5% of hemoglobin to a rachitic diet both prevents and cures rickets. Since the antirachitic action of hemoglobin is exerted in the absence of light, it is not due to sensitization to light; it is not a property of the hematin group. Apparently bone marrow produces hemoglobin and another protein; both proteins have a role in bone formation. J. S. H

The degree of acidity of the vaginal secretion. B. BEHRENS AND H. NAUJAK. *Z. ges. expit. Med.* **47**, 178-82(1925) —In detn. of the degree of acidity of the vaginal secretion, methods using indicators such as γ -di-nitrophenol or p -nitrophenol are not reliable on account of the presence in the vaginal secretion of proteins which form colored salts with the indicators. A potentiometric method, therefore, was used in detg. the acidity of the vaginal secretion in 50 women. The only relationship that could be made out confirmed the work of Schroeder (*Zentr. Gynäkol.* No. **38** (1921)) of 3 grades of acidity corresponding to the bacterial flora present. The normal vaginal secretion with vaginal bacilli predominating gave p_H values 3.86-4.45; when there was an admixture of cocci the p_H value was 4.6-5.34 while p_H values of 4.9-6.04 accompanied large numbers of cocci, particularly streptococci. HARRIET F. HOLMES

Chlorine metabolism in disturbances of gastric secretion. G. HOLLER. *Wiener Arch. inn. Med.* **11**, 251-66(1925).—The normal Cl and H_2O metabolism is altered in cases of ulcer of the stomach and duodenum. In general, in cases of duodenal ulcer there is a high acidity of the stomach contents with the elimination of much H_2O and chlorides. Chronic appendicitis with hyperchlorhydria acts like duodenal ulcer. In ulcer of the stomach there is a low acidity with the elimination of little H_2O but an abundance of chlorides. In carcinoma of the stomach there is usually a low elimination of H_2O and chlorides except that when there is a high chloride content of the stomach which sometimes accompanies an acidity, there is an abundant elimination of H_2O and Cl. HARRIET F. HOLMES

The reduction of idiomuscular irritability. The action of glucose and insulin on muscular activity. V. KOLLERT AND E. JOHN. *Wiener Arch. inn. Med.* **11**, 267-80(1925).—Idiomuscular irritability, as indicated by the occurrence of a local muscular contraction on mild percussion, occurs in fatigue or cachexia. The condition is improved by intravenous injection of glucose and there is still greater improvement if insulin is added, though insulin has no effect by itself. Levulose is less efficient than glucose, while an intravenous injection of a soln. contg. NaH_2PO_4 and Na_2HPO_4 is less efficient than glucose but more efficient than levulose. Glucose had little effect on the muscles of cachectic carcinomatous patients, perhaps because the tumor tissue readily absorbed the glucose. It is probable that the idiomuscular irritability indicates a disturbance of the carbohydrate metabolism of the muscles. HARRIET F. HOLMES

The influence of the spleen on iron metabolism. F. LAUDA. *Wiener Arch. inn. Med.* **11**, 292-310(1925).—Splenectomy in rats does not alter the Fe content of the

different organs as detd. by histochemical study. Siderosis of the organs follows splenectomy only in infected rats with a hemolytic anemia. HARRIET F. HOLMES

The pathology of respiratory metabolism. III. The specific dynamic action of carbohydrates and its dependence on the regulation of the intermediary water metabolism. H. POLLITZER AND E. STOLZ. *Wiener Arch. inn. Med.* 11, 319-56(1925); cf. *C. A.* 19, 2699.—Great variations in basal metabolism were noted in different individuals after the intake of carbohydrates. In the same individual bread and dextrose as the source of carbohydrates had quite different effects. Dextrose might be expected to increase basal metabolism more than bread but not infrequently dextrose caused a decrease of basal metabolism. This was particularly marked in some pathological conditions, as icterus catarrhalis, and seemed to be related to the water-regulatory function of the liver. Under the influence of carbohydrates two antagonistic stimuli are brought in play, one stimulating metabolism through increased oxidation and the other depressing metabolism through the water-regulatory function of the liver. There seems to be no specific dynamic action of food but the intake of food starts into action the complicated mechanism regulating the constancy of basal metabolism, of water metabolism and of temp. HARRIET F. HOLMES

The different behavior of so-called blood group agglutinins in native blood plasma and blood serum. W. STARLINGER AND U. STRASSER. *Wiener Arch. inn. Med.* 11, 399-404(1925).—Native plasma from subjects of group II agglutinated corpuscles from groups III and I less strongly than serum from the same subject. Native plasma from subjects of group III agglutinated corpuscles from groups II and I more strongly than the serum from the same subject. The next most frequent type was in subjects of group II where the plasma did not agglutinate any corpuscles while the serum agglutinated the corpuscles from groups III and I slightly. HARRIET F. HOLMES

The effect of the absence of kidney function on cholesterol metabolism. Experimental uremia. W. N. NEKLUDOW. *Z. ges. expil. Med.* 47, 70-6(1925).—In cats extirpation of the kidneys or tying off of the ureters is followed by an increase in cholesterol content of the blood, which increases progressively until the death of the animal. This cholesterolemia is independent of the adrenals and seems due to an increased formation of protein cleavage products which are accumulated in the organism when not eliminated through the kidneys. Uremic symptoms were noted. The absence of some of the symptoms when the kidney is extirpated indicate that the kidney itself produces various toxic substances. HARRIET F. HOLMES

Insulin and glucuronic acid. R. HURTHLE. *Z. ges. expil. Med.* 47, 141-4(1925).—Rabbits under the influence of insulin were given by mouth, chloral hydrate, amylene hydrate or menthol, a polarimetric study was made of the urine, and the findings were compared with those obtained in the same rabbits without insulin. Insulin caused no change in the amt. of glucuronic acid. The expts. also indicate that glucuronic acid is not a normal intermediate product in the oxidation of glucose. H. F. H.

A clinical and experimental study of the detoxicating function of the liver. II. Alkaloidal detoxication in diseases of the liver. M. HANDEL. *Z. ges. expil. Med.* 47, 145-55(1925).—In order to study the detoxication or the storing up of alkaloids in the liver, the excretion of quinine in the urine was detd. after the administration of 1 g. quinine by mouth. In normal persons the excretion of quinine began in the 3rd hour but in patients showing clinically injury to the liver of various sorts, the excretion of quinine was hastened. HARRIET F. HOLMES

Morphological studies on the importance of the reticulo-endothelial system in intravital hemolysis. C. NATALI. *Z. ges. expil. Med.* 47, 223-43(1925).—Intravital hemolysis was induced in rabbits by the injection of a hemolytic serum. In normal rabbits the cells of the reticulo-endothelial system gave a microchemical reaction showing an Fe-contg. pigment and also a second pigment which gave a negative reaction for Fe but probably was of hematogenous origin with Fe in a stable hemoglobin-like combination. In rabbits previously treated with electrocollargol, a decrease in activity of the reticulo-endothelial system was shown, the cells being able no longer to split up hemoglobin to hemosiderin. HARRIET F. HOLMES

Investigations into benign glucosuria and diabetes mellitus. J. E. HOLST. *Acta med. Scand.* 63, 47-98(1925).—An investigation of 150 persons rejected for life insurance on account of glucosuria; subsequent observation which extended over a period of 5-16 years shows that only 30% have actually had diabetes mellitus while in the remaining the glucosuria must be regarded as non-diabetic. The latter cases fall into 3 groups: glucosuria with cyclic hyperglucemia, renal glucosurias and transitional cases. The value of functional tests depending upon the production of alimentary

glucosuria is disputed. The blood sugar examn. is regarded of greater consequence. Glucosurias with a normal fasting blood sugar are all benign. S. MORGULIS

Experimental studies of anaphylaxis to white wine. V. DE LAVERGNE AND P. FLORENTIN. *Compt. rend. soc. biol.* **93**, 775-6(1925).—Exptl. corroboration of clinical observations that anaphylactic reactions are caused by white wine. S. MORGULIS

The volume of red blood cells in shock. EDGARD ZUNZ. *Compt. rend. soc. biol.* **93**, 863-4(1925); cf. *C. A.* **19**, 3309.—In the dog peptone shock usually causes a diminution of the vol. of the red cells, which is much less in serum anaphylactic shock. On the contrary, in the guinea pig, there is almost always an increase in the cell vol. in anaphylactic shock, or when shock is provoked by intravenous injection of electragol. S. MORGULIS

The precipitation of antitoxic proteins of antidiphtheria serum of the horse by electrodialysis. RAUL WERNICKE. *Compt. rend. soc. biol.* **93**, 879-80(1925); cf. *C. A.* **19**, 3538. S. MORGULIS

Anaphylactic and peptone shock in thyroidectomized dogs. B. A. HOUSSAY AND A. D. CISNEROS. *Compt. rend. soc. biol.* **93**, 886-7(1925).—Thyroidectomized dog sensitized after the operation develop less easily anaphylactic shock than the control dogs. They are likewise less sensitive to peptone shock. S. MORGULIS

Cholesterol in cerebrospinal fluid. GARCIA DEL DIESTRO. *Arch. españoles Pediatría* **9**, 601(1925); *J. Am. Med. Assoc.* **86**, 235.—In 2 cases of attacks of acetoneamia, with symptoms of encephalitis, there was no odor of acetone on the breath, but numerous cholesterol crystals were found in the cerebrospinal fluid. This acetoneamic acidosis encephalitis differed from the epidemic form in the lack of the ocular symptoms. It is suggested that in this recurring hemacidosis, the hypercholesteremia represents a defensive reaction against the acetoneamic intoxication. L. W. RIGGS

Uric acid in the cerebrospinal fluid. P. BAUMRITTER. *Arch. med. enfants* **28**, 681(1925); *J. Am. Med. Assoc.* **86**, 154.—The application of Grigaut's method for the detn. of uric acid in the cerebrospinal fluid in 32 cases showed that the amt. of uric acid was not increased with tuberculous meningitis, but that there is a considerable increase of uric acid in epidemic cerebrospinal meningitis. L. W. RIGGS

Variations in the quantities of nitrogenous substances, particularly urea, in the saliva. A. DESGREZ, R. MOOG AND (MME.) L. GABRIEL. *Compt. rend.* **181**, 755-7(1925)—Urea in the saliva is increased during renal insufficiency. This fact is of diagnostic value. In case the normal flow of saliva is not sufficient to furnish a sample for analysis, the flow may be increased by mech. or chem. excitation. The detn. of urea should be made immediately upon collection, as the saliva loses urea rapidly on standing. Patients with renal insufficiency show an increase of urea N compared with the total N of the saliva. L. W. RIGGS

Protein-fat ratio in diabetic blood. L. O. CHRISTENSEN. *Hospitalstidende* **68**, 969(1925); *J. Am. Med. Assoc.* **86**, 80.—The range in 3 diabetics in coma was, with protein, from 5.77 to 10.47%, while the fat varied only from 0.06 to 0.16%. The fat content was normal in all but 3 of 16 free from coma and of 7 in 11 with impending coma. No subnormal fat percentage was recorded in any instance, and an exceptionally high content only once. In cases of nephrosis the hydremia is more pronounced than in diabetes; possibly this may have something to do with the lipemia common with nephrosis. In one case of the latter the serum protein was 5.09 and the blood fat 0.4%. L. W. RIGGS

Characteristic changes in blood chemistry in whooping cough. J. C. REGAN AND A. V. TOLSTOOUHOV. *J. Am. Med. Assoc.* **86**, 191-2(1926).—A total of 200 analyses of the blood was made in whooping cough. The most characteristic changes were the lowering of the H-ion concn. and a diminution of the inorg. P content of the blood. L. W. RIGGS

Changes in the blood resulting from duodenal fistula. WALTMAN WALTERS, A. M. KILGORE AND J. L. BOLLMAN. *J. Am. Med. Assoc.* **86**, 186-91(1926).—This study of chem. changes in the blood accompanying clinical and exptl. duodenal fistula has shown that in all instances there are increasing alkalosis, decreasing concn. of chlorides in the blood serum, and progressive rise in blood urea. The intravenous injection of NaCl in concd. soln., even if sufficient in amt. to raise the blood chlorides to normal, has practically no effect in lengthening the life of an animal with duodenal fistula. However, if a sufficient vol. of water is added to the NaCl soln. and given twice daily, life may be maintained 3 weeks or longer, during which time the blood chlorides are raised to their normal level, and the accumulation of non-protein N in the blood is prevented. Intravenous injection of glucose solns. and of Na₂SO₄ solns., although they assist in the elimination of the retained non-protein N in the blood, have no effect on

the blood chlorides. These findings suggest that the fluid balance plays some part in the toxemia accompanying duodenal fistula. Parallel studies of changes in the blood coincident to exptl. gastric fistula show that, with an increase in the amt. of acid discharged through the fistulous tract, the increase in the blood alkali reserve is still greater. The total amt. of HCl and the amt. of chlorides discharged from the gastric fistula were sufficient to explain the increase in the alky. of the blood and the decrease in its chloride content. To det. how much of the effect could be attributed to loss of bile and pancreatic secretion, the common bile duct and both pancreatic ducts were transplanted into the jejunum in 2 dogs, the loss of bile and pancreatic secretions being thus prevented. These dogs showed the same chem. changes in the blood as the dogs with duodenal fistula whose ducts had not been transplanted, and pursued the same clinical course.

L. W. RIGGS

Trypsin studies with normal and diseased infants. J. LUKÁCS. *Magyar Orvosi Archivum* 26, 473-83(1925).—The feces of new-born infants contain 60-80 units of enzyme during the first few days, compared with 10-30 units for older children. After the meconium period the amt. of enzyme drops to 20 or lower, to rise again during the 2nd to 4th weeks to 20-40 and after 3 months to 40-60. In all cases of infections the enzymes decrease and remain on a much lower level than during health. Children with rickets have 160-600 units of trypsin. If such children develop an intercurrent infection, their trypsin units decrease to a less extent than is the case with children without rickets.

L. W. RIGGS

Histologic study of the sympathetic ganglia of rabbits fed cholesterol. Etiology of arteriosclerosis. P. ORMOS. *Magyar Orvosi Archivum* 26, 505-12(1925).—Rabbits with arteriosclerosis and fed with cholesterol develop lipoidal accumulations, swelling of the cell, and a destruction of nucleus and cytoplasm. Cholesterol produces arteriosclerosis and also an affection of the vegetative nervous system. The simultaneous presence of cholesterol and of oscillations of the blood pressure result in arteriosclerosis.

L. W. RIGGS

Investigations on the passage into the cerebrospinal liquid of the dye uranin. OTTO JERVELL. *Norsk Magazin Laegevidenskaben* 86, 757-811(1925).—To 43 patients, most of them suffering from various diseases of meningitic nature, were given about 2 g. of uranin (the Na salt of fluorescein) in the form of tablets or intramuscular injections and after 3 hrs. the spinal liquid was examd. There was a certain correspondence between the color of the liquid and the pathologic condition of the patient.

ALFRED N. RICHARDS

Calcium and potassium chlorides in the treatment of arterial hypertension. W. L. T. ADDISON AND H. G. CLARK. *Can. Med. Assoc. J.* 15, 913-5(1925).—Three or 4 weeks' administration of CaCl_2 will produce a definite fall in blood pressure, with coincident improvement of symptoms, and disappearance of edema. If CaCl_2 is ineffective, subsequent administration of KCl is often successful.

A. T. CAMERON

The occurrence and activity of the rarer elements. K. SPIRO. *Ergebnisse Physiol.* 24, 474-516(1925).—The occurrence, the physiological properties, and the therapeutic value of Cu, Au, Ag, Hg, Mg, Mn, Fe, Pb, Sn, Zn, Si, As, Sb, Bi, V, S, Se, Cl, Br, I, F and NH_4 are discussed.

H. J. DEUEL, JR.

Influence of electrolytes on the action of insulin. J. ABELIN AND E. GOLDNER. *Klin. Wochschr.* 4, 2446-7(1925).—The effectiveness of insulin is reduced if Na_2HPO_4 is fed before the insulin is administered. NaH_2PO_4 , on the contrary, increases the effectiveness of insulin. From this it might be concluded that the H and OH ions are the detg. factors rather than the PO_4 ion. The matter does not, however, seem to be that simple because a mixt. of NaCl, Na_2SO_4 and NaHCO_3 increases the effectiveness of insulin.

MILTON HANKE

Action of chlorophyll on nerve-muscle preparations. T. GORDONOFF AND T. HOSOKAWA. *Z. ges. exptl. Med.* 46, 454-8(1925); cf. *C. A.* 19, 2241.—Addition of chlorophyll increases the activity of a nerve-muscle prepn. The result is the same whether the chlorophyll is applied to the muscle or to the nerve. An exhausted nerve-muscle prepn. commences to contract again when chlorophyll is added. Colloidal chlorophyll, Na chlorophyll and Na chlorophyll Siegfried were used.

HARRIET F. HOLMES

Further studies on the insulin problem. G. HETÉNYI. *Z. ges. exptl. Med.* 46, 600-6(1925); cf. *C. A.* 19, 2706.—The primary action of insulin is omniscellular. The hypoglycemic complex resulting from an overdose of insulin is dependent on the liver.

The overdose of insulin may produce a paralysis of the secretory cells of the liver or may produce changes on the surface of the cells interfering with the excretion of sugar.

HARRIET F. HOLMES

Factors influencing the excretion of urea. II. Diuresis and caffeine. HELEN BOURQUIN AND N. B. LAUGHTON. *Am. J. Physiol.* **74**, 436-50(1925); cf. *C. A.* **18**, 2758.—The ratio: urine urea N/ blood urea N is exceedingly high at the onset of diuresis, drops on continuation of diuresis to a level above that established at lower vols. and is depressed for a long period after diuresis has subsided. In dogs which have been without food and water for 12 hrs. the ratio varies with the vol. output within certain limits. Caffeine (0.5-1 mg./kg.) slightly increases the urea output. The changes in NH_3 and f. p. depression are similar, suggesting a lag in the readjustment of the concn. of excreted solids behind the change in vol. output. M. J.

Secretin. IX. Its relation to the activity of skeletal muscle. N. B. EDDY AND ARDREY W. DOWNS. *Am. J. Physiol.* **74**, 489-96(1925).—Secretin preps. increase the working power of the muscle and delay the development of fatigue. The effect may be influenced by, but does not depend on, the reaction of the soln. It is due neither to histamine nor to the vasodilator substance but to a substance which disappears during perfusion. The vasodilator agent also disappears during perfusion but at a different rate. The effect is considerably diminished in curarized dogs, which indicates action on the motor nerve endings. Glucose also diminishes the effect although secretin preps. cause an increased sugar output. MARY JACOBSEN

The heart poisons of the digitalis plant and related compounds. A. WINDAUS. *Nachrichten Ges. Wiss. Göttingen* **1924**, 237-45.—A review. MARY JACOBSEN

Effect of bismuth upon red blood corpuscles. A. SIMON. *Biochem. Z.* **159**, 424-31(1925).—On injection of K Bi tartrate into dogs, a decrease in red blood cells is noted. *In vitro* expts. upon the blood of humans show that the Bi soln. (except in very small concns.), causes hemolysis of the cells, or decreases their resistance to hemolysis. W. D. L.

Cholesterol studies in lead poisoning. KRETSCHNER AND FRIEDER. *Biochem. Z.* **164**, 44-6(1925).—The cholesterol content of the serum is diminished, while in whole blood it is increased, during Pb poisoning. Ordinarily the cholesterol content is greater in serum than in whole blood, but in the case of workmen suffering from plumbism the condition is reversed. S MORGULIS

Electrolytic study of the circulation of gold in the organism. SVEND LOMHOLT. *Compt. rend* **181**, 821-3(1925).—The electrolytic feature applies only to the detn. of Au in the tissues. The latter is treated with fuming HNO_3 and the ash from this treatment is dissolved in boiling aqua regia, the soln. is made slightly alk. with NH_3 and after the addn. of 0.75 g. KCN and diln. to 75 cc., the Au is deposited under an e. m. f. of 4 v. on a Pt cathode and is weighed. The production of Pt black must be avoided. After an intravenous injection of 26.25, 37.5 and 37.5 mg. of Au in 3 rabbits, resp., Au was found principally in the kidneys, large intestine and liver, with smaller amts. in other organs. Both the distribution and the elimination of Au by urine and feces resemble those of other heavy metals such as Hg, Bi and Pb. In 2 human subjects the injection of 187.5 and 150 mg. was followed in 9 and 14 days by the recovery of 30.9 and 42.46 mg., resp. One-third was eliminated in the feces, the remainder in the urine. L. W. RIGGS

I—ZOOLOGY

R. A. GORTNER

Conditions for calcareous metabolism in oysters and other marine animals. J. H. ORTON. *Nature* **116**, 13(1925).—A summary. There appears to be a min. temp. below which shell is not laid down, and above which shell-material may be produced automatically. In the good shell-growth of warm and relatively cold, wet seasons in Great Britain the corresponding hydrographical conditions are, resp., high estuarine salinities, alkalinities, and temps., and low fluctuating salinities with medium temps. and (probably) alkalinities, together with a smaller quantity of available food material in the latter case. B. C. A.

Changes in the protoplasm of Nereis eggs induced by β -radiation. ALEXANDER FORBES AND CATHARINE THATCHER. *Am. J. Physiol.* **74**, 567-78(1925).—A sediment zone or increased opacity and finer granulation was observed in *Nereis* eggs fertilized after β -irradiation. Decreased viscosity alone or chem. changes are responsible for the phenomenon. MARY JACOBSEN

Oxygen metabolism in Drosophila melanogaster. M. R. CLARE. *Biol. Bull.*

Marine Biol. Lab. **49**, 440–60(1925).—A knowledge of metabolism in *Drosophila* pupae cannot be attained if sole dependence is placed on the wt. of respiring tissues as a guide. Only in a rough way do pupal wts. show a correspondence with the trends of metabolic rates. Rates of O consumption are very irregular. No metabolic difference was found between the sexes or between inbred and non-inbred stocks. L. W. RIGGS

The influence of saline solutions on the resistance of young eels to fasting. UMBERTO D'ANCONA. *Atti accad. Lincei* [6] **2**, 443–9(1925).—Under the conditions of concn. and temp. used young eels resist fasting better in saline solns. (alkali and alkali earth metals) than in soft water and undergo less loss in total wt., in dry wt. and in inorg. substances (ash content). E. J. WITZEMANN

12—FOODS

W. D. BIGELOW

Display of the composition of foods for demonstration purposes. F. H. LORENTZ. *Z. Nahr. Genusssm.* **50**, 257–64(1925).—A description, with illustrations, of a method of demonstrating food values at an agricultural fair. WILLIAM J. HUSA

Iron in food products. C. MASSATSCH. *Pharm. Ztg.* **70**, 1790–1(1925).—The article deals mainly with the invalid food preps. Tropon and Iron Tropon relative to the amt. and nature of their Fe content. It is shown, contrary to the claims of the manufacturer, that the Fe of Iron Tropon is present essentially as inorg. hydroxide adsorbed by, or pptd. on, the protein base, being partially dissolved in the stomach by the HCl, but mainly expelled by the intestine, since the contents of this organ cannot on account of their alkalinity effect further soln. W. O. E.

Iron in food products. TROPONWERKE DINKLAGE & Co. *Pharm. Ztg.* **71**, 39–40(1926).—A refutation of the criticisms of Massatsch in preceding abstract. W. O. E.

Transformation of nitrogen compounds (proteins) in preserved food products. L. SETTIMI. *Atti accad. Lincei* [6] **1**, 396–400(1925).—Analyses at different times of fish sauce in a glass container, wheat flour, tinned meat and cheese, show, in all cases, progressive transformation of insol. N compds. into equiv. quantities of sol. N compds. B. C. A.

The use of the fermentation-reductase test for the grading of milk. E. R. HISCOX AND URSULA STARLING. *J. Hyg.* **24**, 164–75(1925).—This test is not reliable in distinguishing between grade A certified milk and commercial milk, or for detecting the presence of coliform organisms. JOHN T. MYERS

Chemical bacteriological factors in the ripening of cheese. I. J. ZAYKOWSKY AND N. SLOBODSKA-ZAYKOWSKY. *Biochem. Z.* **159**, 199–215(1925).—The effect of NaCl and lactic acid upon the action of rennet upon milk is observed. The changes of acidity of the milk and whey, and the total N in the whey obtained when various amts. of NaCl and lactic acid are used with the rennet are tabulated. W. D. L.

Determination of the hydrogen-ion concentration of cheese by the quinhydrone electrode. SÖNCKE KNUDSEN. *Z. Nahr. Genusssm.* **50**, 300–6(1925).—Cheese was carefully rubbed in a mortar with twice its wt. of H₂O and any undissolved material removed by centrifuging. The p_H of this liquid is not exactly the same as that of the cheese. A better method was to rub 5 g. of cheese with 0.1 g. of quinhydrone, pack this mixt. into a glass tube 30 mm. long and of 3–5 mm. inside diam., and place in it to a depth of 15–20 mm., a Pt wire or foil. 3.5 N KCl was used as intermediate liquid and the reference quinhydrone electrode was 0.01 N in HCl and 0.09 N in KCl. The accuracy is indicated by the results of 20 measurements on the same cheese with 5 different electrodes; the readings varied from 5.81 to 5.90 p_H . The p_H is markedly influenced by the salt content of the cheese. WILLIAM J. HUSA

Investigations of natural and synthetic sweet substances. I. Studies on the degree of sweetness of saccharin and dulcin. KURT TAUFEL AND BERNHARD KLEMM. *Z. Nahr. Genusssm.* **50**, 264–73(1925).—T. and K. confirm and extend the work of Paul (C. A. **15**, 1361, 3881; **16**, 973, 2558) and Pauli (C. A. **16**, 974). The degree of sweetness (compared with sucrose) of saccharin and dulcin (*p*-phenetyl carbamide) increases with increasing concn. of alc. in aq.-alc. solns. Interpolation formulas, and also a graphical method, are given for calcg. the compn. of all mixts. of saccharin and dulcin which would equal in sweetness a sucrose soln. of any given concn. WILLIAM J. HUSA

Treatment of flour with chlorine and the so-called Golo method of improving flour. M. P. NEUMANN AND H. KALNING. *Landw. Jahrb.* **61**, 305–19(1925).—Flour rapidly absorbs Cl or Cl with 0.5–1.5% of nitrosyl chloride, as in the Golo treatment, and for

normal concns. of Cl (0.015–0.02%) there is no odor and no HCl or HNO₃ can be detected. The treatment increases the swelling power of the colloidal substances and the strength of the flour, and also its acidity and the soly. of the N compds. The activity of the enzymes and the keeping qualities are not affected. Excessive Cl treatment of soft wheats has no beneficial effect. With the correct amt. of Cl the yellowish color of the flour becomes considerably paler, and an excessive treatment gives a grey chalky white color. B. C. A.

The organic acids of tomatoes, besides citric acid, and their state of combination. ARTHUR BORNTRÄGER. *Z. Nahr. Genussm.* 50, 273–300(1925).—B. concludes that the only org. acids present in sound green, half-ripe and ripe tomatoes are citric and malic acids. In softened but not entirely spoiled tomatoes succinic acid was found. In ripe tomatoes citric acid occurs chiefly in the form of primary citrates, with less secondary citrates; malic acid is present mainly as an acid salt. The content of free acid, calcd. as malic, was never over 0.05%. The % of phosphates in tomato juice increased with increasing ripeness. WILLIAM J. HUSA

Heat penetration in canned crabs. C. R. FELLERS. *Canning Age* November, 1925, 900.—Investigations indicate that the slow heat penetration of dry pack crab meat renders the ordinary com. exhausting and cooking processes inadequate to protect against spoilage. A high initial temp. and either the addn. of org. acids or an increased process are necessary for complete safety. THEO. MARKOVITS

Water-soluble solid content of fruit preserves and jams. C. P. LATHROP AND W. LOWE WALDE. *The Canner* September, 1925, 23.—The preserves are classified into 2 groups, based on their water-sol. solid content, in order to arrive at the best water-sol. solid figure for jams and preserves. The max. and min. water-sol. content of the more important fruit preserves are tabulated. THEO. MARKOVITS

Early autolytic and bacterial transformation of fish muscle proteins. G. B. REED. *Pub. Health J. (Can.)* 16, 568–77(1925).—There was a slight increase in non-coagulable N and N as NH₃ in macerated haddock muscle kept under C₇H₈ at 25° for 24 hrs. and a conspicuous increase in 48 hrs. Haddock fillets were heavily infected with bacteria similar to those of the gut and the slime of the fish. When these bacteria were permitted to develop in fish muscle at 25° there was only slightly greater increases in non-coagulable N and N as NH₃ during the first 24 hrs. than was produced by autolysis alone; but in 24–48 hrs. of incubation the bacteria produced very much greater protein transformation than was produced by autolysis during the same period. R. E. THOMPSON

Researches on cacao. I. Detection of shells. W. PLÜCKER, AD. STEINRUCK AND FR. STARCK. *Z. Nahr. Genussm.* 50, 307–15(1925).—During the process of manuf. in iron app., cacao may show an increase in Fe and in residual phosphates. Detns. of crude fiber and of residual phosphates give no accurate criterion of adulteration of cacao or chocolate with shells, but an accurate insight may be obtained by the microscopic detn. of stone cells, for which a procedure was devised. A bibliography is given of (1) chem., (2) microscopic, (3) phys. methods for detection of shells in cacao. WILLIAM J. HUSA

Whey research factory at Haslington: pig feeding experiments with lactose residues. J. GOLDING AND W. B. MORRIS. *J. Ministry Agr.* 32, 911–8(1926).—After the removal of the easily crystd. lactose from concd. whey, the residue, a paste of the consistency of butter (lactose paste), was fed to pigs directly or after mixt. with brewer's grain (lactose feed). Meat production was slightly more economical in pigs fed lactose feed than in controls in which equal amts. of bean meal were substituted for the lactose feed. Inclusion of 10% lactose paste also gave satisfactory results. Superior quality of flesh was obtained with lactose products in the diet. H. B. LEWIS

Lactose feed as a food for dairy cows; a preliminary experiment. K. W. D. CAMPBELL. *J. Ministry Agr.* 32, 918–9(1926).—Lactose feed (cf. preceding abstr.) has a value similar to that of bean meal in the diet of milch cows. H. B. LEWIS

The present status of forage preservation. K. SCHARRER AND A. STROBEL. *Z. angew. Chem.* 38, 1034–40(1925).—A review, with numerous references, of the action of microorganisms in the preservation of green fodder. Feeding expts. with silage by H. Niklas, S. and S. are summarized. Cf. *Landw. Jahrb.* 61, 321(1925); cf. C. A. 19, 1925. MARGARET W. MCPHERSON

Composition and food value of cane sirup (PAINE) 28. The electric current in the sterilization of milk and other liquids (BEATTIE, LEWIS) 11C. Purification of dairy wastes (DIENERT) 14. Apparatus for leaching and filtration [for coffee, etc.] (U. S. pat. 1,570,807) 1. Float and lever device for indicating the density of acids [for milk or cream] (U. S. pat. 1,570,717) 1.

PLIMMER, R. H. A. AND PLIMMER, VIOLET G.: **Food and Health**. London: Longmans, Green and Co. 64 pp. Paper 2s. net, cloth 3s. net, Food chart 3d. Reviewed in *Nature* 117, 44(1926).

Milk sugar. H. V. DUNHAM. U. S. 1,571,626, Feb. 2. Whey is boiled at atm. pressure, by direct fire heat, while air is blown on its surface to prevent excessive foaming, until a concn. of at least 20° Bé. at a temp. of 88° is attained. Pptd. albuminous substances are filtered out and the whey is then further concd. by boiling at atm. pressure.

Preserving milk, fruit juices, etc. P. M. HEYERDAHL. Brit. 236,247, Feb. 1, 1924. Milk, fruit juices and other non-oily liquid food substances are subjected to pressure reduction to remove air and then are sprayed into an inert gas such as CO₂ alone or mixed with N, preferably under 2 atm. pressure, heated to a pasteurizing temp. and packaged.

Carbonating milk and cream. D. SWEENEY. U. S. 1,570,975, Jan. 26. Mech. features.

Pasteurizing and deodorizing cream. C. F. ROGERS. U. S. 1,570,646, Jan. 26. Cream or milk is heated to a temp. (usually about 60°) below that productive of detrimental change in the butter-fat and at which the casein and curd content becomes hardened, passed while heated into an unheated vacuum chamber which causes an immediate drop of temp. and liberation of volatile substances and gases and withdrawn through the condenser.

Antirachitic vitamin development. H. STERNBOCK. Brit. 236,197, June 30, 1924. Actinic rays such as the ultra-violet rays from a Hg vapor lamp are used for increasing the antirachitic properties of foods and medicines such as yeast, cereals, grain, oils and fats, butter or milk.

Bread. T. B. WAGNER and C. A. GLABAU. Brit. 235,874, June 21, 1924. In order to eliminate the usual fermentation period in making leavened bread and the like, substances are added to the dough which serve as yeast activators, foods, or stimulants and gluten-maturing agents. Among the substances employed are NH₄ phosphate or sulfate, K persulfate, KClO₄ or a compn. obtained from acid steep water from maize which is neutralized with Ca(OH)₂, heated and the resulting ppt. washed and dried. Malt exts., buttermilk, acid salts or lactic, malic, mucic acids or HCl or H₃PO₄ also may be used.

Treating flour and other food materials with sterilizing gases. F. H. LORING. Brit. 235,930, March 15, 1924. N oxides, Cl or other halogen, SO₂Cl₂, phosphoryl chloride or mixts. of these gases with N oxides and air passed through an elec. arc are used to avoid rancidity and development of injurious organisms. An app. is described.

Baking powder containing yeast. A. POLLAK. Brit. 236,210, June 24, 1924. The usual constituents of baking powder are mixed with yeast which has been liquefied and dried at low temp. either before or after association with the other ingredients. The liquefaction of the yeast may be effected by use of dry sugar, concd. malt ext. or use of lactic or other org. acids, preferably with sugar or a similar substance. Other substances may be added, *e. g.*, albumin, fat, starch, flour, casein, dried milk, malt ext. or powder, phosphate or other salts, diastase from fungi, which are preferably added to the liquefied material before drying.

Food preparations from autolyzed fish, autolyzed yeast, etc. M. KAHN, E. LEBRETON and G. SCHAEFFER. Brit. 235,834, June 17, 1924. Yeast is autolyzed for 3–5 days at 40° and added to an equal or greater quantity of crushed fish contg. viscera. The autolyzed mass is sieved, filtered and dried. A residue is obtained adapted for use as a fertilizer or for the manuf. of phosphates, glues or gelatins. Greases, substances useful in tanning and a nitrogenous liquid from which food ingredients may be obtained are also produced.

Foods produced by autolysis of fish, etc. M. KAHN. Brit. 236,158, June 25, 1924. In processes such as described in Brit. 218,679 and 218,680 (*C. A.* 19, 548) non-miscible antiseptics are added which are of different sp. gr. to insure distribution through the material of the antiseptic, *e. g.*, CHCl₃ and toluene.

Foodstuff from corncobs. H. HEUSER. U. S. 1,570,891, Jan. 26. A food for animals is prepd. by mixing corncobs with germinated cereal material such as malt so that proteolytic and amylolytic conversion products are formed from the corncobs. The material may also be subjected to a lactic fermentation.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Chemical industry in 1925. MAX MUSPRATT. *Ind. Chemist* 2, 3(1926). E. H.
Progress in the fine chemical industry, 1925. F. H. CARR. *Ind. Chemist* 2, 9-10 (1926). E. H.

The application of research to industry. A. D. LITTLE. *J. Chem. Education* 2, 959-70(1925). E. H.

Chemical engineering progress during 1925. J. W. HINCHLEY. *Ind. Chemist* 2, 4-6(1926). E. H.

Economic and technical characteristics of chemical manufacturing. CHAPLIN TYLER. *Chem. Met. Eng.* 32, 938-41(1925).—A general discussion giving statistics, ratio of capital investment to value of products, etc., and showing the continuity of the major unit operations in the principal chem. engineering industries. W. B. PLUMMER

The problems of Muscle Shoals. C. H. MACDOWELL. *Separate*, 36 pp (1925).—A report accepted by the Executive Committee of the National Fertilizer Association for submission to the Muscle Shoals Inquiry. E. H.

Muscle Shoals report. ANON. *Ind. Eng. Chem.* 18, 196-7(1926).—A discussion of the 2 reports (majority and minority) made by the Muscle Shoals Commission on the utilization of the war-time N-fixation plants Nos. 1 and 2. W. B. PLUMMER

American Society for Testing Materials, Tentative Standards 1925. *Separate*, 876 pp.(1925); cf. *C. A.* 19, 3331.—Tentative specifications are given for: steel tie plates; C-tool steel; high-speed tool steel; low-C-steel track bolts; elec. cast-steel anchor chain; steel plates for forge welding; wire for concrete reinforcement; C-steel castings for railroads; structural Si steel; C-steel castings and alloy steel bolting material for high-temp. service; W powder; spiegeleisen; Fe-Mn; Fe-Si; Fe-Cr; Fe-V; hollow stay-bolt iron; hot-dipped galvanized sheets; P-Sn; P-Cu; Si-Cu; Al-base alloy sand castings; bronze trolley wire, soft rectangular Cu wire; hot-rolled Cu rods for wire drawing; Mn-bronze ingots and castings; Muntz-metal condenser tube plates; non-ferrous alloys for railway equipment; white-metal bearing alloys; Al ingots and sheets; Al for use in manuf. of iron and steel; non-ferrous insect screen cloth; compressive strength of cement mortars; crushing strengths of sewer pipes; CaO and hydrated lime for various uses; concrete aggregates; concrete building brick; hollow burned-clay tile for walls and floor; tung oil; soy-bean oil; foots permissible in linseed oil; purity of raw and boiled linseed oil; dry bleached shellac; Fe oxide and hydroxide; lithopone; lampblack; boneblack; chrome yellow; chrome green; stone and slag for highway construction; sand for asphalt and bituminous concrete pavements; CaCl₂ for dust prevention; asphalt cement; tar for road surface treatment, tar cement; pitch for stone block filler; structural Douglas fir; acid-resisting asphalt mastic; asphalt roofing materials; tar-satd. roofing felt; wooden shipping containers; rubber-insulated wire and cable; steam hose; rubber insulating tape; textile-testing machines; sieves for testing. Tentative methods are given for sampling and analysis of ferro-alloys; analysis of Al and its light alloys; analysis of limestone, quicklime and hydrated lime; sampling, inspecting, packing and marking quicklime products; testing resistance of fireclay brick to spalling action; sampling hardened concrete; testing shellac varnish; testing for coarse particles in paint pigments; analysis of white linseed-oil paints; distn. test of petroleum products and natural-gas gasoline; testing m. p. of petrolatum; analysis of grease; penetration test for grease; detn. of viscosity of petroleum products and lubricants; test for color of lubricating oils, of petrolatum and of refined petroleum oil; test for burning quality of kerosene and long-time burning oils; test for S in petroleum products; test for steam emulsion of lubricating oils; test for sapon. no.; test for neutralization no. of petroleum products and lubricants; test for C residue of lubricants; test for cloud and pour points of petroleum products; detn. of d., distn., S, C residue, pour point, viscosity and H₂O in gas oils; detn. of d. of road oils, tars, asphalt, asphalt cement and tar pitches; detn. of clay in highway construction materials; decantation test for fine aggregates; mech. analysis of subgrade soils; detn. of moisture equiv. of subgrade soils; detn. of consistency of cement concrete; detn. of bitumen; detn. of bitumen sol. in CCl₄; ductility of bituminous materials;

fibers; detn. of scoured content in grease wool, etc.; tension impression testing of metallic materials; Brinell hardness testing; verification of testing machines. Tentative recommended practice is given for carburizing and heat treatment of carburized objects; for thermal analysis of steel. Tentative definitions are given for terms relating to lime and to the gypsum industry; for sand; for terms relating to coal, to coke, to textile materials, to methods of testing, to sp. gr.; for screen (sieve). Tentative rules are given for inspection of concrete and reinforced concrete work. Tentative revisions are given for A. S. T. M. standard specifications for C-steel and alloy-steel forgings for various purposes; welded and seamless steel pipe and steel and iron boiler tubes; welded wrought-iron pipe; staybolt, engine-bolt and extra-refined wrought-iron bars; malleable castings; copper in various shapes; light Al casting alloys; bronze trolley wire; seamless admiralty condenser tubes and ferrule stock; high sheet brass; naval brass rods; cement; cement-concrete sewer pipe; fire tests of materials and construction; paving brick; hydrated lime; turpentine; broken slag. Tentative revisions are given for recommended practice in heat treatment of case-hardened steel objects; for standard methods of testing gypsum and gypsum products, of distn. test of bituminous material suitable for road treatment, of sampling and analysis of coke and coal, of sampling creosote oil and of testing molded insulating materials; for standard definitions of terms relating to paint specifications. E. H.

Third annual review number. *Chem. Met. Eng.* 33, No. 1 (1926).—Trade conditions are given for the following industries for 1925: fertilizer materials, S, wood-distn. products, by-product coke, pitch and road materials, insecticides, alcohols and volatile solvents, lithopone, ammonia, vegetable oils, dyes, lead compounds and H_2SO_4 . Distribution statistics for the important chemicals are given. E. H.

Plowshares from chemistry's swords. D. H. KILLEFFER. *Ind. Eng. Chem.* 18, 253-8 (1926).—The reconstruction of the smokeless-powder plants at Hopewell, Old Hickory and Nitro is discussed. E. H.

The utilization of volcanic steam in Larderello. OKRASSA. *Chem. App.* 13, 2-3 (1926); 4 cuts.—Description of the Bringham evaporator. Cf. *C. A.* 18, 300. J. H. MOORE

Recovery and use of waste products. III. In the paper and sugar industries. J. B. C. KERSHAW. *Ind. Chemist* 1, 513-7 (1925); cf. *C. A.* 20, 634.—This article is a digest of comparatively recent literature dealing with savings in the paper and sugar industries under the following heads: (1) fuel and heat losses, (2) waste lyes from the soda process, (3) waste sulfite liquors, (4) sugar from molasses, (5) potash from molasses, (6) reduction in amt. of molasses, (7) Steffens waste-water treatment, (8) scum and vegetable wastes, (9) recovery of diatomaceous earth and NH_3 from sugar waste. E. G. R. A.

The utilization of (legally) unprotected things. JULIUS EPHRAIM. *Z. angew. Chem.* 39, 20-3 (1926).—A lecture discussing the limits, under German law, to which one may go in imitating a competitor's product, or in marketing goods upon which patents have expired or other legal protection has been allowed to lapse. It is contended that to make a downright copy of a given thing is unfair competition, but if a new arrangement of the old ideas be utilized it is legal. W. C. EBAUGH

Losses in factories for inorganic chemicals. RUDOLF PÜRINGER. *Oesterr. Chem.-Ztg.* 28, 160-2 (1925).—A general discussion of losses in processes of extn., pptn. and crystn., with suggestions for improving operating conditions. W. C. EBAUGH

Progress in adsorption technic. R. KOETSCHAU. *Chem. Umschau Fette Oele Wachse u. Harze* 32, 280-1 (1925).—A general review of bleaching by means of such adsorbing agents as activated C and silica gel. P. ESCHER

The importance of chlorine in chemical warfare. A. A. FRIES. *Trans. Am. Electrochem. Soc.* 49 (preprint) (1926).—After a brief description of the first Cl gas attack in 1915, the disadvantages of Cl in chemical warfare are pointed out. Among these disadvantages is the high vapor pressure, necessitating containers of very rugged construction. Furthermore, about 10 times as much Cl is required to produce the same toxic effect as some of the other war gases. It is probable that Cl as such will not be used in the future as a standard chem. warfare agent. Cl is still used in conjunction with phosgene to increase the rate of vaporization. Cl forms the one essential raw material for a no. of war gases. The manuf. and properties of phosgene, mustard gas, lewisite, tear gases and toxic smokes are briefly touched upon. C. G. F.

Unit Processes in Chemical Engineering. Edited by Chemical and Metallurgical Engineering. New York: McGraw-Hill Co., Inc. 91 pp.

Resolving emulsions. E. E. AYRES, JR. U. S. 1,570,987, Jan. 26. Emulsions such as those of cottonseed oil soap stock are treated with a reagent, *e. g.*, Ca oleate in alc. and glycerol, or CaCl_2 , which forms, by reaction in the continuous phase, a substance in a state of colloidal dispersion therein and which will act as an emulsifying colloid to reverse the form of the emulsion.

Purifying solutions containing titanium, thorium and other metals. SPENCER, CHAPMAN & MESSEL, LTD. and J. B. LIEBERT. Brit. 236,087, Oct. 20, 1924. Solns. obtained in the treatment of ilmenite or monazite with H_2SO_4 or other similar solns. are clarified by adding a small quantity of glue, gelatin, albumin or casein.

Separating liquids by gravity. C. F. HIGGINS. Brit. 234,875, Nov. 24, 1924. Liquids such as oil and H_2O are passed through a tank divided into compartments so that liquid flowing upward in one compartment passes over a weir into the next, in which the flow is downward and the lighter liquid seps. on the surface.

Dehydrating liquids. A. S. EISENBAST. U. S. 1,570,626, Jan. 26. In sepg. H_2O from oils, varnishes or from other non-aqueous liquids, substantially dehydrated diatomaceous earth is mixed with the material and the mixt. is subjected to filtration.

Liquefaction and rectification system for separating constituents of air or other gaseous mixtures. C. C. VANNUYS and W. WILKINSON. U. S. 1,571,461, Feb. 2.

Rubber electrical insulation. WESTERN ELECTRIC CO., LTD. Brit. 236,026, June 11, 1924. Rubber insulation after being applied to submarine cables or the like is heated at about 95° for several hrs. to drive out moisture and then treated with melted paraffin for 15 min. to fill the pores in the outer portion of the rubber.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

The science of ground water supplies. G. THIEM. *Z. Ver. Gas u. Wasserfach* **65**, 166-9 (1925).—Most German cities use ground water as civic supplies. B. H. P.

Kentucky health board rates water supplies. F. C. DUGAN. *Eng. News-Record* **95**, 957 (1925).—Based on the character of the raw water, methods of treatment, operation of the plant and analyses of the water supplied 30 of the 91 water systems inspected by the State Board of Health in Kentucky are rated as good, 28 doubtful, 29 bad and 4 no rating but probably good. A list of the cities inspected, with their classification, is given.

California railroad commission and the water works man. M. R. MACKALL. *J. Am. Water Works Assoc.* **15**, 64-79 (1926). R. E. THOMPSON

Effect of impounding reservoir on water at Greensboro, N. C. C. W. SMEDBERG. *J. Am. Water Works Assoc.* **15**, 62-3 (1926). D. K. FRENCH

How laboratory supervision saved Omaha (Neb.) \$9000 per year. K. C. ARMSTRONG. *Eng. News-Record* **96**, 119 (1926).—The quantities of chemicals required to effect coagulation of the water at Omaha are detd. by lab. trials in a series of jars. It is estd. that the employment of this method will effect a saving of \$9000 during 1925 as compared with previous 6 years, notwithstanding the fact that the raw water was more turbid than in 1924. Addn. of a small dose of FeSO_4 ($\frac{1}{4}$ grain per gal.) enables the alum dosage to be reduced from $2\frac{1}{4}$ to 1 grain per gal. If larger amts. of FeSO_4 are employed, more lime is required, and it is, therefore, more economical to increase the alum when higher dosage of coagulant is needed. Lab. expts. indicated that the FeSO_4 should be added first, but in practice it has been found satisfactory to mix the alum and FeSO_4 in soln. tanks and add the soln. contg. both chemicals to the water to which lime has been previously added.

Well flow measured by pitometer checked by orifice. JOHN N. BROOKS. *Eng. News Record* **95**, 683-4 (1925).—Brief details are given of measurements of yield of a well by the pitometer and orifice methods, which agreed to within 1.2%. The yield of the well was approx. 1000 gals. per min.

Foaming in coagulating basins and air-bound filters. G. D. NORCOM, *et al.* *J. Am. Water Works Assoc.* **15**, 42-51 (1926).—Foaming is considered to be due to suspended matter, air and CO_2 gas generated as part of the alum reaction, coupled with

temp., surface tension and other phys. phenomena. Aside from its appearance it is considered harmless. It is suggested that there is some connection between foaming, and air-bound filters.

D. K. FRENCH

Sterilization with freshly prepared hypochlorite. H. A. LILLY. *J. Am. Water Works Assoc.* 15, 60-1(1926).—L. describes an inexpensive device for prepg. hypochlorite, using Cl and an alkali and feeding it into water.

D. K. FRENCH

Progress in the purification of water supplies. N. J. HOWARD. *Contr. Rec.* 39, No. 52, 133-8(1925).—Extensive review of progress in water purification during 1925. The employment of double filtration in dealing with heavily polluted and turbid waters is extending. A soln. composed of alum, Na_2CO_3 and NaOCl , the concn. of the latter being varied in proportion to the Cl-consuming power of the water, is being employed in Ontario in the prepn. of certain acid waters for filtration. Prechlorination and CuSO_4 treatment of a slow sand filter at Toronto, Ont., recently, in an effort to increase the length of run between scrapings in the early spring when the microscopic content of the raw water was high, proved unsuccessful. Superchlorination and dechlorination has recently been experimented with at Toronto, Ont., as a means of eliminating the medicinal taste which occasionally occurs following chlorination, and this process will be tried on a large scale in the near future. Also in *Surveyor* 69, 55-8(1926). R. E. T.

Developments in water softening. W. J. McLELLAND. *Contr. Rec.* 39, No. 52, 138-9, 163(1925).—Discussion of hardness in water, its effect on boilers and in textile industry and its removal by the Clarke or lime-soda process or by base exchange. Scale $\frac{1}{30}$ in. in thickness in boilers causes fuel loss of 1-10% and $\frac{1}{10}$ in. 2-20% depending on the compn. of the deposit.

R. E. THOMPSON

Water-softening developments—Rock Island lines. P. M. LABACH. *Am. Railway Eng. Assoc. Bull.* 27, No. 277-87(1925).—Detailed lab. expts. and results in the water-softening plant at Council Bluffs, Ia., and Estherville, Ia., indicate that less material can be used with better results and reduction in hardness if com. solns. of Na aluminate are added to the water sep. from the lime and soda ash.

R. C. BARDWELL

The softening of boiler waters. P. WIEGLEB. *Chem.-Ztg.* 49, 835, 856-7(1925).—W. describes 2 methods of water softening: (1) treatment with lime and soda or with Permutit and (2) a mech. method consisting of preliminary removal of suspended matter followed by evapn. and condensation of the boiler water by means of a series of evaporators, heat exchangers and condensers.

BEN. H. PETERSON

Water filtration and softening as applied to clay-products plants. H. M. MARSH AND W. J. McLELLAND. *Contr. Rec.* 39, 1161-3(1925).—Description of the water purification plant of Don Valley Brick Works, which consists of a settling and coagulation basin, mechanical pressure filter and zeolite water softener.

R. E. THOMPSON

Sounding bottle for taking samples of water in reservoirs. C. F. KLAPP. *Eng. News-Record* 95, 1083(1925).—A device for sampling water at varying depths is described and illustrated.

R. E. THOMPSON

Recording the hydrogen-ion concentration of potable water. H. C. PARKER AND J. R. BAYLIS. *J. Am. Water Works Assoc.* 15, 22-34(1926).—After a summary of the value of the H detn. in water treatment, a recording potentiometer is described, with W electrodes and the calomel cell, which is considered reliable and virtually fool-proof. As a result of such control, more uniform chem. treatment should be possible.

D. K. FRENCH

Micro-determination of the oxygen content of water. C. RISCH. *Biochem. Z.* 161, 465-7(1925).—A sample of water in a collector of known vol. is treated without exposure to air, with KI, NaOH and MnCl_2 . The container is closed and shaken for 1 hr. in the dark. Then the whole sample is removed and the I formed is titrated with $\text{Na}_2\text{S}_2\text{O}_3$, with starch as an indicator.

W. D. L.

Sterilization of water mains after laying. C. W. ABSHER. *J. Am. Water Works Assoc.* 15, 52-9(1926).—It is recommended that after laying new water mains they be sterilized with Cl to remove possible contamination from dirt and refuse. Liberal discussion supports such a suggestion.

D. K. FRENCH

Leakage tests of cast iron force main at Columbus, Ohio. J. C. PRIOR. *Eng. News-Record* 95, 870-2(1925).—Data are given on the leakage test of a new 36- and 42-in. cast iron main in Columbus. The max. leakage allowed in the contract was 528 gals. per 24 hrs. per in.-mile of pipe and av. leakage (cor. to standard pressure of 110 lbs.) during a 6-day test was only 87.3 gals. per 24 hrs. per in.-mile.

R. E. THOMPSON

Half of Lowell service pipes changed within 52 years. R. J. THOMAS. *Eng. News-Record* 95, 1041(1925).—Almost half of the 15,695 services installed since 1873, the first year after initial operation of the water works, have been changed because of (1) corrosive action of the original infiltrated and river supplies on wrought Fe pipe;

(2) action of later driven-well supplies on Pb and Pb-lined wrought Fe pipe, which caused Pb poisoning; and (3) leakage from Sn-lined wrought Fe pipe used in place of Pb-lined services. Cement-lined, tar-coated and rubber-treated pipes have been experimented with. Pb now predominates. Galvanized Fe has been employed during the past 10 years, but little confidence is placed on its durability. If the CO_2 was removed from the well supplies, Pb pipe would be as effective as brass. Considerable difficulty was formerly experienced because of incrustation of pipe of all materials, including Pb, with Fe and crenothrix, but this condition has been remedied by the installation of an Fe removal plant.

R. E. THOMPSON

Electrically welded water pipe: Tacoma's experience. W. A. KUNIGK. *Eng. News-Record* 95, 968(1925).—The experience in Tacoma, Wash., with elec. welded 30–60-in. steel pipe is reviewed and data on the difficulties encountered are given. Test bars cut from a no. of sections of finished pipe, all of which were hand-welded, developed joint efficiencies of 80–100%, all breaks occurring $1/8$ – $1/2$ in. from weld, except in 1 instance.

R. E. THOMPSON

Pipe steel shipped flat, then rolled and welded. C. A. P. DUFFIE. *Eng. News-Record* 95, 872–3(1925).—Illustrated description of the construction of a water pipe line (16,000 ft. of 30-in. and 26,000 ft. of 24-in.), steel for which was shipped flat and fabricated by oxywelding. Each length of pipe was tested prior to placing and only 3 joints were returned to the shop for rewelding. After testing the pipe was passed successively through hot alkali to remove grease, hot dil. H_2SO_4 to clean off scale, alk. neutralizing bath and hot rinse water. The pipe was then dried by means of gas flames playing on the outside, capped at each end, dipped in asphaltum and rolled in grit.

R. E. THOMPSON

Developments in sewage treatment and disposal during the year. H. P. EDDY. *Contr. Rec.* 39, No 52, 145–7(1925).—Progress in sewage treatment is reviewed, particularly as regards the activated-sludge process. Descriptions are included of the new activated sludge plants at Milwaukee and Indianapolis and of the “skimming-detritus tank” at Akron, O. and brief data on studies of the Engineering Bd. of Review of the Sanitary District of Chicago on disposal by diln. are given.

R. E. THOMPSON

The tri-cities' activated sludge plant at Alhambra, California. R. V. ORBISON, et al. *Eng. News-Record* 95, 714–6(1925).—The plant, serving Pasadena, South Pasadena and Alhambra, was put into operation in Jan., 1924. Including improvements since completed, necessitated by under-estn. of capacity required, it consists of 2 Dorr fine screens, 18 aeration tanks, 4 Dorr clarifiers, 11 sludge re-aeration tanks and 2 Oliver sludge filters. The av. flow treated is 6 m. g. d., and max. over 12 m. g. d. The effluent, which is chlorinated, is frequently sterile and bacterial count never exceeds 200 per cc. That portion not required for irrigation is discharged into the Rio Hondo, a tributary of the San Gabriel River. The Oliver filters reduce the water content of the sludge, after treatment with 7–9 lbs. of $\text{Al}_2(\text{SO}_4)_3$ per 1000 gals., from 99.2 to 80–84%, and the product is easily distributed over the sewage farm with an ordinary manure spreader. When dried to 10% moisture the sludge contains 7.79% total N_2 calcd. as NH_3 , of which 3.18% is water sol., and 3.94% H_3PO_4 . The cost of dewatering is 35¢ per 1000 gals. of sludge treated, and the product is worth 50–75¢ per ton as fertilizer. The total cost of the plant to date is \$532,000, or, on the basis of 55 gals. per capita per day, approx. \$4.70 per capita served. At 0.8–0.9¢ per kw.-hr., the power consumed costs \$11 per m. g. of sewage treated. Exclusive of interest, depreciation and sludge disposal, cost of operation is rated approx. at \$26 per m. g.

R. E. THOMPSON

Utilization of sewage sludge. LANGDON PEARSE AND S. A. GREELEY. *Eng. News-Record* 95, 836–7(1925).—The report deals mainly with the utilization of activated sludge, which has been found valuable as fertilizer. As a temporary measure Indianapolis is digesting activated sludge in tanks with primary sludge produced by fine screening and rapid settling. Imhoff, in the Ruhr District, Ger., and the Sanitary District of Chicago discharge excess activated sludge into the sludge chamber of Imhoff tanks, where it mingles with digesting primary sludge and is digested. Imhoff proposes to dispose of sludge in primary digestion tanks and to utilize the gases formed as power for compressing air required for the purification process. S, $\text{Al}_2(\text{SO}_4)_3$ and H_2SO_4 have been successfully employed in assisting coagulation of sludge prior to filtration or pressing. Chicago appears to secure the best results with $\text{Al}_2(\text{SO}_4)_3$, Houston with S, and Milwaukee with H_2SO_4 . Recent expts. at Chicago indicate that Fe_2Cl_6 is more efficient but more expensive. Artificial heating of sludge prior to dewatering has not been found necessary at Chicago and Indianapolis as at Milwaukee.

R. E. THOMPSON

Effect of temperature on rate of deoxygenation of diluted sewage. R. E. GREENFIELD AND A. L. ELDER. *Ind. Eng. Chem.* 18, 291–4(1926).—The biochem. O demand

in sewage dild. with aerated distd. water and incubated at from 2° to 6° shows a lag phase during the first few days, followed by a fairly rapid rise in the rate of deoxygenation. The deoxygenation is slow until a number of bacteria tolerant to low temp. develop. The formulas must be modified to suit the changed conditions. Sewage dildn. with distd. water shows an action different from that of polluted river water.

EDWARD BARTOW

Separate sludge-digestion experience. L. R. HOWSON. *Eng. News-Record* 95, 802(1925); cf. *C. A.* 19, 368. —Observations on sep. sludge digestion at Madison and Hartford, Wis., Lincoln, Neb., and Great Lakes, Ill., have demonstrated the ability of this system to accomplish efficient clarification and sludge reduction, producing a product which can be dried readily. It is possible that rate of digestion may be increased by application of artificial heat. Difficulties experienced in the past have been probably due to intermittency and incompleteness of sludge removal from the settling to the digestion tanks.

R. E. THOMPSON

Sewage disposal for city of 3,000 persons. F. M. VEATCH. *Eng. News-Record* 95, 589(1925). The recently constructed treatment plant at Holdrege, Neb., consists of an Imhoff tank and sludge bed. The tank, which was designed for a flow of 300,000 gals. per day, provides a settling period of 3 hrs. in parallel flow chambers and has a sludge digestion capacity of 2 cu. ft. per capita. The capacity of the sludge bed is equiv. to 1 sq. ft. per capita. Sprinkling filters and a settling tank will be added at a later date.

R. E. THOMPSON

What is the best sewage disposal system? F. W. HARRIS. *Contr. Rec.* 39, 926-8 (1925).—Comparison of sewage treatment on continuous percolating filters and by the activated sludge process. Expts. showed that the practical limit of purification of Shieldhall sewage was attained in 4 hrs. in a compressed-air activated-sludge unit and in 8 hrs. in a mechanical-agitation unit. Further expts. indicated clearly that the bio. intensity of activated sludge is greater with diffused aeration than with surface aeration, and that a degree of elasticity is provided in the former which is unattainable in the latter system.

R. E. THOMPSON

Sewer lining experiments for Los Angeles County. A. M. RAWN. *Eng. News-Record* 96, 18(1926).—Expts. are outlined which are being conducted in connection with the construction of the Los Angeles Co. Metropolitan sanitary sewer system to determine the most effective method of lining or treating concrete to protect it from the action of septic sewage.

R. E. THOMPSON

Intercepting sewers and disposal plant at Laramie, Wyoming. F. M. VEATCH. *Eng. News-Record* 95, 794-5(1925).—The new sewage treatment plant at Laramie consists of an Imhoff tank and sludge filters. The tank capacity is equiv. to a settling period of 1.5 hrs. and the sludge compartment was designed on the basis of 2 cu. ft. per capita, provision being made for a long storage period owing to climate. The sand beds for sludge drying have a capacity equiv. to 0.4 sq. ft. per capita. Each year's production of sludge will be dealt with by 3 dryings made during the summer months.

R. E. T

Purification of dairy wastes. F. DIENERT. *Lait* 5, 873-81(1925).—Casein should be recovered from the waste skim milk and buttermilk and used for cheese-making or as a stock feed. Chem. purification, spreading on the soil, bacteriol. decompn. and activated sludge processes are dealt with in turn as helping to render dairy sewage unobjectionable.

H. F. ZOLLER

Sanitary control in the development of ground water supplies. *Eng. News-Record* 95, 626(1925).—Code of principles formulated by the committee of Conference of State Sanitary Engineers and adopted at Louisville, Apr. 25, 1925, is given. The subjects dealt with include suction and gravity piping, collecting and storage reservoirs, cross-connections, wells, well supplies, purification, springs, mine water and infiltration galleries.

R. E. THOMPSON

Some specific factors responsible for pollution affecting analysis of water supplies. H. A. WHITTAKER. *Contr. Rec.* 39, 1025-6(1925).—Tabulation of factors influencing sanitary quality of water supplies.

R. E. THOMPSON

Stream pollution by acid mine drainage. R. D. LEITCH. *Bur. of Mines, Repts. of Investigations* No. 2725, 7 pp.(1926).—Mine water wastes from the Pa., Ohio and W. Virginia districts average 16-34 tons water per ton of coal mined. From representative analyses an est. of 200 grains H_2SO_4 per gal. is assumed. This pollutes the streams to a serious extent. Few attempts at disposal have been made. Allowing the waste to run over crushed limestone or marl has been tried with fair success. The use of Ba salts has been suggested. The expenses of both processes are almost prohibitive. Pennsylvania has organized a Sanitary Water Board to study the situation.

B. H. P

Atlanta (Ga.) now sells excess steam from refuse incinerator. H. J. CATES.

Eng. News-Record 95, 922-3(1925).—During a 4-month period reviewed only 36% of the entire steam production was used for plant operation and the remainder was sold. Nearly 1 lb. of steam was produced per lb. of refuse delivered to pits. Data on operation of the plant are given.
R. E. THOMPSON

Relation of storage water supply lakes to malaria. J. A. LE PRINCE. *J. Am. Water Works Assoc.* 15, 35-9(1926).—Suggestions are given for reducing the opportunities of storage reservoirs for being breeding places for the malaria-bearing mosquito.
D. K. FRENCH

Liability for water-borne disease. H. O. BLAIR. *J. Am. Water Works Assoc.* 15, 80-3(1926).—In 2 cases verdicts were rendered against a municipality supplying water for domestic and drinking purposes, after the facts were established that, through negligence, polluted water was allowed to pass into the city mains and deaths from disease were the result. Failure properly to inspect the water was considered negligence even though no guarantee of purity was given.
D. K. FRENCH

KERSHAW, G. B. Sewage Purification and Disposal. 2nd ed. Cambridge University Press. 361 pp 18s., by post 18s. 9d. Reviewed in *Munic. County Eng.* 76, 470(1925).

Softening water. R. G. TELLIER. U. S. 1,571,891, Feb. 2. H_2O to be softened is treated with extended surfaces such as a clay from Fall River Co., S. D., or other clay-like material contg. alkali metal silicate. U. S. 1,571,892 specifies prep. a H_2O -softening reagent by hardening and dehydrating clay-contg. compds. of the alkali metal or alk. earth metals, by heat treatment such as will produce a product permeable and resistant to H_2O , and then treating this product with NaOH soln. or NaCl soln.

Apparatus for purifying water by chemical treatment and sedimentation. A. W. ANDERSON and J. R. HICKOX. U. S. 1,571,225, Feb. 2.

Preventing and removing incrustation in boilers. J. SICHERT. Brit. 235,506, March 27, 1925. See U. S. 1,557,349 (*C. A.* 20, 84).

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Recent advances in science: Pedology. G. W. ROBINSON. *Science Progress* 20, 423-9(1926).—Review of recent work on soil chemistry and related subjects.

JOSEPH S. HEPBURN

Methods of mechanical analysis of soils. D. J. HISSINK. *Proc. Internat. Soc. Soil Science* [N. S.] 1, 137-56(1925).—A modification of the method of mech. analysis of soils consists of preliminary treatment of the sample with 20% H_2O_2 , boiling with 0.2 N HCl, and decantation of the finest fraction with 0.1% NH_4OH .
I. A. DENISON

Pedological chemistry. I. Alkalinity of the soil in relation to its lithological constitution. U. PRATOLONGO. *Atti accad. Lincei* [vi], 1, 238-43(1925).—Aq. solns. of calcite and aragonite satd. at the ordinary temp. have alkalinities expressed by p_H 8.0-8.2, whereas for hydromagnesite the value is 9.2. Investigation of the soly. curve of the system $CaCO_3-Na_2CO_3-H_2O$ at the ordinary temp. shows that the conditions for the formation and stability of gaylussite are the presence in the soln. of about 5% of Na carbonate and the presence of Ca carbonate; under such conditions the soil would be rendered completely sterile. For satd. solns. of brucite at the ordinary temp., the value of p_H is 10. Conclusion: The high degree of constitutional alk. (p_H 8.8-9.2) exhibited by certain soils is attributable to the presence, not of aragonite or calcite, but of hydromagnesite.
B. C. A.

The use of fertilizer in Java. S. N. QUAR. *Facts about Sugar* 20, 924-5(1925).—Requirements of different soils which are very deficient in N and the time and method of applying the fertilizer.
T. MARKOVITS

Problems of phosphate fertilization in France. V. P. KORSEKOV. Contributions Sci. Inst. Fertilizers (Leningrad), *Bull.* 12, 127-40(1924).—K. reviews the theories current in France on the influence of raw phosphates as a fertilizer, the influence of acid soils on phosphate utilization, the time period phosphates are effective in soils, composting of phosphates with org. materials, comparison of raw phosphates with other forms.
J. S. JOFFE

A solution of the phosphoric acid question for Germany. P. AD. PLAAS. *Z. Ver. deut. Ing.* 69, 490-500(1925).—The extensive and accessible phosphorite deposits of Russia offer great possibilities for exploitation to the mutual benefit of that country and Germany.

P. R. DAWSON

Phosphates in vegetation experiments. M. DOMONTOVICH. Contributions Sci. Inst. Fertilizers (Leningrad), *Bull.* 12, 141-75(1924).—An analysis is given of the exptl. work on the utilization capacity of various phosphates by different plants for the last 30 years. The reactions involved in respect to the effect of other ions on the soly. of phosphates are discussed. D. takes up the equations and derives the following consts. for the phosphates of Ca and H: (1) $[Ca^{++}]^3 \cdot [PO_4^{---}]^2 = K$; (2) $[H^+].[PO_4^{---}]/[HPO_4^{--}] = K_3$; and (3) $[H^+].[HPO_4^{--}]/[H_2PO_4^-] = K_2$. Taking Z for the total concn. of phosphates in a satd. soln. and assuming a complete dissociation of all the dissolved salts of phosphoric acid $Z = [PO_4^{---}] + [HPO_4^{--}] + [H_2PO_4^-]$. Expressing each one of the above values as a function of [Ca] and [H] one gets: $Z = \sqrt{K/[Ca]^3(1 + ([H^+]/K_3) + ([H^+]^2/K_2K_3))}$ (4). [Ca] is in the denominator and [H⁺] in the numerator and naturally with the increase of H the amt. of P₂O₅ in soln. increases. Side reactions may interfere but since there is no exact formula for the soly. of Ca₃(PO₄)₂ it may be expressed thus: $Z = f[H^+]/\phi[Ca^{++}]$. D. further discusses the influence of the reaction on the assimilation of P₂O₅, effect of Ca on the utilization of raw phosphates, role of root excretions, root absorption and reaction of root sap. The different plants vary in their ability to utilize raw phosphates. Many factors enter, such as the differential utilization of Ca, ability to take up P₂O₅ from dil. solns., formation of org. acids, phosphatides (combined with Ca), etc.

J. S. JOFFE

The significance of phosphates for Russian agriculture and the extension of the possibilities of utilizing raw phosphates. D. N. PRYANISHNIKOV. Contributions Sci. Inst. Fertilizers (Leningrad), *Bull.* 12, 19-30(1924).—P. discusses the possibilities of utilizing raw phosphate in different soils depending on various soil-plant reactions to decompose the phosphates and make them available. The soils adapted for such phosphate fertilization are grouped as follows: (1) The zone of debased chernozem, with the decay materials as a source of N and the unsatd. zeolite-like and humate compds. as the solubilizing agents. (2) The zone of blue lupines in the region outside of the chernozem with the atm. as source of N and lupine root excretions as the solubilizing agent. (3) The podzolized zone with the unsatd. complexes as the solubilizing agent and the atm. as a source of N. (4) The zone of peat with the org. acids of the peat as a solubilizing agent and the same peat as a source of N.

J. S. JOFFE

The significance of phosphates for the agriculture of the northern half of the chernozem soil. A. N. LEBEDIANTZEV. Contributions Sci. Inst. Fertilizers (Leningrad), *Bull.* 12, 66-90(1924).—L. analyzes the reactions responsible for the solubilization of raw phosphates in chernozem soils. He stresses the point of nitrification as an agent in solubilizing the insol. mineral constituents. In some chernozem soils with a definite alk. reaction the nitrification process locks up the phosphates, releasing some at first.

J. S. JOFFE

The use of phosphates according to the data of the various Experiment Stations. A. KRASINSKII. Contributions Sci. Inst. Fertilizers (Leningrad), *Bull.* 12, 91-126 (1924).—K. reviews the various studies on phosphate fertilization in the different Expt. Stations on soils of various chem. compn.

J. S. JOFFE

Phosphates and peat. F. PERETURIN. Contributions Sci. Inst. Fertilizers (Leningrad), *Bull.* 12, 205-9(1924).—P. presents a discussion and exptl. evidence on the influence of peat on the soly. of raw phosphates. Peat seems to be an effective means to convert the insol. phosphate into available form.

J. S. JOFFE

The soil and raw phosphates. A. N. SOKOLOVSKII. Contributions Sci. Inst. Fertilizers (Leningrad), *Bull.* 12, 191-204(1924).—S. analyzes the dynamics of soil processes and their influence on the soly. of raw phosphates. It is a comprehensive theoretical discussion of the state of satn. and unsatn. of soils, the processes of decay of org. matter and the possible influence of these on the soly. of raw rock phosphate.

J. S. JOFFE

The solubility, decomposition and evaluation of the various forms of phosphoric acid and phosphatic fertilizers. K. SCHARER AND A. STROBEL. *Z. angew. Chem.* 38, 953-8, 988-92(1925).—A discussion of the nature of various phosphates, as to their soly. and availability to different plants, together with methods for evaluating them in these respects, as well as for estg. available P₂O₅ in soils.

P. R. DAWSON

Radioactive fertilizers. HANS EGNER. *Kungl. Landb. Akad. Handl. Tidskr.* 64, 737-62(1925).—E. concludes after an extensive examn. of existing literature relative

to influence of radioactive substance on growth and also making several trials with radioactive fertilizers, that nothing is to be gained by using radioactive preps. for fertilizing purposes. A bibliography on trials with radioactive fertilizers is given.

C. O. SWANSON

Manufacture of fertilizer urea on a tonnage basis. R. S. MCBRIDE. *Chem. Met. Eng.* **32**, 791-3(1925).—A description is given of the Lindholm process for manuf. of urea from CaCN_2 , as in operation in a pilot plant at the Niagara Falls Works of the Union Carbide Co.; some technological and economic aspects are discussed; and emphasis is placed upon the high efficiency of urea as a source of fertilizer N.

P. R. DAWSON

Fertilizer experiments: Methods of application and effect on germination, early growth, hardness, root growth, lodging, maturity, quality and yield. EMIL TRUOG, H. J. HARPER, O. C. MAGISTAD, F. W. PARKER AND JAMES SYKORA. *Univ. of Wis. Research Bull.* **65**, 55 pp.(1925).—The osmotic pressure of the cell sap of the sprouts of certain plants was: corn 7.180, rye 7.072, field peas 6.837, navy beans 6.628, oats 6.573, cowpeas 6.025, potatoes 6.150, cucumbers 3.779 and muskmelons 3.225 atms. Field crops were grown in sterile sand cultures, with various salts supplying the N. In every case as good and in most cases much better growth was obtained with NaNO_3 than with various NH_4 salts. Under these conditions the NH_4 radical seems to be toxic to oats. It is pointed out that the benefits derived from NH_4 salts in the field are due at least in part to conversion to nitrates by bacteria. The addn. of about 200 lbs. per acre of KCl or K_2SO_4 to Carrington silt loam increased the H-ion concn. from pH 5.71 to 5.15 and 5.40, resp., but when added to acid peat soil reduced it from 4.58 to 4.82 and 4.66, resp. A satisfactory explanation for the latter cannot be given. The addn. of large quantities of acid phosphate to Carrington silt loam greatly stimulated nitrification in it. A bibliography of 20 citations is appended.

A. I. MEHRING

The influence of the degree of soil moisture on the yield and composition of tobacco. A. V. OTRYGANIEV. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia)* **1924**, No. 22, 1-32.—Pot expts. are reported on the effect of moisture content on the growth and compn. of tobacco in light sandy and heavy clay (chernozem) soils. The lower moisture content in the sandy soils brought about a lower N content in the plants. The addition of fertilizers increased the nicotine content, total ash and total N. In the clay soils a concn. of salts in the soil soln. under conditions of a low moisture content increased the N content of the plants. The best yields were obtained on both soils when the moisture added equaled 60% of the total moisture-holding capacity of the soil. A French résumé is found at the end of the article.

J. S. JOFFE

The influence of nitrogen nutrition on the development and quality of tobacco. A. V. OTRYGANIEV. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia)* **1924**, No. 21, 1-18.—An increase in nitrogenous fertilizers increases the yield of tobacco. Parallel with the increase in yield goes the increase in nicotine content (0.31% without N and 0.77% with 1 g. N per pot (8000 g. of sand) and 2.59% with 2 g. N). The carbohydrate content falls from 24% with 1 g. N to 8.59% with 2 g. N. An extensive résumé in French is given at the end of the article.

J. S. JOFFE

Manganese and plant growth. J. S. MCHARGUE. *Ind. Eng. Chem.* **18**, 172-5 (1926).—Mn functions in the synthesis of chlorophyll and C assimilation in plant growth. One of the first signs of the lack of Mn in the growth of plants is the failure to synthesize chlorophyll. The young leaves and branches as they put forth are chlorotic and do not attain a normal green color. Their starch and sugar contents are less than in normal foliage grown in the presence of Mn. No other one of the common elements will replace the function of Mn in plant growth. It plays a role of importance equal to that of Fe in the synthesis of chlorophyll. It is pointed out that most chemicals contain small quantities of Mn and its effect in plants can only be demonstrated by using Mn-free chemicals and app. in culture expts.

J. J. SKINNER

Carbon dioxide as fertilizer. HENRIK LUNDEGÅRDH. *Kungl. Landt. Akad. Handl. Tidskr.* **64**, 710-26(1925).—L. used a greenhouse 30 m. long and 3 m. wide, divided into four parts, one of which was used as a control. To the other parts CO_2 was added in different amounts to growing cucumbers, beans, tomatoes and sugar beets. CO_2 was detd. in the air daily. The air of the control compartment contained an av. of 0.623 mg. CO_2 per 1000 cc. air. In the part which contained 0.808 mg. CO_2 per 1000 cc. air, the increase in the growth of beans was 79%, tomatoes, 6.7% and cucumbers from 12.4 to 36%. When the proportion of CO_2 was increased from 100 to 113.2 the proportional increase in the growth of sugar beets was from 100 to 138, and when the proportion of CO_2 was increased from 100 to 127.1 the proportional increase in the growth of sugar beets was from 100 to 155. Field trials were also made and while the

conditions were not under exact control, the results were pc depends on intensity of light, the CO_2 content of the air ar

Iodine fertilizing and iodine feeding. TH. VON FELL 210-24(1925).—The leaves of sugar beets grown in soils fert amts. of iodide, more, however, than the roots. The additi soil but little with iodide, as the KI was largely oxidized t constituents of the soil. The milk of cows fed on I-rich bec distinct increase in I.

A method for testing out dry (powder-form) fungicidal agents (for grain) in the laboratory. FRIEDRICH PICHLER. *Chem.-Ztg.* 49, 879-80(1925).—Specially prepd. boxes are filled with earth, planted with inoculated grain, covered with earth to a known depth, and kept in a thermostat at $16-18^\circ$. The grain is inoculated by shaking a known wt. of it with 1% its wt. of smut in a stoppered flask for 2-3 min. The smut spores must be from a recent harvest, and of good germinating quality. Five-g. samples of inoculated grain are placed in small flasks, treated with known amts. of the prepn. under investigation (with shaking) for 10 min., and 20 grains from each sample then planted in the boxes. Runs are made in triplicate, dry, moist and very moist; microscopie examns. are made of the grain at intervals up to 10 days and the germinating power of the grain itself is noted in addition. Smut spores germinate in about 5 days. Results are comparable to those obtained in practice with the same smut-preventives.

W. C. EBAUGH

The application of plant-protecting agents in dust form. E. RIEHM. *Z. angew. Chem.* 38, 1032-4(1925).—A discussion of the advantages and disadvantages of the application of insecticidal and fungicidal dusts, with special reference to recent German and American com. products.

P. R. DAWSON

California petroleum insecticides. Laboratory and field tests. G. P. GRAY AND E. R. DE ONG. *Ind. Eng. Chem.* 18, 175-80(1926).—Tests were made of 30 petroleum distillates to det. to what extent the various phys. tests are significant in detg. the toxicity of an oil to vegetation. The toxicity of the oils tested appeared to increase roughly in proportion to the amt. of unsatd. compds. present. The percentage of the oil sol. in 37 N H_2SO_4 may be used to est. the amt. of unsatd. compds. in an oil and is suggested as a useful guide in judging toxicity. The ability of an oil to penetrate plant tissue must be taken into account. Conclusion: Phys. tests alone are inadequate.

J. J. S.

Combating crop diseases with chemicals. A. KLAGES. *Z. angew. Chem.* 39, 3 10(1926).—A review with statistics of crop diseases and methods of grain treatment with especial reference to Hg compds.

MARY JACOBSEN

Effectiveness of calcium cyanide in poisoning the pocket gopher, *Geomys bursarius* (Shaw). F. L. WASHBURN AND C. E. MICKEL. Minnesota Agr. Expt. Sta., *Tech. Bull.* 27, 14 pp.(1925).—The use of Ca cyanide in poisoning gophers was no more effective on clay soils than sandy ones and it was found to be more expensive than the use of poison baits.

J. J. SKINNER

Sheep dips. Their composition and analysis. J. S. REMINGTON. *Ind. Chemist* 1, 525-8(1925).—The chief parasites to be killed are the scab mite, the tick, the ked, the maggot and the red louse. Total immersion is necessary in a soln. that will kill all the above, and that will not injure the sheep or the wool. The dips may be classified as (I) Dry yellow powders composed chiefly of S and $\text{Na}_3\text{AsO}_4 \cdot 12\text{H}_2\text{O}$ with small quantities of Na_2HAsO_3 and As_2S_3 . (II) Soft paste dips composed of the same materials as (I) but contg. in addn. resinous soft soap and sometimes coal tar and creosote. (III) Black viscous liquids composed of creosote and soft soap. Analysis of group I: (1) moisture at 105° , (2) S by extn. with CS_2 in a Soxhlet app., (3) As compds. 5 to 10 g. is heated with satd. NaHCO_3 to dissolve As_2S_3 , the filtrate is acidified with dil. HCl and any pptd. As_2S_3 weighed on a tared filter. The filtrate is made up to 300 cc., 100 taken and As^{V} detd. as $2(\text{MgNH}_4\text{AsO}_4) \cdot \text{H}_2\text{O}$. 25 cc. is now taken and As^{III} detd. by titration with 0.1 N I_2 and Na_2HAsO_3 calcd. Group II: (1) 50-100 g. is heated to 170° in a retort and the distd. H_2O is measured in cc. (2) 100 g. is ignited with concd. H_2SO_4 . The wt. of $\text{K}_2\text{SO}_4 \times 4.299$ gives the wt. of resinous potash soap. $\text{K}_2\text{SO}_4 \times 3.862$ gives the wt. of resin. From the wt. of Na_2SO_4 the arsenite is calcd. (3) S and arsenate are detd. as in group I. The creosote is obtained partly along with the S. Weigh S + creosote and det. the S by oxidation and pptn. as BaSO_4 . The resin, fatty acids and phenols are obtained with the As_2O_3 . Group III: A modification of the method on p. 262, Vol. II, Part II of Allen's Comm. Org. Anal. is given. Results of a number of analyses for each group are given. For further particulars the original must be consulted.

E. G. R. ARDAGH

Removing SiO_2 from ore leaches [for fertilizer manufacture] (U. S. pat. 1,571,054) 18.

Fighting Rust With Sublimed Blue Lead; an assemblage of facts concerning the properties and uses of sublimed blue lead. Edited by Eagle-Picher Lead Co. Chicago: The Eagle-Picher Lead Co. 82 pp.

Fertilizer. BADISCHE ANILIN & SODA FABRIK. Brit. 236,494, March 14, 1925. KNO_3 215, $(\text{NH}_4)_2\text{HPO}_4$ 190 and dry urea 70 parts are used together and may be pressed into tablets or cakes.

Phosphatic fertilizer. RHENANIA VEREIN CHEMISCHER FABRIKEN AKT.-GES. Brit. 235,860, June 23, 1921. A mixt. of natural phosphate, alkali sulfate or chloride, SiO_2 and an alk. earth compd. such as CaCO_3 is heated in the presence of steam to $900\text{--}1000^\circ$. Fe oxide or Al oxide may be used instead of SiO_2 and citrate-sol. phosphate is produced.

Fertilizer and insecticide. A. G. BRYON. Brit. 235,802, Jan. 22, 1925. A powd. mixt. of lime, NaCl and soot, with or without poultry manure.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

The production of hydrogen by microorganisms. A. C. THAYSEN. *Chem. Age* (London) 14, 28(1926).—By the use of a bacterium belonging to the *Amylobacter* group, starch has been converted into a mixt. of 10.77% of acetone, 25.07% of butyl alc., 62.61% of CO_2 , 1.6% of H_2 , and 1.80% of org. acids. The H_2 is readily sepd. from the CO_2 and possesses high purity. Being a waste product, its cost of production lies in cost of collection and purification. During the World War it was shown that 1000 cu. ft. (28.3 cu. m.) could be produced for 25¢.

W. H. BOYNTON

Influence of certain colloids upon fermentation. II. R. GREIG-SMITH. *Proc. Linnean Soc. N. S. Wales* 50, 341–58(1925); cf. *C. A.* 19, 1321.—Colloidal SiO_2 induced a more rapid production of CO_2 in the fermentation of sucrose by distillery yeast. Asbestos and SiO_2 hastened the inversion of sucrose by yeast, and SiO_2 accelerated the fermentation of dextrose. Wood charcoal, talc, kaolin, fuller's earth, asbestos, kieselguhr, French chalk and $\text{Fe}(\text{OH})_3$ hastened the slow fermentation of dextrose. The differences in the relative amts. of fermented material were not so great as when dealing with bacteria, but were sufficiently marked to show that the yeasts as well as bacteria have their fermentative activities accelerated by the presence of certain minerals and other colloids and that the isolated enzymes are not influenced by the same colloids.

L. W. RIGGS

The fermentation of cacao shell. A. CHURCHMAN. *J. Soc. Chem. Ind.* 44, 540–2T(1925).—Cacao husks were hydrolyzed under pressure with dil. H_2SO_4 and the ext. was neutralized with CaCO_3 and filtered. The filtrate was fermented with *Saccharomyces cerevisiae*, and the alc. production detd. The max. yield of alc. (2.5%) was too low to be commercially valuable.

T. S. CARSWELL

Hop extractor. ANON. *Apparatebau* 38, 4(1926).

J. H. MOORE

The chemical manufacture of alcohol (GIROD) 10.

Carbonating beer or other beverages. J. L. BAKER. Brit. 235,646, March 20, 1924. "Aerated" beverages are "revivified" by adding to them a small quantity of "supergassed" beverage. An app. is described.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Studies on a plant from the Congo, belonging to the species of nitragyne (Rubiaceae) and its alkaloid, followed by some observations on gelsemine and yohimbine. MICHIELS AND LEROUX. *Bull. acad. roy. med. Belg.* [5], 5, 403–18(1925).—The bark of a tree from the Congo, closely resembling *Uncaria gambier*, contains 1% of an alkaloid, crystallizing from alc., m. 243° , the hydrochloride of which is pptd. by the reagents of

Bouchardat, Mayer and Dragendorf. With concd. $\text{H}_2\text{SO}_4 + \text{K}_2\text{Cr}_2\text{O}_7$ it yields a red color changing to green and a violet color with reagent of Mandelin. The reactions of this unknown alkaloid resemble to a certain degree those of gelsemine and yohimbine.

R. BEUTNER

The arsenobenzenes, their composition, their toxicity and their control. DE MYTTEAERE. *Bull. acad. roy. med. Belg.* [5], 5, 433-69 (1925).—De M. discusses, partly in a polemical way, the following publications which concern the analysis of arsenobenzene: Valeur and Launoy (*C. A.* 19, 1756), P. L. Moreau and Pontoizeau (*Arch. Med. Pharm. Militar.* Dec., 1924, 745), and Kahl, Tomczynski and Weil (*C. A.* 19, 1455). The deviations observed by these authors are due to a failure to comply exactly with the directions of De M. Arsenic should be between 19 and 21%; the ratio As:N should be between 5 and 5.6; the index D M should not be higher than 12. To det. As decompose 0.2 g. of the substance by means of concd. H_2SO_4 , oxidize to quinquevalent As and titrate iodometrically. Det. N by the Kjeldahl method. To det. the D M index dissolve 1 g. of the substance in 90 cc. H_2O and 10 cc. dil. AcOH, heat on a water bath until pptn. occurs and then 10 min. longer. After 12 hrs. filter, warm the filtrate to 60° , add 5 cc. HCl and sat. the soln. with H_2S at 60° . Filter and wash the ppt. to neutral reaction; take up in $(\text{NH}_4)_2\text{CO}_3$ soln., filter, evap. the soln. on a sand bath until all NH_3 has disappeared, add 10 cc. H_2O and 10 cc. 50% H_2SO_4 . Det. As in this soln. as described above; the no. of cc. of 0.01 N I soln. used is the D M index. A modification of Macallum's detn. of the partial and of the total reducing power is described.

R. BEUTNER

A comparative study of various insulin preparations. B. SYBRANDY. *Nederland. Tijdschrift Geneeskinde* 69, II, 2776-81 (1925).—The lowering of the glucose content of the urine in 3 patients with heavy diabetes is used to standardize a number of insulin preps. The action of the same prepn. in different patients is not parallel, however. The lowering of the acetone in the urine is not proportional to the lowering of the sugar content. Insulin seems to contain one factor acting on the glucose and another one on acetone.

R. BEUTNER

Desiccated gonadal substances. H. SHARLIT AND J. SAMET. *Med. J. and Rec.* Feb. 4, 1925 (reprint), 5 pp.—In the prepn. of gonadal substances for therapeutic purposes, care must be taken to avoid liquefaction of the fats, oxidation and reduction reactions and hydrolytic cleavage. This necessitates rapid desiccation at low temp. and pressure, and in presence of a min. of circulating air. Analysis of com. prepus. shows that these conditions are not always observed. In some cases defatting is resorted to with the object of facilitating pulverization.

B. C. A.

Color reaction of adrenaline. R. GUYOT. *Bull. soc. pharm. Bordeaux* 63, 214-6 (1925).—If 2 drops of a soln. of NaVO_3 (NaVO_3 0.5 g., NaOH soln. 20 drops, distd. H_2O 10 cc.) and 2 drops of NaOH soln. are added to 2 drops of adrenaline soln. in 100 cc. of distd. H_2O , there will develop a pink coloration changing to red. By this reaction, as little as 0.00001 g. of adrenaline can be detected.

A. G. DUMÉZ

Conservation of solution of arsenic triiodide. R. GUYOT. *Bull. soc. pharm. Bordeaux* 63, 217-22 (1925).— AsI_3 when dissolved in H_2O dissociates into As_2O_3 and HI. The HI is acted upon by O and free I is deposited in a short time. To overcome this, G. proposes that the freshly prepd. soln. be neutralized with NaOH soln. This really converts the AsI_3 into arsenite, viz.: $\text{AsI}_3 + 4\text{NaOH} = \text{NaH}_2\text{AsO}_3 + 3\text{NaI} + \text{H}_2\text{O}$. The arsenite soln. appears to be stable.

A. G. DUMÉZ

Alteration of glucose serum in ampules due to bacterial action. R. GUYOT. *Bull. soc. pharm., Bordeaux* 63, 222-3 (1925).—Decompn. of a soln. of glucose contained in ampules and sterilized in an autoclave at 105° for 20 min. was observed. The soln. was contaminated with *B. amylobacter*, the spores of which are able to withstand this temp.

A. G. DUMÉZ

Extemporaneous preparation of mercurial ointment. L. DUCASSE. *Bull. soc. pharm., Bordeaux* 63, 223 (1925).—The following are the ingredients used in this ointment: HgO (red) 0.60 g., balsam of Peru 2.0 g., soln. of H_2O_2 (12 vol.) 10 g., lanolin 50 g., vaseline 38 g., Hg (metal) 100 g. In a mortar of suitable size, triturate the HgO with the balsam, then pour on the Hg and incorporate gradually the previously mixed lanolin and vaseline. Titurate until the Hg has been extinguished.

A. G. DUMÉZ

Ash content of plantain (*Plantago lanceolata*). B. PATER. *Pharm. Monatshefte* 6, 217-8 (1925).—Notable among the findings reported are 38.8% K_2O in the ash of the entire plant and 39.2% for the ash of the aq. ext. (corresponding values for *P. major* being 39.4 and 38.1%), while SiO_2 is given as: total 1.35, insol. 0.91% (*P. major* total 2.16, insol. 1.41%).

W. O. E.

Oil of *Bifora radians* M. B. B. PATER. *Pharm. Zentralhalle* 67, 17-8 (1926).—

The green plant, which possesses an unusually marked odor and a habit not unlike coriander, yields a light green strong smelling oil (0.124%) having the consts.: d_{4}^{15} 0.870; α_D -0.2; n_{20} 1.4624; insol. in 25 parts of 80% EtOH; acid no. 23.8; sapon. no. 53.3; ester no. 29.5. The possible use of this oil in minute amt. in perfumes is suggested.

W. O. E.

Estimation of quinine. LUDWIG DAVID. *Pharm. Ztg.* **71**, 26-8(1926).—In estg. quinine in cinchona bark the following procedure is recommended: In a Jena Erlenmeyer flask provided with a rubber stopper weigh accurately 17 g. of 1% HCl, add 1.7 g. of the powdered sample (sieve No. VI), heating and stirring the mixt. $\frac{1}{2}$ hr. on the H₂O bath, apply the stopper after removal from bath and stir from time to time over a period of $\frac{1}{2}$ hr. Cool and weigh, replacing any loss in wt. with 1% HCl. Pass the liquid through an 8-cm. filter into a dry flask, finally pressing out the filter with the fingers. Transfer 10 g. (1 g. of the bark) of the filtrate to a 50-cc. beaker, stir in 10 drops of 0.1 N NaOH followed by 10 cc. of 20% Na₂HPO₄ soln., allowing the mixt. to stand 1 hr. with occasional stirring. Collect the ppt. on a 7-cm. filter, washing both beaker and ppt. in rotation with four 2.5-cc. portions of dil. Na₂HPO₄ soln. (1 cc. of 20% Na₂HPO₄ soln. + 9 cc. H₂O). Remove all traces of ppt. clinging to the beaker with a moist strip of filter paper (about 2.5 cm.), add to main ppt., transfer to a 50-cc. flask with large mouth, add 4 cc. 20% NaOH soln., close with cork and shake 1 min. vigorously, add 6 g. NaCl and again shake. Now add two 15-cc. portions of Et₂O, stopper well and shake vigorously 20 min. After $\frac{1}{2}$ hr. pipet 15 cc. of the clear Et₂O soln. into a 50-cc. Erlenmeyer flask, expel the solvent, add to the dry residue two 3-cc. portions of Et₂O, expelling the solvent each time after such addn., then dissolve the dry residue in 20 cc. neutral EtOH and titrate with 0.1 N HCl in the presence of laemoid (factor 0.0324) using a microburet for the operation and multiplying the no. of cc. of acid expended by 6.58 to obtain the %.

W. O. E.

Preparation of hydrogen sulfide in the pharmaceutical laboratory. F. OSWALD. *Pharm. Ztg.* **71**, 39(1926).—After reference to the customary use of FeS and Na₂S in the generation of H₂S the advantages of thioacetic acid for this purpose are pointed out, particularly in the absence of the erstwhile commonly available app. of Kipp and of Woulff.

W. O. E.

Notes on the U. S. P. X. J. W. ENGLAND. *Am. J. Pharm.* **98**, 37-52(1926).—A study of some of the more striking changes.

W. G. GAESSLER

Some anomalous tensions. D. W. HORN. *Am. J. Pharm.* **98**, 53-8(1926).—The results of recent measurements made with the duNouy app. upon the superficial tensions of aq. solns. of soaps, tannin, ext. of licorice and saponin are given in a table and discussed.

W. G. GAESSLER

A century of alkaloids. A. D. THORBURN. *J. Chem. Education* **2**, 886-99(1925)

E. H.

Spectrophotometric analysis of commercial insulin. E. J. BALDES AND S. F. ADAMS. *Am. J. Physiol.* **74**, 309-13(1925).—Com. and lab. specimens of insulin show no absorption bands in the visible spectrum. The curves obtained by plotting light transmission as a function of λ may be used for the detn. of insulin, as with the present prepn. methods the quantities of yellow pigment and insulin seem to run parallel.

MARY JACOBSEN

A new method of assaying the potency of the female sex hormone based upon its effect on the spontaneous contraction of the uterus of the white rat. R. T. FRANK, C. D. BONHAM AND R. L. GUSTAVSON. *Am. J. Physiol.* **74**, 395-9(1925).—An exact assay method of the female sex hormone is afforded by the slowing of the spontaneous uterine contractions under the action of sufficient hormone quantities. Potent exts. of follicular fluid, corpus luteum and placenta have the same effect.

MARY JACOBSEN

Studies on the ultrafiltration and electro dialysis of insulin. T. C. TAYLOR, C. E. BRAUN AND E. L. SCOTT. *Am. J. Physiol.* **74**, 539-65(1925).—The active principle of insulin can be ultrafiltered through collodion membranes of high and low permeability without loss of activity and with the N content unaltered. By electro dialysis at pH 3.6 (not at the isoelec. point: 5.6) insulin prepn. are sepd. into: (1) a sediment with doubled activity which gives protein reactions and contains S but no P and (2) a soln. nearly inactive showing protein reactions and contg. neither S nor P. When treated with equal vols. of 25% H₂SO₄ and 95% EtOH the sediment gives a microcryst. product.

MARY JACOBSEN

The presence of insulin in desiccated beef pancreas. VICTOR ROSS. *Am. J. Physiol.* **74**, 579-82(1925).—It was established by expts. on white rats that beef pancreas desiccated at (max.) 40° and 15 mm. contains approx. as much insulin as the corre-

sponding amt. of fresh material. The material is suitable as a standard for comparing insulin yields in different prepsns.

Ethereal oils of tobacco. A. SCHMUCK. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia)* 1924, No. 19, 1-16; cf. *C. A.* 19, 1031.—The ethereal oils were sepd. by steam distn. and extd. with ether. No relation was found to exist between the oil content and other org. constituents. The ethereal oils may be characterized by their physico-chem. const., which vary with the varieties of tobacco. In Dewbek (a high-grade cigaret tobacco) the sp. gr. is 0.8411, while in Bakoon (a poor grade of pipe tobacco) it is 1.0306. The sapon. no. of the former is 128.64, of the latter 58.79. From the ethereal oils of Dewbek furfural was isolated. Whether the furfural was present in the plant originally, or was formed in the process of steam distn. could not be detd. The oil was divided into 3 fractions; (1) boiling at 80° comprises $\frac{1}{2}$ of the oil, (2) boiling at 120°, a very small fraction and (3) is the residue, which upon distn. in a vacuum becomes resinous; this fraction crystallizes easily. Various tests with the first fraction indicates that it is an ester of butyl alc. The second fraction behaves like hexyl formate. The third fraction in its reactions resembles diallylcarbinol.

J. S. JOFFE

A study of the resins and aromatic substances of tobacco. A. SCHMUCK. *Inst. of Exptl. Tobacco Culture, Krasnodar (Russia)* 1924, No. 20, 5-13.—Hot benzene exts. from tobacco the resins with some traces of nicotine, leaving behind the carbohydrates, tannins, glucosides. The tobacco is then extd. with petroleum ether, Et_2O and finally with alc. From 100 g. dry tobacco the following amts. were extd.: with benzene 6.87 g., with petroleum ether 0.09 g., with Et_2O 3.65 g., with alc. 22.88 g. The benzene soln. was evapd. on a water bath and the residue was treated with ether; 0.46 g. of the substance did not dissolve. This insol. substance has a pleasant weak aromatic odor, and upon burning forms aromatic products which have an irritating influence on the mucous membranes of the respiratory organs. In H_2O , ether and petroleum ether it is insol.; dissolves with difficulty in hot EtOH and crystallizes upon cooling. It decolorizes Br water, forming a light yellow Br compd., m. 118-120°. The original substance m. 86°. The reaction is neutral; it contains no N or ash. It seems to be an unsatd. compd., $\text{C}_9\text{H}_{16}\text{O}_2$. It is insol. in acids or alkali. The compn. corresponds to the general formula $\text{C}_n\text{H}_{2n-2}\text{O}_2$. The next fraction (II) of the benzene ext., equiv. to 0.41 g., is a free acid, $\text{C}_{24}\text{H}_{40}\text{O}_6$, similar in its properties to kentukilic acid ($\text{C}_{23}\text{H}_{40}\text{O}_6$), isolated by Haid. The next fraction (III) is an acid combined with the ether corresponding to the formula $\text{C}_8\text{H}_{12}\text{O}_2$; then comes (IV) a resin alc. $\text{C}_6\text{H}_{10}\text{O}$ and (V) the phenols. Fractions III, IV and V comprise 5.03 g. of the benzene ext. and may be classed under the name of resin ether. The alc. ext. after distg. the alc. gave a thick mass weighing 22.89 g. An ether ext. of this mass gave a green coloration. The residue was dissolved in H_2O , from which upon standing there sepd. 1.4 g. of a brown cryst. ppt., m. 140°. It is hardly sol. in H_2O , ether, CS_2 , petroleum ether; is sol. in MeOH ; it contains no N and gives no ash; when burning it gives a pleasant smoke. With HCl upon heating it reduces Fehling soln. From its coloration properties it seems to be a glucoside, $\text{C}_{22}\text{H}_{36}\text{O}_{14}$. The petroleum-ether ext. gives 0.0978 g. of a substance without any aromatic odor. The Et_2O ext. gives 3.6561 g. of a substance with a sharp pungent odor resembling that of formic and acetic acid. The substance is volatile and complex in nature; has not been studied.

J. S. JOFFE

The distribution of resins in tobacco. N. A. TRANKVILITSKAYA. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia)* 1924, No. 20, 14-8.—This is a study of the quant. distribution of the various resin fractions, as outlined by Schmuck (preceding abstr.), in several varieties of tobacco.

J. S. JOFFE

An attempt to determine the character of the carbohydrate complex of tobacco. A. SCHMUCK. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia)* 1924, No. 20, 19-22.—In the variety of tobacco Dewbek were found no starch, dextrin 1.68%, complex and simple sugars 9.58%, of which 8.35% reduce Fehling soln. The author gives two methods for extg. the sugars and the standard procedure for their detn.

J. S. J.

The content of various forms of carbohydrates in tobacco. V. S. BALABOOCA. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia)* 1924, No. 20, 23-9.—Detns. were made of cellulose, hemicellulose (especially pentosans) and the carbohydrates sol. in water on 6 varieties of tobacco before and after fermentation. No starch was found. The better varieties of tobacco give a higher carbohydrate content. The cellulose content is about the same in all varieties. The methods of analysis are given.

J. S. J.

The chemical composition of some varieties of Russian tobacco. K. J. KREVS. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia)* 1924, No. 23 1-26.—Analyses are given for hygroscopic moisture, total N, nicotine, NH_3 , protein, glucose, starch and dextrin, total carbohydrates, acetic, oxalic, citric and malic acids, cellulose, pentosans,

resins, gums and fats, N_2O_5 , amido compds., pure ash, SO_3 . In the ash detns. were made of SiO_2 , Cl, SO_3 , P_2O_5 , Fe_2O_3 , MnO , CaO , MgO , K_2O , Na_2O . Also there are given amts. of K_2O , P_2O_5 , CaO , N and Cl taken up by the crop. Results on various soils with and without fertilizers are given in other tables. J. S. J.

The chemical composition of tobacco and methods for its investigation. A. SCHMUCK. *Inst. Exptl. Tobacco Culture, Krasnodar (Russia), Monograph 1924*, 156.—The work reported is a result of many investigations on the compn. of tobacco conducted at the Institute. The scheme followed in the tobacco analyses was as follows:

- | | | |
|---|---|-------------------------------|
| (1) Valuable component fractions | { | Alkaloid group < Nicotine |
| | | Ether alkaloids |
| | { | Etheral oils |
| | | Resins |
| (2) Indifferent fractions | { | Carbohydrates |
| | | Cellulose |
| | | Oxides |
| | | Tannins |
| (3) Fractions influencing tobacco negatively | { | Proteins |
| | | Several non-protein N compds. |
| (4) Substances influencing the burning of tobacco | { | Ash |

The chapter deals with (1) The alkaloid group in tobacco; methods of detg. nicotine; (2) aromatic substances, methods of detg. the etheral oils and resins of tobacco; (3) ash; (4) carbohydrates; (5) acids; method of detg. them; (6) N compds.; methods of detg. them; (7) chem. compn. of tobacco seeds; (8) compn. and investigations of tobacco smoke; (9) the objective classification of tobacco. J. S. JOFFE

Measurement of the effect of insulin. H. LANGECKER AND W. STROSS. *Biochem. Z.* **161**, 295-336 (1925).—The deviation from the av. in the detn. of the blood sugar values of normal rabbits is 11.5 mg. per 100 cc. whereas with rabbits treated with insulin, it is about 20 mg. In addn. there is an individual variation in the response of rabbits to insulin treatment which cannot be standardized. Mice show similar variations. A new unit is proposed, it is obtained by dividing the cramps-producing dose of the standard prepn. by what the dose should be and multiplying by the minimal cramps-producing dose of the unknown solns. for the individual. The conditions for working out the unit are described. It is more const. than the present accepted unit. W. D. L.

Analyses of organotherapeutic powders; their content of total, lipoidic and nucleic phosphorus. M. JAVILLIER, H. ALLAIRE AND MME. HINGLAIS-GROC. *Bull. sci. pharmacol.* **32**, 641-59 (1925).—Total P was detd. by a semi-microchem. method of Hinglais-Groc (thesis) and of Copaux (cf. *C. A.* **16**, 219). Lipoid P was extd. from the tissues by 95% alc., preferably in a Kumagawa app. (Soln. A), and was followed by a short extn. with ether (Soln. B). From Soln. A the alc. was distd. under reduced pressure and the residue was dried by 2 washings with 85% alc. and one washing with abs. alc. The dehydrated residue was taken up with anhyd. Et_2O , which dissolved the lipoidal fraction in part, the remainder being dissolved in anhyd. C_6H_6 (cf. Lemeland, *C. A.* **17**, 2436, 3036). The united Et_2O - C_6H_6 exts. were centrifuged and the clear soln. was decanted into a Kjeldahl flask which contained the residue of Soln. B. The liquid was then evapd. and P was detd. in the residue as under total P. Nucleic P was detd. by the method of Javillier and Allaire (cf. *C. A.* **19**, 3100). Thus detns. were made on 70 samples of tissues from horse, pig, ox, calf and sheep; the results are shown in a 2-page table. The comments and conclusions fill 7 pages. Total P ranged in the dry material from 0.156% in pig thyroid to 2.03% in calf thymus. Lipoid P ranged from 0.101% in sheep thyroid to 1.552% in ox spinal cord. Nucleic P ranged from about 0.01% in pig spinal cord to 1.25% in calf thymus. The ratios of the percentages of these different combinations of P in the various tissues are discussed at much length. Also in *J. pharm. chim.* (8) **1**, 513-25 (1925). L. W. RIGGS

Uranic combinations of hexamethylenetetramine. EUGENE ISNARD. *Bull. sci. pharmacol.* **32**, 659-61 (1925).—An attempt was made to combine $(\text{CH}_2)_6\text{N}_4$ with $\text{UO}_2(\text{NO}_3)_2$ to form a substance having antisiphilitic properties. The result was not altogether successful. L. W. RIGGS

The reputed medicinal properties of precious stones. F. PONDER. *Pharm. J.* **115**, 686-7, 750-1 (1925).—A list is given of rare "stones" of animal, mineral and imaginary origin, with their reputed healing powers. Their failure indirectly contributed to the advance of medicine. S. WALDBOTT

Note on some British Pharm. galenicals. H. COUCH. *Pharm. J.* **115**, 687-9 (1925).—Concise modifications of the official processes are given for the *practical* prepn. in larger quantities of: (1) dil. acids, (2) effervescent prepn.s, (3) *extractum ergotae liquidum*, (4) *ext. nucis vomicae liquidum*, (5) *glycerinum acidi borici*, (6) *syrrupus ferri iodidi*, (7) *syrr. toluanus*. S. WALDBOTT

Cotarnine hydrochloride. D. B. DOTT. *Pharm. J.* **115**, 757(1925); *Chemist & Druggist* **104**, 7-8(1926).—The alkaloid, generally thought anhyd., has the compn. $(C_{12}H_{15}NO_4)_2 \cdot 3H_2O$, proved by the yield of anhyd. HCl-salt after drying below 100° . The HCl-salt has the compn. $(C_{12}H_{13}NO_3 HCl)_2 \cdot 5H_2O$. S. WALDBOTT

Benzylmorphine hydrochloride. D. B. DOTT. *Pharm. J.* **115**, 757-8(1925); *Chemist & Druggist* **104**, 7-8(1926).—This salt when crystd. from H_2O has the compn. $C_{24}H_{27}NO_3 HCl \cdot H_2O$; a slightly higher loss on drying below 100° may be due to adsorbed H_2O , or it may point to the compn. $(C_{24}H_{25}NO_3 HCl) \cdot 4.5H_2O$. Soly. of the salt in H_2O 1:160, in 90% EtOH 1:140 (wt./vol.). S. WALDBOTT

Estimation of cinchona preparations. D. B. DOTT. *Pharm. J.* **115**, 758(1925); *Chemist & Druggist* **104**, 8(1926).—Extg. the alkaloids with a mixt. of C_6H_6 and Et_2O (3:2) yields a residue of lighter color than that obtained by the official method, with AmOH; the neutralizing values are the same in both cases. S. WALDBOTT

Red quebracho bark. E. M. HOLMES. *Pharm. J.* **116**, 4(1926).—A recent com. lot of "quebracho blanco" bark differed from the true *Aspidosperma quebracho-blanco*, Schlecht. mainly by having a bright red inner bark; it probably belongs to *A. quebracho-colorado*, Schlecht. As the true bark is used in dyspnea, a physiol. study of the new bark is desirable for comparison. Com. "red quebracho bark," used for prepg. tanning exts., belongs to an entirely different natural order, Anacardiaceae. S. WALDBOTT

Quebracho bark. G. R. A. SHORT. *Pharm. J.* **116**, 103-4(1926).—A recent com. sample had all the characters of that described by Holmes (cf. preceding abstr.). Both, however, must be referred to *Quebrachia lorentzii*, Griseb. (Anacardiaceae), on account of the identity of structure, and the known variation in the color of the bark of this tree; pieces of pink color may be found both among the com. and some authentic specimens. The naming of the species *Aspidosperma quebracho-colorado* by Schlechtendal (1861) was based on error. S. WALDBOTT

Further note on tinctura cardamomi composita, Brit. Pharm. 1914. J. GREEN-HALGH. *Pharm. J.* **116**, 4-5(1926); cf. *C. A.* **17**, 3749.—A sample made by the B. P. method (A), contained about 25% of a flaky ppt. on 2 days' standing in hot weather, while a sample made by the suggested method (B), gave only 8%. After filtering and setting aside for 6 months, B remained brilliant and without pptn.; A was cloudy. Exposure to frost increased pptn. in A, but left B entirely clear. The B. P. formula for A should be discontinued. S. WALDBOTT

Dispensing note: Bismuth subnitrate. W. S. STANNARD. *Pharm. J.* **116**, 33-4; W. S. GLASS. *Ibid* **96**(1926); cf. *C. A.* **17**, 2171.—Of 9 exptl. mixts. made to find the best method of suspending $BiONO_3$ (A), the mixts. A + glycerol + H_2O , and A + sirup + H_2O (both 1:4:32) showed ready diffusion and slow pptn. of A; in the mixt. A + H_2O (1:32), A ppts. more readily; in the mixt. A + compd. infusion of gentian (1:32), A readily diffuses and ppts. very slowly. If a suspending agent is ordered, use A + compd. powd. tragacanth + H_2O (1:0.5:32); the tendency of the ppt. to clot is not serious within 3 or 4 days. The suspending properties of the mixt. A + mucilage of starch + $CHCl_3 \cdot H_2O$ (1:8:32) gradually disappear completely; A then ppts. as if in H_2O . S. WALDBOTT

Some new, modified and tested formulas of the Brit. Pharm. Codex. F. BROWNE AND DOROTHY G. RANDLE. *Pharm. J.* **116**, 57-61, 65; *Chemist & Druggist* **104**, 81-5 (1926).—An exptl. reply to criticism on 34 prepn.s of the B. P. Codex, 1923. No change is needed in 13 formulas; improved methods for the others are suggested. To obtain the pearly aspect of *Pasta hamamelidis*, use Poucher's formula for the soap (*C. A.* **19**, 1753) and a temp. not above 80° . Evap. *Parogenum spissum* to 17 instead of 18 ounces for better hardness. To avoid pptn. in *Syr. glycerophos. comp.*, add citric acid in given proportion; the temp. should not exceed 40° . *Spir. sapon. kalini*, made from soft soap, is equally as detergent as that from linseed oil soap of the B. P. C. *Ung. oleoresinae capsici comp.* is too strong and requires a 1:8 diln. with soft paraffin to render it tolerable on the skin. To prevent rubbery consistency of *Ung. resorcini et bismuth. comp.* reduce its starch content to half. In *Ung. iodi denigrescens*, "vaseline" may be replaced by using the formula of Mackie and Sharman (*C. A.* **18**, 3253). For rapid prepn., heat to 50° for 1 hr. in a closed vessel. To assay the ointment for I, strongly ignite 2 g. in excess of Na_2CO_3 , and titrate the aq. soln. with $AgNO_3$ and NH_4CNS . In examg. elixirs, the *soly. of sugar in glycerol* was found to be 7:100 at 20° . S. WALDBOTT

Influence of homogeneous neutral and of neutral zinc glass on the preservation of sterilized preparations (BARO) 19. Organo-mercury compounds (Brit. pat. 236,538) 10. Organo-arsenic compounds (Brit. pat. 235,864) 10. Filtering hydrocarbon lubricating oils [for medicinal use] (U. S. pat. 1,570,890) 22.

EVERS, NORMAN. The Chemistry of Drugs. New York: D. Van Nostrand Co. London: E. Benn, Ltd. 247 pp. \$9 00 (32s. 6d.) Reviewed in *Am. J. Pharm.* 98, 71(1926).

The Chemist and Druggist Diary, 1926. London: The Chemist and Druggist. 460 pp. Reviewed in *Pharm. J.* 116, 38(1926).

Formaldehyde. K KAISER. Brit. 236,086, Oct. 17, 1924. In oxidizing CH_4 to CH_2O , a catalyst is used which may be prepd. by impregnating pumice or similar inert carrier with a soln. of Cu, Fe, Mn or Cr sulfate and heating with a soln. of Na_2CO_3 or NaOH. A nitrate also may be used and converted into oxide for catalytic use. Ppdt. products also may be formed from colloidal oxides, for use as catalysts.

C,C-Disubstituted barbituric acids. J D. RIEDEL AKT.-Ges. Brit. 236,146, June 28, 1924. The process of Brit. 223,221 (C. A. 19, 1179) is modified by the introduction of the β -chloroallyl instead of the β -bromoallyl group. β -Monochloroallyl-isopropylbarbituric acid is made by heating a soln. of isopropylbarbituric acid in NaOH with 1,2-dichloro-2,3-propylene or by treating the Na salt of isopropylbarbituric acid with 1-bromo-2-chloro-2,3-propylene.

Organic arsenic compounds. CHEMISCHE FABRIK AUF AKTIEN FORM. F. SCHERING. Brit. 236,563, July 2, 1924. An alkali soln. of *p*-hydroxy-*m*-aminobenzenearsonic acid is treated with phosgene (preferably in the presence of NaOAc), at a temp. of 50° ; on acidification, the symmetrical urea of *p*-hydroxy-*m*-aminobenzenearsonic acid is obtained. By reacting upon *p*-hydroxy-*m*-aminobenzenearsonic acid with *m*-nitrobenzoyl chloride, *m*-(*m*-nitrobenzoylamino)-*p*-hydroxybenzenearsonic acid is obtained, which yields the corresponding amino compd. on reduction with ferrous salt; treatment with phosgene produces the symmetrical urea of *m*-(*m*-aminobenzoylamino)-*p*-hydroxybenzenearsonic acid. *p*-Hydroxy-*m*-aminobenzenearsonic acid is first treated with *m*-nitro-*p*-tolyl chloride and reduced and the product is further treated with *m*-nitrobenzoyl chloride. On reacting on the resulting compd. with phosgene there is formed the symmetrical urea of *m*-(*m*-aminobenzoyl-*m*-amino-*p*-tolylamino)-*p*-hydroxybenzenearsonic acid. These compds. are therapeutic.

Immunizing substances from blood serum. ELECTRO-OSMOSE AKT.-GES. (Graf Schwerin Ges.). Brit. 236,535, July 1, 1924. Blood serum or a pathol. effusion from a tuberculous or otherwise diseased or convalescent patient is subjected to the action of a continuous elec. current in a 3-cell electroosmotic app. to ppt. eglobulin and antigens and leave a clear soln. from which substances which carry pseudoglobulin may be salted out with MgSO_4 or $(\text{NH}_4)_2\text{SO}_4$, dissolved in H_2O , purified by further electroosmotic treatment, evapd. *in vacuo* and dissolved in salt soln. for therapeutic use. Ascitic fluid from a tuberculous patient may be treated by this process.

Extracting henna. COTY SOC. ANON. Brit. 236,557, July 2, 1924. Coloring matter is extd. from henna leaves by treating the crushed leaves with a warm or cold aq. soln. of an alk. earth salt (e. g., Ca and Mg salts from the Solvay ammonia-soda process). The aq. soln. is acidified with HCl, filtered and extd. with an immiscible solvent such as gasoline or C_2HCl_3 . The soln. in the volatile solvent thus obtained is further extd. with an aq. soln. of an alk. earth salt, the coloring matter is pptd. with acid, filtered off and dried. An app. is described.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

The gypsum-sulfuric acid process. W. J. MÜLLER. *Umschau* 30, 28-30(1926).—A description with flow sheet of the plant of the Farbwerke vormals Friedrich Bayer and Co. in Leverkusen, for the manuf. of H_2SO_4 and cement from gypsum. J. H. P.

Nitric acid production by the submerged Brunler flame. OSCAR BRUNLER. *Chem. Age* (London) 14, 29(1926).—The internal-combustion boiler with submerged flame (C. A. 19, 1211) has been applied to the evapn. and concn. of chem. liquors. Expts.

have been made to det. if it is possible to manuf. $\text{Ca}(\text{NO}_3)_2$ and if so whether the cost is less than that by the present processes. In preliminary expts. 19.05 kg. HNO_3 per hr. was obtained from 60 kg. oil and 290 cu. m. air. The HNO_3 yields increase with increasing boiler pressure; hence com. installations must be designed for high pressures. At a boiler pressure of 56 lbs. per sq. in. 4% of the wt. of the combustible mixt. supplied to the boiler is converted to HNO_3 . At 200 lbs. per sq. in., approx. 8830 kg. of gas and air will produce 441 kg. HNO_3 . In addition to this HNO_3 there is also produced utilizable power, estd. at 2090 h. p. per 1000 cu. m. gas. It is concluded that $\text{Ca}(\text{NO}_3)_2$ can be produced very economically as a by-product by burning a flame submerged in lime water.

J. H. PERRY

Determination of strength of liquid hydrocyanic acid by specific gravity. MARK WALKER AND C. J. MARVIN. *Ind. Eng. Chem.* 18, 139-42(1926).—A sp. gr.-temp. table has been worked out by means of which the HCN content of a $\text{HCN-H}_2\text{O}$ mixt. contg. over 80% HCN can be detd. with an accuracy of $\pm 0.1\%$, given the sp. gr. and temp. of the mixt.

F. C. Z.

Calcium cyanide—"powdered hydrocyanic acid." A new product of manufacture. F. J. METZGER. *Ind. Eng. Chem.* 18, 161-3(1926).—A new compd., $\text{Ca}(\text{CN})_2 \cdot 2\text{HCN}$ or $\text{CaH}_2(\text{CN})_4$, is made by treating CaC_2 with HCN, C_2H_2 being evolved. This Ca cyanide contains about 55% CN and is useful as a fumigant. It is safer to handle, more stable and possesses a wider margin of safety in application than liquid HCN.

F. C. Z.

Note on "influence of reaction rate on operating conditions in sulfuric acid manufacture." W. K. LEWIS AND E. D. RIES. *Ind. Eng. Chem.* 18, 213(1926).—The explanation of the use of the equations in a former article (*C. A.* 19, 2111) is amplified.

F. C. Z.

Investigation of processes for the catalytic oxidation of ammonia under conditions used in practice. V. I. MALIAREVSKII AND N. A. MALIAREVSKA. *Z. angew. Chem.* 38, 1113-8(1925).—The air was preheated to 150-330° before mixing with the NH_3 . The Pt wire gauze was 1000 mesh per sq. cm., of 0.09 mm. wire. This gauze, in 2 to 4 layers, was placed flat over the cross-section of the 300-mm. diam. converter. Under otherwise identical conditions, the contact temp. is proportional to the NH_3 concn. of the entering gas mixt. (These temps. were not true gauze temps.) In practice, variations from this proportionality are due to the higher temps. used and the correspondingly higher radiation losses. The essential factors which influence the oxidation of NH_3 are contact temp., gas velocity, thickness of the contact layer. The % yield of NO as a function of the contact temp. has been detd. for 2, 3 and 4 layers of Pt gauze under the following conditions: gas velocity, 20-50 m./min.; contact temps., 375-750°; NH_3 concn. of entering gas, 3.3 to 12.0%. With the 3-gauze catalyst the optimum NO yield (92%) was obtained with a gas velocity of 40 m./min., giving a time of contact with the catalyst of 0.00034 sec.; NH_3 concn., 8.7%; and a temp. of 620°. With the 2-gauze catalyst, the optimum NO yield was reached at a considerably lower gas velocity, i. e., 20 m./min. With a 4-gauze catalyst, the max. NO yield (90.8%) was obtained with a gas velocity of 50 m./min.; 9.2% NH_3 gas mixt.; and at 666°.

Hydrogen for hydrogenation of oils. A. E. KNOWLES. *Chem. Age* (London) 14, 26-8(1926).—K. briefly traces the methods of prep. H_2 for oil hydrogenation, and concludes that pure electrolytic H_2 should always be used. Its cost is detd. by: (1) the price of electricity, and (2) the value of the by-product O_2 . An installation should be planned after the lowest combination of cost of electricity and interest and depreciation on capital cost of the plant has been detd.

W. H. BOYNTON

Carbon black produced from natural gas in 1924. G. B. RICHARDSON. U. S. Geol. Survey, *Mineral Resources of U. S., 1924*, Part II, 121-3 (preprint No. 10, published Nov. 2, 1925). E. H.

Feldspar in 1924. JEFFERSON MIDDLETON. U. S. Geol. Survey, *Mineral Resources of U. S., 1924*, Part II, 19-25 (preprint No. 5, published Oct. 13, 1925). E. H.

Slate in 1924. G. F. LOUGHLIN AND A. T. COONS. U. S. Geol. Survey, *Mineral Resources of U. S., 1924*, Part II, 151-60 (preprint No. 13, published Dec. 16, 1925). E. H.

Graphite in 1924. JEFFERSON MIDDLETON. U. S. Geol. Survey, *Mineral Resources of U. S., 1924*, Part II, 13-7 (preprint No. 4, published Oct. 8, 1925). E. H.

Casein and its industrial applications. F. C. C. LYNCH. *Can. Chem. Met.* **9**, 264 (1925); **10**, 13-6 (1926); cf. *C. A.* **19**, 3568.—A short survey is given of the use of casein in the following fields and industries: medicinal foods, medicines, textiles, soap, asbestos products, insecticides and fungicides, photography. Reference is made to sundry uses of casein. A few figures on the production and use of casein in the U. S. A. are tabulated. The casein industry in Argentine, France, Germany, England, Denmark and other European countries, New Zealand, Australia and Japan are very briefly dealt with. E. G. R. ARDAGH

Carbonizing bones. GG. ILLERT. *Chem.-Ztg.* **49**, 881 (1925).—Bones freed from fat by extn with suitable solvents are ground, carbonized in air-tight vertical retorts at about 700°, cooled in suitable coolers, and then discharged into cars or upon conveyors. In the Otto Ruf (Munich) system described, evolved gases are passed through condensers for collecting NH_3 , and small quantities of bone oil are recovered also. The bone black is recovered cold, an advantage over the practice of discharging it into the air while red-hot. W. C. EBAUGH

The adsorption of gases by wood charcoal (HENGLEIN, GRZENKOWSKI) **2**. The production of H by microorganisms (THAYSEN) **16**.

Hydrocyanic acid. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAP. Brit. 235,181, June 3, 1924. HCN is made by treating, in an elec. arc furnace of the "blown arc" type (preferably of the Birkeland-Eyde kind), a mixt. of N, H and a hydrocarbon under such conditions that the gases, after leaving the arc, have a temp. not above 600° and do not come in contact with walls of a temp. above 400°. The metal walls of the app. may be cooled and the cooling utilized for steam generation.

Hydrochloric acid free from arsenic. E. SCHMIDT. U. S. 1,571,648, Feb. 2. Activated charcoal is used for removing As and Fe from HCl solns.

Ammonia oxidation. I. W. CEDERBERG. Brit. 236,145, June 24, 1924. NH_3 -O mixts. for producing N oxides (or other gaseous mixts. for catalytic reactions) are forced through a small clearance space (about 1 mm.) between a catalyst and the wall of the reaction vessel.

Ammonium chloride. T. B. SMITH and SIMON-CARVES, LTD. Brit. 234,933, March 14, 1924. White "com'l." pure NH_4Cl crystals are obtained from crude NH_4Cl liquor by repeatedly circulating it over steam pipes until it is sufficiently concd. and then passing it to cooling and crystg. tanks.

Ammonium chloride and sodium sulfate. CONTINENTALE AKT.-GES. FÜR CHEMIE. Brit. 235,552, June 11, 1924. A solid mixt. of $(\text{NH}_4)_2\text{SO}_4$ and NaCl or KCl is heated in a stream of oxidizing gas, such as O, Cl or Cl peroxide, or with a peroxide, nitrate, chlorate, persulfate or hypochlorite. Pure white sublimed NH_4Cl and calcined Na_2SO_4 are obtained.

Ammonium sulfate. CHEMICAL ENGINEERING & WILTON'S PATENT FURNACE CO., LTD., T. O. WILTON and N. WILTON. Brit. 235,613, Feb. 20, 1924. $(\text{NH}_4)_2\text{SO}_4$ is fed onto a conveyor which carries it while it is being dried and neutralized by NH_3 or otherwise. The material passes successively through chambers in which it is neutralized, freed from excess moisture and delivered to a final drier. Many details of app. are described.

Sodium chloride. SALZBERGWERK NEUSTASSFURT and F. GROTOGINO. Brit. 235,020, July 3, 1924. NaCl is recovered by recrystg. rock salt from soln. by addn. of AlCl_3 , ZnCl_2 or KCl, alone or mixed, or mixts. of these salts with CaCl_2 or MgCl_2 .

Fluorides, etc. M. BUCINER. Brit. 235,588, June 14, 1924. A fluoride, e. g., NaF, is treated with CaCO_3 or other carbonate or hydroxide of a metal forming an insol. fluoride. Reaction is effected with heat and pressure and in the presence of a small

quantity of H_2O . The presence of CO_2 (which may be produced from added NaHCO_3) is advantageous in effecting the reaction between NaF and CaCO_3 .

Reducing phosphates, etc. H. MEHNER. Brit. 235,924, Jan. 1, 1924. Phosphates, silicates and other compds. reduced by C at high temps. are decomposed by heating them with C in the absence of air, with or without addn. of reagents such as SiO_2 or Fe, and the combustible volatile reaction products are burned in the reaction zone to supply sufficient heat to maintain the required temp. during the reaction and while a new charge is being introduced. Low-grade phosphate, leucite or feldspar, greensand, clay and other similar materials may be thus decomposed.

Borax from saline liquors. A. W. GAUGER and H. H. STORCH. U. S. 1,571,002, Jan. 26. Other salts which are present with borax in soln. are crystd. and the mother liquor is chilled and agitated after sepn., in contact with a finely divided material such as added borax to cause rapid crystn. of borax.

Removing silica from ore leaches. M. HOSENFELD. U. S. 1,571,054, Jan. 26. A powd. insol. substance such as barite 0.5% at a temp. of 70° is mixed with the jelly setting from an ore leach, H_2O is removed, and the resulting product is pulverized, to obtain a material adapted for fertilizer manuf.

Apparatus for drying and calcining gypsum. C. DRESSLER. U. S. 1,571,189, Feb. 2.

Lead salts. CONSORTIUM FÜR NASSMETALLURGIE. Brit. 236,440, Nov. 14, 1924. Pb ores, slags, sludges and similar materials are rendered acid with HCl , if necessary, and treated with a strong soln. of an alkali or alk. earth metal chloride to obtain a soln. of the Pb. The soln. is purified from Fe by pptn. after oxidation with air, Cl, Br, chlorates or nitrates; and Ag and like metals may be removed by use of granulated or spongy Pb. The purified soln. is then treated with a dichromate, arsenate, antimonate, molybdate, tungstate or uranate to obtain the corresponding Pb salt.

Lead oxides. G. SHIMADZU. Brit. 236,368, June 26, 1924. Pb suboxide mixed with some metallic Pb is produced by treating pieces of Pb in a rotating drum with air or other oxidizing gas. The product is very light and is readily converted into PbO by heating it locally to initiate the reaction. H_2O reacts with it to produce PbO and Pb hydroxide and the PbO may be converted into Pb_3O_4 by heating at temps. not exceeding 500° .

Zinc oxide. NEW JERSEY ZINC CO. Brit. 235,844, June 17, 1924. In ZnO manuf. by the retort volatilizing process, SO_2 is associated with the fume produced by oxidation of the Zn vapors, to form white compds. with impurities such as Pb and Cd in the fume. H_2SO_4 mist also may be used. An app. is described.

Iron oxide, etc. W. S. MILLAR. Brit. 236,256, March 7, 1924. Ores such as Fe pyrites or pyrrhotite are desulfurized by treatment with SO_2 at a gradually increasing temp. which, however, does not exceed 950° , thus forming Fe_3O_4 and free S. The porous Fe_3O_4 thus formed may be further subjected to electromagnetic concn. and the S is recovered in condensing chambers. Steam facilitates the desulfurization.

Hafnium and zirconium compounds. NAAMLOOZE VENNOOTSCHAP 'PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 235,217, June 6, 1924. A mixt. of Hf and Zr salts contg. 2 or more of the phosphates, phosphites, arsenates, arsenites, antimonates or antimonites of these metals is dissolved in a medium contg. free oxalic acid, concd. H_2SO_4 or H_3PO_4 , and the Hf may be sepd. from the Zr by fractional pptn. which may be induced by dilution, heating, addn. of alc. or of HCl or an alkali. Alternatively, the original salt mixt., in suspension, may be treated to effect fractional soln., e. g., by treatment with H_3PO_4 of 1.75 sp. gr., the filtrate after each addn. of H_3PO_4 being pptd. with soda.

Krypton and xenon. SOC. L'AIR LIQUIDE, SOC. ANON. POUR L'ETUDE ET L'EXPLOITATION DES PROCEDES G. CLAUDE. Brit. 236,217, June 25, 1924. Kr and Xe are sepd. in an air liquefaction app. in which the richest liquid O is treated in a single receptacle arranged in the vaporizer and constructed so that progressive evapn. of the liquid takes place in its passage and a final small fraction is obtained for the subsequent extn. of the Kr and Xe.

Carbon disulfide. CHEMISCHE FABRIK GRIESHEIM ELEKTRON. Brit. 236,577, July 3, 1924. Carbonaceous material is heated to a glowing temp. (preferably in a sep. elec. furnace placed above the CS_2 -forming furnace) to degasify it before it is fed, with exclusion of air, to the CS_2 furnace. The CS_2 vapors produced do not pass through the preliminary degasifying furnace.

Recovery of filtration material. H. S. THATCHER. U. S. 1,571,074, Jan. 26. Material such as diatomaceous earth which has been used in the filtration of sugar solns. is dried in the form of filter-cake, finely divided and calcined at a temp. sufficiently high to remove part of the inorg. impurities. A temp. of about 1000° is suitable for calcination of diatomaceous earth.

Recovery of diatomaceous earth used for filtrations. P. A. BÖCK. U. S. 1,571,042, Jan. 26. After its use in purifying sugar solns. or other liquids, diatomaceous earth, with its associated impurities, is dried and heated to increase its filtration efficiency without removal of any substantial quantity of chem. combined H_2O .

Testing adsorbents for purifying liquids. F. G. P. REMFRY and A. E. DUNSTAN. Brit. 236,263, March 29, 1924. A mineral adsorbent such as bauxite is tested with respect to the amt. of heat given off when a sample of the material, immediately after roasting or ignition and without exposure to the atm., is moistened with oil or other liquid to be purified, and this test is taken as indicating the efficiency of the material for the purification of the oil or other liquid used in the test. The test may also serve to indicate the most suitable temps. for the roasting.

Stencil sheets. GREIFWERKE VORM. DEUTSCHE BÜROBEDARFS-GES. BRUER & CO. Brit. 235,516, June 10, 1924. A coating compn. for Japanese paper, etc., comprises a casein soln. emulsified with oils and fats, e. g., 1 kg. each of olive oil and a 10% alk. soln. of casein, 0.8 kg. of fixed white or $BaSO_4$ and sufficient H_2O to make a total of 3.5 kg.

Photomechanical printing surfaces. SACHSISCHES SERUMWERK AKT.-GES. AND A. GALETZKA. Brit. 236,532, July 1, 1924. An intermediate non-sensitive layer such as gelatin is interposed between a sensitive layer such as dichromated gelatin and the glass, stone, metal or other support, and is preferably coated with a thin coating of gelatin, waterglass and chrome alum. The H_2O during development penetrates through the unexposed parts and swells the intermediate layer, raising the exposed parts evenly.

Colloids for photomechanical printing plates. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 236,508, July 1, 1924. A gelatin layer having a m. p. of about 50° and dried at about 45° , when treated with washing H_2O at 30° , gives a pronounced grain, and, with H_2O at 25° , a fine grain.

Rubber printers' blankets. L. PEPE and D. DENAGY. Brit. 236,506, April 4, 1924. To protect fine-grained printing plates from the deleterious action of the S in rubber offset blankets they are coated with a compn. formed by dissolving casein in an alk. soln., pptg. with oxyglutaric acid, washing the ppt. and dissolving it with glutamic acid and dil. NH_3 soln. and mixing it with a soln. of liquefied gluten or serecin and with formaldehyde and propenyl alc.

Packing material. M. P. EBBESEN. U. S. 1,570,953, Jan. 26. A plastic, non-resilient packing adapted for use in pipe joints comprises soap, waterglass, starch, alkali carbonate, sugar, graphite and chalk. Cf. C. A. 19, 1477.

Friction lining material. N. KÜCHEN. Brit. 235,473, Dec. 8, 1924. A friction lining for brake shoes or the like comprises an alloy of Cu 58-64, Zn 32-38, Mn 0.5-2.5, Fe 0.5-2 and Al 0.01-2%.

Mixture for cleaning glass, etc. M. M. H. CUDWORTH. Brit. 236,436, Nov. 19, 1924. $KMnO_4$, guaiacum resin and borax $\frac{1}{4}$ oz. each, NaCl, alum, soda and H_3BO_3 $\frac{1}{2}$ oz. each, French chalk 1 oz., starch 2 oz., H_2O 5, vinegar $3\frac{1}{2}$, glycerol 1, turpentine 1 and "methylated spirit" $1\frac{1}{2}$ tablespoonfuls are used together.

Polish for brass, silver, etc. J. P. WILLIS. Brit. 235,986, April 8, 1924. Whiting $1\frac{1}{4}$, powd. "bathbrick" 1, venetian red $\frac{1}{4}$ and paraffin oil $3\frac{1}{2}$ oz.

Cooling internal-combustion engines. H. C. HAAK. U. S. 1,565,323, Dec. 15. A mixt. of CCl_4 5-15% with kerosene and lubricating oil or other mineral oil of high b. p. is used in the cooling system.

Wear-resisting surfaces of strawboard, etc. E. GANZ. Brit. 235,757, Sept. 19, 1924. Benches of strawboard for cutting up meat, leather, etc., are treated with rubber dissolved in linseed oil or with a chrome-treated glue soln. to render their surfaces resistant to wear.

Treating wood for use in boots and shoes. R. C. HAUSSLER. Brit. 236,429, Jan. 29, 1925. 3-Ply sheets are formed from Finnish birch or other wood low in acid. Before being glued together the sheets are treated with hot glycerol contg. $PhOH$ to soften the wood and render it antiseptic. The 3-ply product, after cutting to shape, may be exposed to formaldehyde vapor.

Inflating small balloons by chemically reactive substances. G. SCHÜTZLER. Brit. 236,505, March 21, 1925. Substances such as $NaHCO_3$ and tartaric acid are sepd. by a partition of paraffin or other readily frangible material, within a gas-tight envelope, such as that of a toy balloon so that the latter is inflated by the gas evolved when the partition is broken.

Apparatus for drying casein curd. E. FOSTER. U. S. 1,571,518, Feb. 2.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND METALS

G. E. BARTON, C. H. KERR

The physical properties of glass in relation to its composition. I. The electrical conductivity of glasses. G. GEHLHOFF AND M. THOMAS. *Z. tech. Physik* 6, 544-54 (1925).—In the majority of glasses there is some relation between the cond., the viscosity and the tendency to corrosion by chemicals. The degree of dissoen. decreases with increasing temp. Data and curves show the effect, on the cond. and the viscosity of a series of glasses, of the presence and amount of CaO, BaO, B₂O₃, Fe₂O₃, PbO, MgO, ZnO, SiO₂, Al₂O₃, K₂O and Na₂O. J. H. P.

Some factors involved in the preheating of glass pots with special reference to moisture control. W. W. OAKLEY. *J. Am. Ceram. Soc.* 9, 23-8 (1926).—"Heating in a humid atm. tends to equalize the rate of removal of moisture from the inside and the outside surface of the pot, at temps. above 212°, decreasing mech. strains set up" in the drying process. C. H. KERR

Antique glasses: their composition and coloring. BERNHARD NEUMANN. Analyses by GERTRUD KOTYGA. *Z. angew. Chem.* 38, 776-80, 857-64 (1925).—The necessity for lime in glass was not recognized until the 17th or 18th century apparently, it having previously been present through impure materials. In addition to 4 analyses of Old Egyptian glass and 29 of Roman glass found in the literature the authors have obtained 38 glasses which date from 1400 B. C. to 600 A. D., and publish the analyses of the same with comments. The color scale of the ancients comprised blue (from bright aquamarine to deep dark indigo), green (to a black green), rose, violet (to black), yellow (honey color, orange color to brown), red (sealing-wax color), white (transparent and opaque). These colors are had either with or without clouding. The coloring media were Cu, Pb, Sn, Mn and Fe oxides. Opaqueness is due either to insufficient melting or an excess of oxide. G. E. BARTON

The influence of homogeneous neutral and of neutral zinc glass on the preservation of sterilized preparations. A reagent for the identification of suitable glass. E. BARO. *Boll. chim. farm.* 64, 673-7 (1925).—Inhomogeneous glasses contg. ZnO are attacked by water at 134°. Phenolphthalein is not suitable for the detection of decompn. in these glasses. A reliable reagent was found in a freshly prepd. 0.1% alc. hematoxylin soln. which indicates 0.0005 N NaOH by a purplish rose color appearing within 2 hrs. The color varies with the nature and concn. of the bases from purple to azure for BaO, CaO, ZnO, Al₂O₃ and their mixts., and persists 48 hrs. Glass for ampules should give a negative hematoxylin test within 24 hrs. after 1 hr.'s heating with distd. water at 2 atm. MARY JACOBSEN

Clay in 1924. JEFFERSON MIDDLETON. U. S. Geol. Survey, *Mineral Resources of U. S. 1924*, Part II, 113-20 (preprint No. 9, published Oct. 31, 1925). E. H.

Mineralogy of clay. I. The mineral constituents of clay. II. Rational analysis of clay. J. S. McDOWELL. *J. Am. Ceram. Soc.* 9, 55-65 (1926).—A review of literature and short bibliographies. The methods of detg. rational analysis are shown to be inaccurate. C. H. KERR

A deformation study of various aluminosilicates and borosilicates. KAI-CHING LU. *J. Am. Ceram. Soc.* 9, 29-54 (1926).—Five ternary "deformation eutectics" were found: PbO : 0.254 Al₂O₃ : 1.91 SiO₂; ZnO : 0.225 Al₂O₃ : 0.906 SiO₂; PbO : 0.238 B₂O₃ : 0.78 SiO₂; Na₂O : 1.29 B₂O₃ : 1.73 SiO₂; K₂O : 2.11 B₂O₃ : 2.585 SiO₂. The approx. deformation temps. were 650°, 1360°, 415°, 570° and 655°, resp. All eutectics developed are within the 2½ mol. % limit. Combinations of eutectics were also made but no further lowering of temp. was noted. Complete data and diagrams are given. C. H. KERR

United States Government master specifications for plastic fire-clay refractories. ANON. Bur. Standards, *Circ. No. 297*, 5 pp. (1925). E. H.

An eighteen months' high-temperature test on refractory test specimens. F. H. RIDDLE AND A. B. PECK. *J. Am. Ceram. Soc.* 9, 1-22 (1926).—The effects are noted of an 18 months' run in a continuous kiln at cones 17 to 18. SiC, under oxidizing conditions, oxidizes to cristobalite, with great expansion, at temps. as low as 600°. At high temps. the expansion is not so great but volatilization is great. Spark plug bodies were almost unchanged up to 1200°. Above 1200° the size of the mullite crystals increased slightly. Pyrometer tubes showed much greater increase in size of crystals and a tendency to blister and craze. A mortar of SiC used with SiC refractories showed swelling and good filling of the joints. SiO₂ glass, found in the water-smoking zone, was probably derived

from volatilization of SiC and SiO₂ brick in the hot zone with pptn. of SiO₂ glass when the SiO₂ gases came into contact with steam. Crystals of a mixt. of Fe₃O₄ and Fe₂O₃ were found in the cooling zone, indicating a possibility that the dissociation temp. of Fe₂O₃ is lower than previously supposed. C. H. KERR

Refractories for the open-hearth. I. S. LONGENECKER. *Iron Age* 116, 1735-8 (1925).—Conclusions drawn from a study of failure of magnesite brick are that: too soft burning causes failure; the kiln burning temp. is all-important; the modulus of rupture is the best means for the consumer to gage the "burn"; and the brick is greatly weakened by the use of a lumpy nonuniformly ground mix. Tentative specifications are given. The chem. analysis specified is: MgO, over 82%; CaO, under 5%; SiO₂, under 7%; Fe₂O₃, under 8%; Al₂O₃, under 3% and Fe₂O₃ + Al₂O₃, under 9%. W. H. BOYNTON

Theory of coal measure fire clays (LOVEJOY) 8. Water filtration and softening as applied to clay-products plants (MARSH, McLELLAND) 14.

Glass. A. H. COMPTON. U. S. 1,570,876, Jan. 26. Glass resistant to chem. action of vapors of metals of the Na group comprises B₂O₃, basic oxides including at least one of the alkali metal oxides and at least one of the oxides of Ca, Ba, Sr or Mg, and Al₂O₃, *e. g.*, Na₂O 13, Al₂O₃ 15, CaO 12 and B₂O₃ 60%.

Kiln and heating system for annealing glassware. V. MULHOLLAND. U. S. 1,571,137, Jan. 26.

Annealing and cooling sheet glass by gas currents. F. L. BISHOP. U. S. 1,570,822, Jan. 26.

Temperature and humidity regulation in drying bricks, pottery or other refractory ware. W. E. WILSON and H. G. LYKKEN. U. S. 1,570,659, Jan. 26.

Kiln for pottery, etc. H. T. PADELT. Brit. 235,459, Nov. 13, 1924.

Tunnel kiln with preliminary heating, burning and cooling zones. N. LENGERSDORFF. Brit. 236,229, Feb. 26, 1923.

Kiln adapted for burning ceramic ware. N. LENGERSDORFF. U. S. 1,571,058 Jan. 26.

Refractory articles from clay. B. BELL. Brit. 236,063, Aug. 13, 1924. Cores for Hg cut-outs or other refractory hard articles for elec. or other purposes are made from purified clay contg. 50% or more of SiO₂. Details of firing temps., etc., are given.

Steel and slag for making refractory articles. F. A. DESILVA. Brit. 236,255, March 6, 1924. In the direct treatment of Fe sand or titaniferous Fe ore in an elec. furnace, there is produced a high-grade steel of low C content and a highly refractory slag which may be run into molds and cast into bricks, tiles, crucibles, furnace linings, etc. Numerous details of procedure are given.

Refractory furnace linings. E. HOLLEY. Brit. 235,505, Jan. 10, 1925. A wash for repairing furnace linings is formed of fireclay or similar material 25, H₂O 70% and 5% of "C grade" Na silicate which may have the compn. 5(Na₂O).11(SiO₂).46(H₂O).

Hollow ware from refractory substances. C. C. SCHNUR. U. S. 1,571,607, Feb. 2. In working refractory material such as SiO₂ a tubular billet of the material is formed by fusion with an elec. arc, the arc is then extinguished and the material is drawn into elongated form, *e. g.*, tubing.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Ready means of estimating quantities of cement materials. F. E. GLASS. *Eng. News-Record* 95, 965-6(1925).—The method of estg. is based on the assumption that cements, coarse and fine aggregate, all weigh approx. 100 lbs. per cu. ft. and that the av. wt. of plain concrete is 145 lbs. per cu ft. The method provides means of detg. the approx. wt. of materials required for the odd proportions encountered when the mix is controlled by screening tests and fineness modulus. Accuracy is equiv. to that of methods used heretofore. R. E. THOMPSON

Influence of sugar on the properties of cement. ANON. *Sucr. belge* 44, 612 (1925).—Reference is made to expts. on the effect of sugar in the water used in cement mixing on the setting and hardening of cement. It was found that the resistance to compression of cement blocks that were made with water contg. 0.1% of sugar is superior to that of blocks made from cement mixed with pure water. It is also shown

that wet concrete coming in contact with sugar is stronger than concrete that is merely wet with water.

Concrete improved by the use of diatomaceous earth. C. N. CONNER. *Eng. News-Record* 95, 995-6(1925).—Expts. carried out by the N. Carolina State Highway Commission indicate that addn. of diatomaceous earth increases the strength and promotes workability of concrete. The diatomaceous earth used was a specially prepd. material known commercially as celite; it was of the plankton marine type.

T. MARKOVITS

Admixtures in concrete. T. P. WATSON. *Eng. News-Record* 95, 1084(1925).—The statements Conner (cf. preceding abstract) are at variance with the experience of W., which has been that compressive strength of concrete is dependent on the cement-water ratio of the mixt., irrespective of proportions, with or without powdered admixtures. Use of the latter necessitated in all cases additional water to obtain the same workability, which reduced the compressive strength accordingly.

R. E. THOMPSON

More on concrete admixtures. G. M. WILLIAMS. *Eng. News-Record* 96, 129(1926).—Discussion of Conner's work (cf. preceding abstracts), with special reference to "oversanded" mixts., which are shown to be superior under certain conditions, the fineness of the sand, expressed as surface area, being the controlling factor. Sands having a surface area of less than 700 sq. in. per 100 g. permitted the use of a sand-gravel ratio of 1.0, while sand approaching 1100 sq. in. gave the best results with a ratio of 0.5. In the case of a Saskatchewan sand of surface area of 350-500 sq. in., a ratio of 1.0-1.5 gave the best quality concrete, which was stronger and more easily placed than mixts. conforming to 2:4 and 3:6 ratios. These "oversanded" concretes require a greater quantity of mixing water and are less dense but more water-tight or impermeable.

R. E. THOMPSON

Concrete admixtures. G. W. HUTCHINSON. *Eng. News-Record* 96, 129-30(1926).—Criticism of Watson's discussion (preceding abstract).

R. E. THOMPSON

Predetermining concrete strength on Park Bridges. W. F. WELSCH. *Eng. News-Record* 95, 630-1(1925).—Details are given of the successful application of a scientific method of designing concrete mixts. based on the researches of Abrams. It was found desirable, as a factor of safety, to increase slightly the quantity of fine aggregate computed as a slight deficiency results in porous concrete.

R. E. THOMPSON

Water-cement theory as a fact in field control of concrete. J. G. AHLERS. *Eng. News-Record* 95, 674-5(1925).—Discussion of the cement-water ratio method of concrete control, which is shown to be very satisfactory and practical. Grading of aggregate need only be controlled by the workability of the mix.

R. E. THOMPSON

Concrete pit structure subjected to diverse stresses. A. E. WYNN. *Eng. News-Record* 95, 762-3(1925).—Description of the construction of a water-proof reinforced-concrete structure required to withstand possible external hydraulic pressure. For water-proofing, reliance was placed mainly on the quality of the concrete, with addn. of an integral water-proofing compd. Very dense homogeneous concrete was obtained by the use of crushed limestone aggregate with crushed stone dust substituted for sand. The construction joints were reinforced with 20-oz. Cu baffle strips bent over on each side of the joint. The structure has been in use 5 months and has proved entirely satisfactory.

R. E. THOMPSON

Was Gem Lake Dam disintegration due to underburned cement? LARS JORGENSEN. *Eng. News-Record* 95, 606(1925).—A very heavy white deposit of practically pure CaCO_3 , noticed on the downstream face of Gem Lake Dam prior to failure, which had increased to a thickness of $1\frac{1}{8}$ in. in places and appeared to continue to increase, cannot be explained by a study of the water, rock or sand and must have been due to decomposition of the cement. Small white deposits often seen on dams originating from the leaching out of the free lime of the cement or of laitance accumulated in construction joints is harmless and should stop when these materials are all leached out. In this case the action continued, the cement itself being affected. Although the cement employed conformed to the usual tests it may have been somewhat underburned and on the point of instability when exposed to severe low temps.

R. E. THOMPSON

Silicate protective coatings for artificial stone. F. HUTH. *Farbe und Lack* 1925, 606.—A review of the use of Na silicate for hardening concrete floors, artificial building stone, etc.

F. A. WERTZ

The gypsum-sulfuric acid process (MÜLLER) 18. Drying blast-furnace slag [for the manufacture of cement] (ZILLGEN) (SCHNEIDER) 9. Ore reduction and cement manufacture (Brit. pat. 235,606) 9.

LAKEMAN, ALBERT: **Elementary Guide to Reinforced Concrete.** London: Concrete Publications, Ltd. Paper, 6 X 9 in., 69 pp., 79 line cuts. 2s. Reviewed in *Eng. News-Record* 95, 645(1925).

Aluminous cements. C. PONTOPPIDAN and H. P. BONDE. Brit. 235,138, June 5, 1924. Cements with a high Al_2O_3 content are burned in a rotary kiln while protected from direct radiation from the flame, to prevent fusion. The flame may be surrounded by an annular jet of air or may be dild. by an excess of air, or a relatively cool and widely diffused flame such as that of producer gas may be used, or the kiln shell may be cooled at the point where the flame is formed.

Porous concrete. J. A. ERIKSSON. Brit. 235,006, June 17, 1924. In making porous concrete or "gas concrete" from cement or cement and lime, with or without slate-ashes, blast furnace slag, slate-lime, pumice or the like and metal powder which causes the generation of gas on mixing with H_2O , the solid constituents are mixed and finely divided and then stirred with H_2O and transferred to molds.

Fibrous materials in concrete. NOVOCRETES, LTD., G. O. CASE and J. R. GARROW. Brit. 236,450, March 27, 1924. See U. S. 1,537,406 (*C. A.* 19, 2118).

Concrete and mortar. R. SCHOENHOFFER. Brit. 235,257, Feb. 12, 1924. Materials such as ashes, flue dust, or slag are crushed and ground while moist and may be heated and mixed with small quantities of alk. hydroxides and salts, Mg, Ca or Al salts, alk. silicates, Fe oxides and salts and various inert fillers.

Impregnating fibrous material with metallic salts. J. R. GARROW. U. S. 1,571,048, Jan. 26. A soln. of a normal metallic salt such as FeCl_3 is treated with NaOH or other alk. substance so that a slight excess will produce a permanent ppt., sawdust or other fibrous material is impregnated with the soln. thus prepd. and the material is then treated with a further quantity of alk. substance to form a ppt. in and on the fiber and render it suitable for use with cement.

Roads. C. B. FILBERT. Brit. 234,891, March 3, 1924. A macadam road is repaired by removing dust and applying a penetrating primary coating of light oil contg. 45-65% asphalt, on which is placed a secondary coating of heavy oil contg. 65% or more asphalt and a surface dressing of fine mineral aggregate.

Forming roads with bituminous mixtures. J. RADCLIFFE. Brit. 236,050, Jan. 2, 1924. Pitch for use in road making is preferably ground with sand in an impact mill and can be transported without caking. Other details are specified.

Surface composition for tennis courts, paths, etc. W. EVERITT (BRITISH CHEMICAL PRODUCTS). Brit. 236,345, May 24, 1924. Sand, rosin, solvent naphtha, petroleum oil, terebene and Fe oxide or other pigments are used.

Preserving wood. C. DE ZUTTERE. Brit. 236,328, May 1, 1924. Creosote is mixed with phenolated bitumen from lignite tar, with or without C_{10}H_8 or petroleum, to reduce the proportion of phenol.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Experiments on a new low-temperature tar-recovery gas producer and plant. F. KAISER. *Braunkohle* 24, 673-8, 699-704, 718-24(1925).—A detailed description of a by-product producer for brown-coal briquets, of its accessory app. and of tests performed. The producer consists of a vertical carbonizing shaft superposed on and discharging immediately into the gasifying chamber. The following data are illustrative of the 3 tests performed. *Throughput* 1000 kg./hr. of brown-coal briquets having a heating value of 4795 kg. cal./kg., contg. 6.47% ash, 17.34% H_2O , 76.19% combustible. *Total mixed gas*, 1.915 cu. m./kg., heating value 1755 kg. cal./cu. m., contg. 7.4% CO_2 , 0.3% illuminants, 0.4% O_2 , 27.0% CO, 3.3% CH_4 , 18.4% H_2 . *Tar yield*, 7.92% (yield in lab. expts. 9.55%). Heat balances, etc., are given and the economics of the process discussed in detail.

WM. B. PLUMMER

Constitution of coal. R. THIESSEN. *Trans. Am. Inst. Min. Met. Eng.*, Feb., 1925, (advance copy), 50 pp.—The chemistry of plant substances, their decay and subsequent transformation into peat is reviewed. Cellulose, although constituting the bulk of the plant body, does not contribute materially to the peat bog. The relative progressive change of the C and O content begun during the biochem. stages continues during the successive changes into brown coal, lignite, bituminous coal, and anthracite. All of the components of peat, definitely recognizable, may be traced clearly through

the whole series of coals. The woody components—anthraxylon—of peat, converted into coal, give rise to "bright" coal; the attritus of peat partakes of a dull appearance and gives rise to "dull" coal. B. C. A.

Sulfur in coal and coke. J. W. MEUSER. *Het Gas* 45, 97-107(1925).—A phase-rule study of the C-S complex in equil. with C at elevated temp. proves that S exists (1) as free, adsorbed S, (2) in solid soln. in the coal, or attached to the surface in such a way that it is impossible to distinguish it from a solid soln. Coke, prepd. in the lab. by heating coal contains S in 3 forms: (1) free, adsorbed S, (2) in solid soln., (3) as FeS with some MgS and CaS. If the coke is heated for a long time, the adsorbed S will slowly pass into solid soln. A coke which has been prepd. by the ordinary com. process contains S in a solid soln. and as FeS, before cooling. After cooling, even with limited access of air, FeS is oxidized, according to the reaction: $4 \text{FeS} + 3 \text{O}_2 = 2 \text{Fe}_2\text{O}_3 + 4 \text{S}$. If the coke is quenched, this oxidation is incomplete because of the sudden drop of temp., but, even at 500°, the oxidation is complete. If H_2 , or a gas contg. H_2 , is run through the chamber contg. red-hot coke, the S is completely transformed into H_2S . R. BEUTNER

Characteristics of American lignites. M. DOLCH. *Braunkohle* 24, 918-24(1926).—A review of various data from the Canadian Lignite Board publications. W. B. P.

Study of the ash of lignites. UGO MONDELLO. *Rass. min. met. chim.* 63, 126-9 (1925).—If in the distn. of a solid combustible like lignite, no part of the mineral matter passes off as a result of decompn. or entrainment, then the % ash in the coke agrees with the theoretical value calcd. from the % coke and the % ash in the original combustible. Tests, however, on numerous different lignites, whereby the latter were distd. with superheated steam (cf. C. A. 19, 2268), showed that in most cases the actual % in the coke was less than the theoretical value, but in a small proportion of cases was higher. Furthermore, where it was lower or higher than the theoretical, these differences bore no relation to the % volatile or to the % coke. In most cases where the % ash in the coke was lower than the theoretical, this deficiency was the greater the lower the % ash in the original combustible. This loss or gain of mineral matter in coke is due partly to phys. or mech. causes such as occlusion of combustible material by a refractory ash or entrainment of the mineral matter by the steam, but also depends upon the chem. characteristics of the mineral matter of the original combustible. Also in *Riassunto sperimentali eseguiti nell'Officina di Sesto Fiorentino*, Relazione I, Ligniti Xiloidi Toscana. (Livorno 1925). C. C. DAVIS

Examination of coal; the grain size of analytical samples. D. J. W. KREULEN. *Chem. Weekblad* 22, 558-60(1925).—It is advantageous to use finely powdered coal (at least B20 mesh) for the Fischka sulfur detn. The Fischer (Z. angew. Chem. 1899, 564) method for detn. of self-heating tendencies of coal (Br value) depends on the grain size. Const. results can be obtained only for samples finer than B50 mesh.

B. J. C. VAN DER HOEVEN
Method proposed for determination of volatile matter in coal. S. DE WAARD. *Chem. Weekblad* 22, 525-30(1925).—Results are given and detailed description with drawings of the method adopted by the Dutch Institute for Fuel Economy. The errors are limited to 1%. A polished Pt-Ir (3-4%) crucible of 26×30 mm., 12 g., cover 6 g., in a triangle of Ni-Cr with Pt points is placed inside an open cylindrical oven (66 cm. wide). It contains one g. coal (B20 mesh) and is heated by a Meker burner, with gas pressure 38-42 mm., 300 l. per hour, with a flame 18-20 cm. high for 7 min., at 950°. The crucible is allowed to cool in a H_2SO_4 desiccator. B. J. C. v. d. H.

New methods for the examination of gas coal. J. H. STEINKAMP. *Het Gas* 45, 295(1925).—A description of the modification of the Strache method by Mezger and Müller (C. A. 15, 586) for detg. the volatile constituents of coal. R. BEUTNER

Mixing of coal samples and preparation of final samples. D. J. W. KREULEN. *Chem. Weekblad* 22, 560-1(1925).—The American method of mixing (spreading out of coal in a long bed) gives more reliable results than the method in use in Europe (turning the coal pile over). Samples are to be taken of B20 mesh coal. B. J. C. v. d. H.

The purification of coal by foam flotation. D. STAVORINUS. *Het Gas* 45, 266-70 (1925).—A review. R. BEUTNER

Radiation in boiler furnaces. B. N. BROIDO. *Mech. Eng.* 48, 133-8(1926).—Application of water-cooled furnace walls for absorbing heat by radiation is increasing. A certain relation exists between the amt. of fuel burned, the surface exposed to direct radiation in the furnace, and the total heat absorbed by this surface. A standard curve is shown which enables the designer to det. with fair accuracy what part of the total heat generated is absorbed by the water-cooled walls. The heat transmission by radiation per sq. ft. of heating surface for any given furnace condition is obtained

from this curve. The most advantageous arrangement of radiant-heat-absorbing surface for given conditions is suggested. The effect of radiation from gases on heat transmission and the influence of radiation upon the measurement of gas temp. are briefly outlined. A brief discussion is included. W. H. BOYNTON

Pulverized-fuel firing for boilers. R. DE TEMPLE. *Tech.-Ind. Schweiz. Chem.-Ztg.* 1925, 225-34.—A general discussion. W. B. P.

Explosion engines and the liquid-fuel problem (in France). PAUL DUMANOIS. *Bull. soc. encour.* 137, 730-6(1925).—For economic operation, gasoline substitutes such as EtOH, MeOH, C₆H₆, etc., should work at a compression of about 7 (as compared with 5 for gasoline), necessitating certain changes in the engine. Troubles due to self-ignition or to detonation ("knocking") with these fuels can be completely eliminated by addn. of a small proportion of a suitable anti-detonant, e. g., tetraethyl Pb, which also permits of using heavier petroleum products (e. g., gasoline-kerosene mixts.) at higher compression without "knocking" or self-ignition and with appreciably lower fuel consumption. A. PAPINEAU-COUTURE

Iron carbonyl as an anti-detonant. J. H. FRYDLENDER. *Rev. prod. chim.* 29, 1-4(1926).—Brief review of its prepn. and properties. A. PAPINEAU-COUTURE

Recent developments in European gas technology. C. H. S. TUPHOLME. *Gas Age-Record* 55, 701-2, 903-4; 56, 175-6(1925). H. G. BERGER

Malden's new coal-gas plant. R. S. CARTER. *Gas Age-Record* 55, 569-70(1925).—A description. H. G. BERGER

Use of Illinois coal with the pier process. M. P. NOVAK. *Gas Age-Record* 55, 441-4(1925).—See C. A. 20, 104. H. G. BERGER

Water gas from soft coal. L. J. WILLIEN. *Am. Gas J.* 123, 505-6, 516-7(1925); cf. C. A. 20, 105.—Gas analyses (11 tables) are given showing the following: final carbureted gas compn. with and without blow run, and with and without blow run and air purge, both for coke and coke-bituminous coal mixts; effect of blast pressure on final gas when using air purge with coke fuel; blue gas compn. with coke fuel, with and without blow run; gas compn. during blow and blow run for bituminous and anthracite coal; final gas compn. for each run between coalings with bituminous fuel. W. B. P.

The use of bituminous coal as generator fuel. I. L. GILLILAND. *Gas Age-Record* 55, 641-2, 644, 646(1925).—Operating data using W. Va. coal are compared with those from the use of coke and Illinois coal. W. Va. coal gives 30.5 to 54.5% capacity increase and fuel reduction of 1.67 to 3.05 cents per M. as compared to Illinois coal. W. Va. coal has advantages over Ill. coal as to no. of bar downs required. Coke is the cleanest fuel. H. S. PARKER. *Ibid* 899-900.—A discussion of operation. H. G. B.

Determining oil efficiencies in water-gas manufacture. L. J. WILLIEN. *Gas Age-Record* 55, 603-6, 663-6, 668, 670(1925). H. G. BERGER

The heating value of gas. E. R. WEAVER. *Gas Age-Record* 55, 833-4(1925).—The relative usefulness to the consumer of gases of different heating values and the relation to standards and rates are discussed. H. G. BERGER

Stratification of different gravity gases. T. W. WEIGLE. *Gas Age-Record* 56, 171-3, 205-8(1925). H. G. BERGER

Chemical and thermal reactions in generators. J. G. DE VOOCD. *Het Gas* 45, 343-9(1925).—Polemical against Korevaar (C. A. 19, 1622), the result of his calcs. is expressed inaccurately, he should have stated that with a const CO₂:CO ratio high temp. in the generator will result in a low H₂ concn. R. BEUTNER

Liquid fuels and the gas industry. ANON. *Gas World* 83, 8-9(Supplement 1925).—Liquid-fuel production should be taken over by the gas industry and not allowed to become a competitor in other hands. Synthetic NH₃ is cited as a com. undertaking lost to the gas industry. The production of liquid fuels from coal and water gas is discussed. A. E. GALLOWAY

Small by-product oven coal-gas plants. H. J. ROSE. *Gas Age-Record* 56, 5-8(1926).—A description. H. G. BERGER

Determination of specific gravity of gases. Thirteenth report of the Research Sub-Committee of the Gas Investigation Committee of the Institution of Gas Engineers. ARTHUR SMITHELLS, et al. *Gas J* 170, 891(1925).—The differential column method described in *Tech. Paper* No. 5, of the Fuel Research Board was studied. Details are given of the instruments and the methods adopted. Results show that the method is convenient, rapid and yields results correct within ± 0.002 (sp. gr. about 0.5). A crit. review is included of the methods of gas analysis adopted in the course of the investigations. A. E. GALLOWAY

Heating vertical retorts with coal gas. FRANK ELCOCK. *Gas J.* 171, 331-2. *Gas World* 83, 97(1925).—An account is given with data of the change from coke to

gas firing of vertical retorts with great economy of heat and increased profits in the sale of coke.

Waterless gas holders. F. H. WAGNER. *Gas J.* **171**, 336-9(1925).—A waterless gas holder is described and drawings and an illustration are given to show the construction and operation.

Internal corrosion of holders. RICHARD ENGLER. *Am. Gas J.* **123**, 509-10, 519-20(1925).—The method of application of "immunol, a bituminous preparation" for the prevention of the internal corrosion of gas holders is described.

Aeration of lighting burners. Thirteenth report of the Research Sub-Committee of the Gas Investigation Committee of the Institution of Gas Engineers. ARTHUR SMITHIELLS, *et al.* *Gas J.* **170**, 879-91(1925).—A detailed report (with tabulated results) concerned with the degree of aeration of typical low-pressure upright and inverted lighting burners.

Domestic and industrial heating with illuminating gas. F. MUHLERT. *Apparaturbau* **38**, 7-9(1926); 6 cuts.—Description of app. with data on consumption and costs (cf. *C. A.* **19**, 1937, 2405).

The regeneration of absorbing masses. K. F. TROMP. *Het Gas* **45**, 194-205 (1925).—The state of satn. of a mass is detd. approx. by testing its O_2 -absorbing power. In order to test for sulfides an acid soln. of $FeCl_3$ and dimethyl-*p*-phenylene diamine is added; if H_2S is discharged a formation of methylene blue occurs. For a detn of the absorbing power of a mass, the bivalent iron salts and the sulfides are detd. as follows: the mass is dissolved in $FeCl_3$ and HCl , which must be so strong that all the H_2S present is oxidized. After filtering, which removes organic substances, cyanides etc., the soln. is pptd. by KOH . The $Fe(OH)_2$, present in the ppt. is titrated with $K_3Fe(CN)_6$, with dimethyl-*p*-phenylenediamine and phenol as an indicator; this mixt is oxidized to a blue dye by $K_3Fe(CN)_6$. This blue dye, the compn. of which is not known, is distinctly visible although the ppt. in the soln. contg. the $Fe(OH)_2$ is quite dark. During the titration the alky. of the soln. must not be high; O_2 must be absent.

Apparatus for determining the benzene-absorbing power of washing oils. TH. P. L. PETTIT. *Het Gas* **45**, 192-4(1925).—The partial pressure of C_6H_6 over a 3% C_6H_6 soln. in the respective oil is detd. by satg. air with the vapor and burning the $C_{11}H_6$ to CO_2 , which is absorbed by KOH .

Removing lime scales from ammonia distillation columns. TH. HOFFMANN. *Chem. App.* **13**, 17-8(1926); 3 cuts.—The Menzel gas-liquor still is described.

Effluents from ammonia plants and their disposal. T. I. BAILEY. *Gas World* **83**, 48-51 and (Coking Sect.) **83**, 19(1925).—B. discusses NH_3 plant effluents, their origin and possibilities of treating them for the removal of noxious constituents. The storage of ammoniacal liquor effects an enormous drop in sulfides, a large increase in the thiocyanate and thiosulfate, and almost complete disappearance of cyanide. Coke-oven NH_3 plant effluents have a lower O absorption and much lower thiocyanate and thiosulfate than effluents from other plants. The scrubbing of liquors at 95° by flue gases reduced the phenol content to 0.71%. A liquor rich in NH_3 and relatively low in thiocyanate and thiosulfate would be obtained were the crude coal gas leaving the hydraulic main submitted to shock cooling with prompt removal of the condensed liquor for storage out of contact with air.

Treatment of effluent spent liquors from the distillation of ammoniacal liquor. II. T. I. BAILEY. From the Report for 1924 under the Alkali Works Regulation Act. *Gas J.* **171**, 282-5(1925); cf. *C. A.* **17**, 1129.—The progress made in treatment of liquors is reported. The discussion centers about the 4 sources of pollution; phenol, thiocyanate, thiosulfate and color-producing substances and other compds. Causes and effect of treatments with data to show the compn. of the liquors are given.

Low-temperature carbonization as a commercial process. WM. H. BLAUVELT. *Chem. Met. Eng.* **32**, 925-7(1925).—A general discussion of the economics of low-temp. carbonization in the U. S., with particular emphasis on the field available for semi-coke as a domestic fuel.

The rationale of coal carbonization. I. The carbonizing problem as it stands today. WM. E. DAVIES. *Gas World* **83**, 157-62. II. *Ibid* 176-9.—A comprehensive review.

Carbonization research in Australia with a continuous vertical retort. R. E. THWAITES AND J. PACKER. *J. Soc. Chem. Ind.* **44**, 519-25T(1925).—Expts. with a continuous, vertical (Thwaites) retort, for tests lasting 6, 3.5 and 5 weeks on Australian

caking coals, are described in detail. Mechanical difficulties are blamed for poor success in treating these caking coals in narrow, externally heated retorts, as the charge sticks in the retort and has to be poked down very often. W. C. EBAUGH

Combustibility and mechanical strength of furnace coke. F. HÄUSSER. *Stahl u. Eisen* 45, 878-85(1925); cf. C. A. 17, 3092.—The combustibility of coke is calcd. from the formula $(\text{CO}_2 + \text{CO})/2\text{O}_2$, from the analysis of the products of combustion in large-scale expts. The duration of combustion, size of furnace, nature of coal producing the coke and Fe content of the coke have only a small effect on the combustibility, which depends largely upon the size of the coke particles, increasing rapidly with decrease in size. The chief factor influencing the resistance of the coke to crushing and abrasion is the degree of fineness of the coal carbonized, the strongest coke being produced from the most finely ground coal. A study of the coke used in furnace practice shows that the strength of the coke is considered rather than the combustibility. B. C. A.

Coke ovens in a Canadian gas works. J. STEPHENSON. *Gas Age-Record* 56, 563-6, 574(1926). H. G. BERGER

Gas firing of retorts and coke production. ANON. *Gas World* 83, 134-5(1925).—A discussion of retort firing with gas and with coke. Instances of each type of firing are cited with a saving of heat in each case. Conclusion: Neither type of firing can be used to the exclusion of the other and the one to be used must be detd. by the economic conditions, etc. A. E. GALLOWAY

Catalytic formation of methane from CO and H (CHAKRAVARTY, GHOSH) 2.

WELLINGTON, S. N. and COOPER, W. R.: **Low Temperature Carbonization.** Philadelphia: J. B. Lippincott Co. 238 pp. \$9.50. Reviewed in *Chem. Met. Eng.* 32, 942(1925).

Burning powdered or gaseous fuels. H. ADAMS. U. S. 1,571,179, Feb. 2. Air or steam is projected substantially in the line of projection of burning fuel and under higher velocity than that of the fuel, so that burning fuel and gases are drawn along for controlling the combustion and for directing the heat generated, *e. g.*, for heating reverberatory furnaces.

"Anti-knock" liquid fuel. T. MIDGLEY, JR. U. S. 1,571,862, Feb. 2. A fuel ingredient adapted for use in internal-combustion engines comprises aniline 6, "unsatd. gasoline" 3 and a blending agent such as *o*-toluidine and xylydine 2 parts.

Fuel briquets. E. EDSEER and MINERALS SEPARATION, LTD. Brit. 235,634, March 18, 1924. Finely divided carbonaceous fuel suspended in H_2O is agitated with an emulsion of residuum from distn. of Mexican fuel oil or other bituminous material preferably heated to 60-100° to cause flocculation, and pressed to remove H_2O and form briquets.

Fuel briquets from peat. L. RUDEMAN. Brit. 236,366, June 25, 1924. The H_2O content of peat or a mixt. of peat and peat earth is reduced to 60-65% and the material is then agitated with waste sulfite liquor contg. phenols or with tar oils under the action of heat and pressure and formed into briquets. Coal or coke dust, tar and other fuel ingredients also may be added.

Drying peat with steam under pressure. W. DONALD. Brit. 235,607, July 9, 1924. An app. is described.

Treating coal for fuel. L. A. WOOD and MINERALS SEPARATION, LTD. Brit. 234,855, Feb. 29, 1924. Finely divided coal is agitated with aeration in aq. suspension with fine pitch so that a coal-pitch-froth is formed and sepd. from the bulk of the H_2O and gang. An aq. pulp of this mixt. is then heated with or without a flocculating agent to flocculate the coal particles which may then be briquetted. Various modifications and details are described.

Distillate from coal, etc. A. G. BLACK. Brit. 234,864, Jan. 30, 1924. Coal, shale, pelionite lignite and similar materials are rapidly heated in a closed retort from

which gases are withdrawn downwardly and delivered to a pipe leading at one end to a receiver and at the other end to a filter to retard passage of heavy vapors and permit passage of light vapors and gases. Gases and light products pass to a condenser and second filter and fractional condensation is effected.

Liquid products from coal. M. MELAMID. Brit. 235,828, June 17, 1924. Liquids for use as *fuels* or in *lubricating* are obtained by heating coal, lignite or similar materials at atm. or higher pressures in a protective atm. with metal catalysts having a m. p. below the reaction temp. A temp. of 300-600° is suitable and H_2O , mineral oils or tar oils may be added to the coal. The mixt. may be treated with H , CH_4 or steam in a Sn-lined vessel contg. Sn or Sn alloys.

Gasification of coal. K. P. McILROY. U. S. 1,571,877, Feb. 2. A vertical column of bituminous coal with a carbonized base is maintained, the base is blasted with hot air at a temp. at least sufficient to fuse and run ash components as slag, a regulated portion of the hot gases is withdrawn from the base and filtered through C and the heat of the filtered gases is transferred to the air used for blasting.

Purifying fuel gases. J. W. COBB and H. J. HODSMAN. U. S. 1,571,624, Feb. 2. Fuel gases are subjected to the action of Fe oxide or other contact materials which will effect partial oxidation of H_2S under conditions of temp. and humidity which will ensure that the free S formed shall be carried forward from the contact material. NH_3 is used to effect removal of SO_2 (present in the gas after the partial oxidation of the H_2S) by the subsequent condensation and washing operations and the NH_3 content of the gas is adjusted to ensure the removal of the acid compds. contg. S and O.

Purifying gas. KOPPEKS Co. Brit. 235,125, June 6, 1924. In removing H_2S and other impurities from coal gas or like gases, the impurities are transferred from the gas to a stream of air which is then washed with liquid contg. freshly pptd. Fe oxide. The reaction between the fouled air and the washing liquid is effected while both are moving in the same direction. An app. is described. Brit. 235,126 relates to a process in which about 90% of the H_2S is removed from gas by treating it with a Na_2CO_3 soln. and this soln. is then treated with air to revivify it. The air carrying H_2S is treated with a dil. Na_2CO_3 soln. contg. freshly pptd. $Fe_2(CO_3)_3$ and this soln. is regenerated as in Brit. 235,125. Brit. 235,127 specifies recirculating air from which impurities have been removing by the washing liquor with the stream of air to which impurities from the gases are transferred and also describes an app. for the gas purification process.

Water gas. A. G. GLASGOW. Brit. 234,929, March 13, 1924. Steam is superheated by passage in the reverse direction through the usual regenerative chambers and is used for an "up run" by being passed into the bottom of the generator. Resulting gases are passed off from the top of the generator to a holder without passage through the regenerative chambers.

Water gas. J. RUDE. Brit. 235,007, June 18, 1924. In producing water gas in externally heated retorts, steam is admitted to the charge at various points and levels of the retort and gases may be removed as formed. Various details of app. are specified.

Water gas. C. MARISCHKA. Brit. 236,579, July 5, 1924. The "blow" is burned in a superheater and the products are passed through a heating jacket surrounding an annular boiler forming part of the producer. Various other details of operation and of app. employed are also described.

Carbureted water gas. WOODALL-DUCKHAM (1920), LTD. and D. RIDER. Brit. 235,693, May 17, 1924. The products of oil cracked in the carburetor during the "blow" are introduced with the steam passed into the generator during the "run." App. details are described.

Apparatus for making carbureted water gas. T. F. HOLDEN. Brit. 235,427, Sept. 3, 1924. An app. is specified for making gas according to a process also involved in Brit. 235,428. A series of up and down runs produces gas in a generator and the gas formed is passed through an economizing chamber formed in the side of a carburetor to a primary mixing chamber where the gas is divided into streams by a wall which preheats the carbureting liquid.

Gas producer operation. POWER-GAS CORPORATION, LTD. and N. E. RAMBUSH. Brit. 235,958, March 26, 1924. A mixt. of water gas and coal gas (with a high yield of low-temp. tar, NH_3 and coke) is obtained by gasifying bituminous fuel so that semi-coke is formed in the lower zone of the fuel column and maintained incandescent by withdrawing it continuously at such a rate that up-streaming only can be maintained without displacing upwardly the incandescent coke. An app. is described.

Producer gas and water-gas plant. A. BREISIG. Brit. 235,891, June 18, 1924.

Gas producer with a rotary hearth. L. TREFOIS. Brit. 236,185, June 24, 1924.

Water-gas producer. J. RUDE. Brit. 235,087, Nov. 21, 1924.

Portable gas producer for use with internal-combustion engines. R. I. DENHAM and N. C. JONES. Brit. 235,045, Aug. 14, 1924.

Device for uniform charging of fuel into gas producers, etc. L. TREFOIS. Brit. 236,184, June 24, 1924.

Baffle and filter apparatus for cleaning producer gas. C. W. THORNE and FEROLITE, LTD. Brit. 235,987, April 9, 1924.

Gas bench and retort construction. H. J. TOOGOOD and R. DEMPSTER & SONS, LTD. Brit. 234,947, April 3, 1924.

Hydrogenating tar oils. W. DEMANN. Brit. 236,230, June 30, 1924. Tar oils are hydrogenated at ordinary pressure and elevated temp. by the use of coke-oven gas which has been previously dehydrated by refrigeration or treatment with CaCl_2 or with H_2SO_4 . At the temp. of the hydrogenation ($180\text{--}200^\circ$) the H_2O formed by the reaction is removed by the gas current. The tar oils are preliminarily desulfurized with Fe sulfate or Rasen Fe ore. A colloidal Ni catalyst may be used to facilitate the hydrogenation.

Purifying anthracene. VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Brit. 236,170, June 28, 1924. The process of Brit. 233,734 (C. A. 20, 768) is modified by adding to the reaction mixt. lime or other alk. earth oxide or other substance capable of combining with H_2O under the prevailing conditions. A solvent b. $220\text{--}260^\circ$ may be used when lime is added.

Drying coal for coking. S. R. ILLINGWORTH and ILLINGWORTH CARBONIZATION CO., LTD. Brit. 235,627, March 17, 1924. A portion of wet coal, previous to coking is heated out of contact with air and mixed with another wet portion to form a mixt. contg. over 5% resinic substances and preferably 3% H_2O . If different coals are mixed, the coal of lower resinic content is preferably heated and mixed with the coal of higher resinic content. An app. is described.

Metallurgical coke from bituminous coal. J. C. JOLLY and R. V. WHEELER. Brit. 236,002, May 1, 1924. Bituminous coal for coking is mixed with a material which when heated will produce a high proportion of H or other reducing gas and which at $400\text{--}600^\circ$ will effect no binding or agglomerating action on the material. Anthracite or semi-anthracite coal, semi-bituminous coal as mined or weathered, bituminous coal after weathering or carbonizing below 600° or peat or lignite which may have been carbonized below 600° may be used. The material should have a S content not exceeding 1%.

Coking bituminous coal. ALLGEMEINE VERGASUNGS-GES. Brit. 236,151, June 24, 1924. Bituminous coal is first heated to a temp. below that at which it becomes pasty, e. g., at 325° , for a sufficient time to remove all substances volatile at that temp. preparatory to subsequent coking. Vertical retorts and an upward current of hot inert gas may be used for this treatment.

Plant for dry-cooling hot coke, and utilizing its heat. A. MOETTEL. U. S. 1,571,455, Feb. 2. Heat from the coke may be utilized for heating boilers.

Rectification and liquefaction system for obtaining hydrogen from coke oven or illuminating gas, etc. SOCIÉTÉ L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS G. CLAUDE). Brit. 235,129, June 3, 1924.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Progress in the mineral oil industry in 1924. R. KISSLING. *Chem. Umschau Fette, Öle, Wachse u. Harze* 32, 285-90, 297-303 (1925).—A general review with numerous references and a book list of 24 new titles. P. ESCHER

Sulfur compounds removed from Persian petroleum by means of sulfuric acid. I. B. H. THIERRY. *J. Chem. Soc.* 127, 2756-9 (1925).—By strong diln. of 12 l. of H_2SO_4 sludge from the refining of a Persian petroleum and removal of the sepd. oil, followed by extn. of the aq. mixt. with CHCl_3 , the total yield is 1.8 l. of oils. Repeated fractionation gave 8 fractions b_{760} $50\text{--}100^\circ$ and 21 fractions b_{128} $60\text{--}120^\circ$, of which 4 were

examd. thoroughly. The fraction b_{760} 68–70° contained 60% CHCl_3 remaining from the extn. and 40% MeEtS ; that b_{760} 89–92° was apparently a mixt. contg. mainly MePrS or iso- PrMeS , its quantity not being sufficient to permit complete identification. The fraction b_{125} 63–6° (after further fractionation b_{760} 120–1°) was mainly tetramethylene sulfide; that b_{125} 81–4° (after further fractionation b_{760} 138.5°) was mainly pentamethylene sulfide. These compds. were identified by their MeI , HgCl_2 , H_2PtCl_6 and sulfonium iodide mercuriiodide derivs. W. B. PLUMMER

Chemical nature of the crude oil of Gbely. R. VONDRÁČEK. *Petroleum Z.* 21, 1035–40 (1925).—The oil has the following characters d. 0.9407, viscosity (Engler) at 50° 2.98, closed flash pt. 102°, hard asphaltum none, soft asphaltum 0.05%, paraffin wax none, I value 19.2, ash 0.080%, C 87.5%, H 11.96%, N 0.18%, S 0.12%, gross heat value 10,600 cals. H_2SO_4 of d. 1.84 reacts with the crude oil with evolution of heat, but has little action on the lightest fractions. The oil is very nearly akin to that of Louisiana. The following mol. wts. and formulas were found for various fractions: d. 0.865, 166 to 180, $\text{C}_{12}\text{H}_{24}$ or $\text{C}_{13}\text{H}_{24}$; d. 0.915, 216 to 260, $\text{C}_{13}\text{H}_{26}$ or $\text{C}_{14}\text{H}_{28}$; d. 0.935, 272 to 286, $\text{C}_{20}\text{H}_{42}$ or $\text{C}_{21}\text{H}_{44}$; d. 0.957, 366 to 380, $\text{C}_{27}\text{H}_{54}$; d. 0.969, 512, $\text{C}_{40}\text{H}_{82}$. Many of the hydrocarbons found in this oil are of similar compn. to those obtained by the extn. of coal with pyridine. An attempt to fractionate the oil by soln. in pyridine gave fractions as follows: d. 1.008, mol wt. 316, $\text{C}_{23}\text{H}_{46}$; d. 0.956, 291, $\text{C}_{21}\text{H}_{42}$; d. 0.922, 317, $\text{C}_{23}\text{H}_{46}$, with in each case, the fraction of an atom of O. The crude oil contains water, which is removable only in part and with difficulty by settling B. C. A.

Naphthenic acids derived from gas-oil distillate of Californian petroleum. YOSHIO TANAKA AND SHOICHIRO NAGAI. *J. Soc. Chem. Ind. Japan* 29, 1–7 (1926).—By acidifying a waste lye produced in the refining of gas oil of the mixed oil from Long Beach and Santa Fe Spring fields in California, crude petroleum acid has been obtained, having d_4^{15} 0.9972, n_D^{15} 1.4979 and acid value of 51.2. Crude naphthenic acids (d_4^{15} 0.9797, n_D^{15} 1.4927 and acid value 191.4) were sepd. from the petroleum acid, and were changed into Me esters, d_4^{15} 0.9535, n_D^{15} 1.4806, 81% of which b_{8-9} 160–230°. The esters were sapond. into pure mixed naphthenic acids, d_4^{15} 0.9773, n_D^{15} 1.4893 and neutralization value 208.4. They distd. under 8.9–9.0 mm. at 136–260°, 82°C° under 8.9–9.0 mm at 200–260° with d. 0.976–0.985. The fraction at 210–220° had a max. sp. gr. 0.985. The sp. gr. (0.976–0.985) of the main fraction is a little lower than that (0.99) of naphthenic acids derived from the petroleum of Kurokawa origin (*J. Soc. Chem. Ind. Japan* 25, 1031–44 (1922)) and a little higher than that (0.97) of the acids from the petroleum of Nishiyama origin (*J. Soc. Chem. Ind. Japan* 27, 446–55 (1924)). There are two series of naphthenic acids having isomeric compn. which are differentiated chiefly by the sp. gr. The naphthenic acids here obtained are probably a mixt. of the two series of the acids. A white cryst. mass sepd. from the fractions of high. b. p. K. K.

Industrial requirements for dry-cleaner's naphtha. L. E. JACKSON. *Ind. Eng. Chem.* 18, 237–8 (1926).—A brief discussion of various dry-cleaners is followed by a specification for petroleum naphtha (gasoline) suitable for the purpose. The b. p. should range from 137.8° to 204.5°; unsatd. hydrocarbons should be low, undissolved water and suspended matter and aromatic hydrocarbons should be absent; the acidity and doctor tests should be negative. W. H. BOYNTON

Shale research. A. HALLBACK. *Tekn. Tids* 55 (Kem. afd.), 57–62, 67–8 (1925).—A report on the progress of research on shale under the direction of the Engineering Academy. A. R. ROSE

Distillation tests on West Goth shale. W. PALMAER AND E. NORLIN. *Tekn. Tids* 55 (Kem. afd.), 89–92 (1925).—Mostly tables. A. R. ROSE

Refining shale oil in Scotland. G. F. MCKILLOP. *Chem. Eng. Mining Rev.* 18, 101–2 (1925). E. H.

Oil shale and its uses. A. SANDER. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 281–2 (1925).—S. describes the efforts made in Estonia of utilizing oil shales which contain up to 24% of oil. Gasification expts. proved uneconomical but low temp. distn. is promising and yields up to 91% recovery. Much of the shale is used directly as fuel in place of coal in the industries and on locomotives. P. ESCHER

Control of technical production of oil-gas. W. GOLUB. *Nefljanoe slancevoje Chozjastvo* 7, 725–9 (1924).—Expts. on the thermal decompn. of petroleum in the University exptl. plant at Saratov are described. The temp. is kept at 800–900° and is regulated by an alteration in the heating and not by the rate of flow of petroleum. This rate is fixed empirically and the course of the process is followed from the gas meter reading. If the retort is filled with steel shavings the gas yield is in-

creased. The compn. of the gas also changes, CH_4 partially replacing the H_2 .

B. C. A.

Report of the surgeon general's committee on tetraethyl lead. W. H. HOWELL, *et al.* *Ind. Eng. Chem.* **18**, 193 6(1926).—No evidence of Pb absorption or storage has been found in drivers of cars operating on "ethyl gasoline" (PbEt_4 /gasoline ratio 1/1300) for a period of 2 years' exposure. Filling station and garage employees, for the same period of exposure, showed slight absorption in tests of the feces and blood, but in no case were any detectable symptoms of Pb poisoning produced. Despite the distribution of about 300,000,000 gals. of "ethyl gasoline (between Feb., 1923 and May, 1925) no recognizable cases of Pb poisoning or other disease arising from its use have been observed. The manuf. of PbEt_4 and the distribution of "ethyl gasoline," both under regulated conditions, are safe as far as can be detd.

W. B. PLUMMER

Petroleum asphalt and petroleum tar. A. SACHANOV. *Nefljanije slancevaje (hozjajstvo)* **7**, 933-53(1924).—The asphaltene content of various products varied from 0.25% in Grosny petroleum free from paraffins, to 32.3% in solid petroleum pitch. The products from the different sources contained C 85.5%, H 6.8%, O 7.7%, and some S, had d 1.145, and possessed similar properties. The properties of asphaltene from petroleum pitch were unchanged after blowing air through the pitch at 350°, but the asphaltene content rose from 13.7 to 32.3%. Asphaltenes are sol. in aromatic hydrocarbons, CHCl_3 , CCl_4 , and light petroleum, soln. being preceded by a swelling of the material, and resulting in the production of viscous solns. Asphaltenes are lyophilic colloids with respect to aromatic hydrocarbons, terpenes, halogenated hydrocarbons, CS_2 and petroleum tars, the colloidal solns. being highly dispersed and stable, comparable with aq. gelatin solns. Natural asphalt and petroleum pitch are colloidal solns. of asphaltenes in tars and heavy oils. Soln. of asphaltenes in the above solvents is exothermal, the heat of soln. in toluene being about 10 cal. per 1 g. Asphaltenes are lyophobic with respect to paraffin hydrocarbons and naphthenes. Rubber acts as a protective colloid towards asphaltenes, and prevents their flocculation in soln. The coagulation of asphaltenes is reversible. The relationship between asphaltenes and petroleum depends upon the content of lyophilic or lyophobic constituents. In cases where the lyophobic constituents predominate, as in Russian petroleum and masut, the asphaltenes are present mostly in the disperse state; on the other hand, Californian and Mexican petroleum and petroleum pitch contain a high proportion of tar which is lyophilic to asphaltene. The low soly. of asphaltenes in light petroleum fractions is caused by the presence of lyophilic solvents, such as aromatic hydrocarbons. During coagulation, asphaltenes readily absorb tar, and the properties of the material are affected considerably thereby. The soft asphaltenes described by Holde are asphaltenes contg. varying quantities of adsorbed tar. To sep. asphaltenes from adsorbed tar, the mixt. is dissolved in the smallest possible quantity of benzene or CHCl_3 and asphaltenes are pptd. by the addn. of light petroleum, the process being repeated once or twice as necessary. Paraffins sol. with difficulty, which are often pptd. together with asphaltenes, can sometimes be sepd. by the same method, but if it fails, the material must be extd. with boiling alc. or light petroleum.

Liquid products from coal (Brit. pat. 235,828) **21**. Filter for gasoline (Brit. pat. 235,812) **1**. Distillate from coal, etc. (Brit. pat. 234,864) **21**. Purifying oil (Brit. pat. 234,886) **27**. Fractionating tower for distillation of oil (U. S. pat. 1,571,805) **1**.

LEVI, GEORGES: *Éléments de la technique du pétrole*. Paris: l'Université de Strasbourg, l'Institut du Pétrole. 97 pp.

Petroleum from oil sand deposits. P. DE CHAMBRIER. Brit. 234,979, May 16, 1924. After extg. from oil sands all oil obtainable by pumping or natural flow, galleries are formed through the oil sands from the foot of 1 or more shafts and gas is drawn off by aeration or ventilation, causing oil and gas emulsions to break down and oil to flow into the galleries.

Cracking hydrocarbon oils. MOTOR FUEL CORPORATION. Brit. 235,564, June 16, 1924. Heavy oils such as fuel oil or kerosene distillate are heated to a cracking temp. under sufficient pressure to maintain them in liquid phase, cooled to about normal temp. while still under pressure and the pressure is then released to permit escape of permanent gases. The remaining oil is distd. by heat exchange with the heated oil. An app. is described.

Purifying oils. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 235,861, June 23,

1924. Spent lubricating oil is treated with a resinate which may be prepd. by melting resin with an oxide of Mn, Cu, Pb or Zn and may be used in the form of a soln. in C_6H_6 or other solvent, with or without addn. of a small quantity of stearic acid. Sol. silicate is then added and the mixt. is floated on the surface of H_2O heated to 80° so that a sludge of impurities seps.

Distilling oil shale. JACKSON RESEARCH CORPORATION. Brit. 236,420, Sept. 23, 1924. Oil shale or similar material is heated to $500-600^\circ$ in an externally heated vertical retort with a perforated bottom beneath which there is a gas-collecting chamber whence liquid and vapor are withdrawn to a sepg. tank. Uncondensed gases may be returned, together with additional inert gases, to the top of the retort.

Oil gas. P. HAHN. Brit. 235,625, March 17, 1924. Liquid fuel, after preliminary vaporization, is passed through a series of nozzles formed by overlapping baffle plates in a heated chamber and may then be mixed, after complete gasification, with steam, O_2 or O_3 . Air is drawn into the app. described by suction nozzles.

Filtering hydrocarbon lubricating oils. F. W. HALL. U. S. 1,570,890, Jan. 26. Oil, substantially free from H_2O , is filtered upwardly through a mass of adsorbent clay, to produce a "water white" product suitable for medicinal use.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Detection of bleach damages by means of the copper number determination. HERMANN WENZL. *Wochbl. Papierfabr.* 56, 994-7, 1024-7 (1925).—The over-bleaching of fibers by mildly alk. hypochlorite solns. is shown equally well by the Cu no. detn. or the fiber-strength test. When the bleaching process occurs in a strongly alk. soln., such as in the case of Na_2O_2 , the alkali exerts a solvent action on the oxidized cellulose and the Cu no. is small, but the fiber strength is markedly decreased. The Cu no. detn. is thus considered unsuitable as a criterion for over-bleaching. The Braidy Cu no. procedure possesses no advantages over the Schwalbe procedure, which by using the Hägglund titrimetric method is recommended as the most rapid and reliable one to use. The decompn. of Fehling soln. may be almost entirely prevented by using pure reagents and an app. which does not lead to over-heating (cf. Bray and Liu, C. A. 19, 2129). The Kaufmann $KMnO_4$ no. is unsuitable for pulps. J. L. PARSONS

Observation on the cellulose and paper industry in U. S. A. OLOF OLSON. *Tekn. Tids.* 55 (Kem. afd.) 66-7 (1925). A. R. ROSE

Physicochemical study of cellulose fibers. ROGER BOUSSU. *Pulp Paper Mag. Can.* 23, 1505-6 (1925).—See C. A. 20, 287. A. PAPINEAU-COUTURE

Waste liquor and gases of the paper industry. A. SCHROHE AND C. J. WEST. *Paper Trade J.* 81, No. 14, 62-4; No. 15, 55-6; No. 17, 56-8; No. 18, 106-8; No. 19, 57-9; No. 20, 54-6; No. 21, 57-8; No. 22, 55-6; No. 23, 61-3; No. 24, 50-2; No. 25, 47-50; No. 26, 50-2 (1925).—Translation of Schrohe's article (C. A. 19, 2564) supplemented by numerous references which raised the number of patents from 202 in the original to 534 in the translation. A. PAPINEAU-COUTURE

The bleaching of papermaking pulps under pressure. M. J. BOEHM. *Paper Ind.* 7, 1421 (1925).—Sulfite can be bleached in an hour at about $70^\circ F.$ in closed rotating bleaching vessels, under the slight pressure developed by the chem. action. With a 4000-5000 lb. batch, only 6-8 h. p. is required. A. PAPINEAU-COUTURE

Durability of writing paper. S. KÖHLER AND G. HALL. *World's Paper Trade Rev.* 84, 1610-4; *Paper Makers' Monthly J.* 63, 419-21; *Paper Mill* 49, No. 50, 14, 16 (1925); cf. C. A. 19, 2745; 20, 288.—Tests carried out at the Swedish Govt. Testing Institute, Stockholm, show that: (1) the tensile strength is increased and the elongation decreased on increasing the speed at which the Schopper tester is run; (2) no difference in folding resistance is observed on running the machine at 80 and 110 double folds a min., and an increase of about 5% on running it at 140 double folds a min.; (3) better agreement is obtained in the detn. of tensile strength than in the detn. of folding resistance; (4) under the action of light or heat or both the folding resistance of paper made from bleached sulfite decreased much more rapidly than that of unbleached or bleached cotton or linen rag paper; (5) increase in the Cu no. of the fibrous material probably reduces the durability of the paper; (6) rosin sizing causes a decrease in the folding resistance and an increase in the acidity of the paper as compared with unsized paper; (7) deterioration in durability due to rosin sizing is probably not sufficient to render rosin sizing unsuitable for paper intended for keeping indefinitely, provided excess

of $\text{Al}_2(\text{SO}_4)_3$ is avoided; (8) $\text{Al}(\text{AcO})_3$ does not seem to present any advantage over $\text{Al}_2(\text{SO}_4)_3$ from the standpoint of durability of the paper; (9) sizing with animal glue increases the folding resistance as compared with unsized paper, but the increase is lost comparatively rapidly on exposure to light or heat or both and on storing at ordinary temp.; (10) the degree of acidity of tub-sizing within the limits generally accepted in practice has little or no effect on the durability of the paper; (11) loading with a mixt. of china clay, gypsum, chalk, agalite and Swedish talcum has a beneficial rather than detrimental effect on the durability of the paper. A method for detg. acidity is described (cf. K hler and Hall, *C. A.* 20, 286). A. PAPINEAU-COUTURE

Coated paper. G. K. HAMMILL. *Paper Mill* 49, No. 50, 18-9, 38-9 (1925).--A discussion of paper coating, bringing out the advantages of glue as an adhesive, as compared with casein, provided it is used under suitable conditions. A plea is made for co peration between the ink mfr., paper mfr. and printer. A. PAPINEAU-COUTURE

Application of dyeing to the reconstitution of washed (bleached) writing. R. MELLET AND M. A. BISCHOFF. *Compt. rend.* 181, 868-9 (1925).--On dyeing paper from which the writing has been removed by bleaching (generally with hypochlorites followed by washing with acid), the dye will be absorbed differently by the body of the paper and by that portion which had been covered by the writing. This is attributed to the fact that the ink protects the underlying paper for a certain time from the action of the hypochlorite, resulting in less superficial oxidation of the paper, which in turn involves a difference in affinity for the dye. The difference is masked by the intense adsorption of the dye by the filler, and is brought out by examn. with a Woods lamp (ultra-violet light suitably filtered). A. PAPINEAU-COUTURE

Papier m ch  compositions. A. LAMBRETTE. *Industrie papeti re* 4, 273-5, 302-8, 337-40 (1925).--Various formulas and processes are outlined. A. P.-C.

Comparison of heart and outer wood for paper making. E. HAGGLUND AND S. HANSEN. *Acta Acad. Aboensis Math. Phys.* 3, 45 pp. (1923).--The fiber of outer wood is longer than that of heart wood, but no appreciable differences in the yield or strength of paper, prepd. by the sulfite process, were found; it is possible that the ratio of length to width of fiber is important. Hydrated cellulose products. C. F. CROSS and VISCOSE DEVELOPMENT CO., LTD. Brit. 236,336, May 12, 1924. To prevent or control the shrinkage of hydrated cellulose products, e. g., artificial silk, films or bottle caps, the H_2O of hydration is displaced by glycerol and absorbed by deliquescent salts incorporated with the material, e. g., ZnCl_2 admixed with Zn acetate, or CaCl_2 or MgCl_2 .

Dissolving cellulose with hydrochloric acid. A. CLASSEN. Brit. 236,281, April 2, 1924. See U. S. 1,570,553 (*C. A.* 20, 822).

Composite sheets of casein and cellulose esters or ethers. SOC. ANON. L'OYON-NAXI NNE, FABRIQUE DE MATI RES PLASTIQUES. Brit. 235,350, April 28, 1924. Sheets are formed with alternate layers of casein and of a cellulose nitrate, acetate, xanthate or ether, united by the use of a solvent and of heat and pressure.

Acetic acid recovery from cellulose acetate solutions. VERREINIGTE GLANZSTOFF-FABRIKEN AKT.-GES. and F. PASCHKE. Brit. 235,727, July 3, 1924. A soln. of cellulose acetate contg. HOAc is mixed with a satd. soln. of NaOAc, KOAc, MgSO_4 or other suitable salt to form a jelly and this is then gently pressed to sep. liquid rich in HOAc. The jelly is repeatedly moistened and pressed to effect further sepn.

Coating cardboard and similar materials. H. FRIEDL NDER. Brit. 236,224, June 26, 1924. A substitute for ebonite, hard paper, etc., is prepd. by impregnating cardboard, felt, papier-m ch  or other fibrous material with carnauba wax, "mountain wax" or mixts. of these with resin or metallic salts or other auxiliary hardening agents, under vacuum or pressure.

Apparatus for producing acid liquor for sulfite pulp processes. J. D. J NSSEN U. S. 1,571,271, Feb. 2. A heater and mixer is placed between 2 towers for treating the liquor as it passes from one tower to the other.

Paper-making machine. A. ALDRICH. U. S. 1,571,362, Feb. 2.

Beating apparatus for making pulp from paper, rags, etc. E. B. FRITZ. Brit. 235,626, March 17, 1924.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

The influence of gases and inflammable and noninflammable vapors on the limits of explosibility of mixtures of gas and air. VI. Graphic representation. W. P. JORISSEN. *Rec. trav. chim.* **44**, 1039-47(1925).—Le Chatelier (*Ann. mines* [8], **19**, 393(1891)) in studying the inflammability of firedamp observed that when n and n' are the vols. of two combustible gases mixed with a sufficient amt. of air to make a total of 100 vols., and N and N' are the limits of inflammability of the 2 resp. gases then when the limit of inflammability is reached the relation, $(n/N) + (n'/N') = 1$, will exist. This formula has been applied with good success many times. The results of Coward *et al.* (*C. A.* **13**, 1150), of Price (*C. A.* **14**, 1043) and of White (*C. A.* **17**, 470; **19**, 1197) especially are reviewed in this connection. If the proportions of the 2 gases or inflammable vapors in the mixt. are taken as coordinates Le Chatelier's formula is the equation of a line. The segments that this line intercepts on the axes are the explosion limits of the gas or vapors taken alone. In the case of $C_2H_2 + CO$ and $H_2 + CO$ a straight line is obtained. This is nearly true for $CH_4 + H_2$ but with $C_2H_4 + H_2$ and $NH_3 + H_2$ interesting deviations begin to appear. Some of these results are also taken from previous papers in this series (J. *et al.*, *C. A.* **18**, 2251; **19**, 178, 2274, 3595). They are all given in 12 graphs. In general the results show that this graphical representation of the results (cf. also White, *l. c.*) is a more practical and instructive means of studying the results than tabulated data. E. J. WITZEMANN

Application of stone dust in coal mines. ALLAN GREENWELL. *Safety in Mines Res. Bd., Paper No. 2*, 4-58(1923).—This paper records the information now available on the application of incombustible dusts in coal mines to prevent the spread of coal-dust explosions. After an historical review the subject is treated in detail under the following headings: (1) methods of distributing stone dust; (2) methods of sampling the dust mixts.; (3) results of the application of stone dust as shown by sampling; (4) prepn. of stone dust; (5) character of various stone dusts; (6) lab. work. The last section is of special value to chemists who may have to deal with dusts and especially with grain size. A review of this collated material shows that divergent opinions or doubt exists as to the manner of application of the incombustible dust, the manner of sampling the dust on the roadways for analysis, and the manner of the analysis itself. It is held that the coal dust mixt., to prove effective as a preventive of spread of explosion, must contain at least 50% of ash, and that a method of analysis which gives the ash content within 2% of the actual content is as accurate as the method of sampling.

CHARLES E. MUNROE

Coal dust explosions. G. S. RICE. *Trans. Am. Inst. Min. Met. Eng.*, Feb., 1925 (advance copy), 32 pp.—The history of investigations since 1801 into the cause of coal mine explosions is reviewed, with mention of the chief disasters in England, America, France and Germany and it is shown how the varying opinions in these countries at different times concerning the possibility of explosions being due to coal dust alone affected the steps taken to diminish the risk of explosion, whether by watering the roadways, by stone dusting, or by regulating the compn. of the explosives used. The establishment of exptl. galleries for the investigation of the conditions under which coal dust would explode, or for the testing of explosives proposed for use in mines is then described with special reference to the work carried out at Altofts and Liévin and by the U. S. Bureau of Mines. For stone dusting the Bur. of Mines suggests that not less than 2-3 lbs. or preferably 4 lbs. per linear foot should be used, and that the dust should not contain more than 25% of free silica when used in places where it is liable to get into air breathed by miners. For this reason the use of pure limestone, gypsum, or dolomite is advocated.

B. C. A.

Lag on ignition of firedamp. C. A. NAYLOR AND R. V. WHEELER. *Safety in Mines Res. Bd., Paper No. 9*, 3-16(1925).—An essential condition for ignition of a mixt. of CH_4 and air is that the source of heat, besides being of sufficient temp., shall remain in contact with the mixt. during a sufficient length of time. This "lag" on the ignition of CH_4 has an important bearing on safety in coal mining. It accounts for the fact that it is very difficult to cause an external ignition of CH_4 by the gauze of a miner's flame lamp heated by CH_4 burning within it; and it provides grounds for the

belief that it should be possible to compd. explosives having flames of such brief duration that, despite their high temps., they could not ignite CH_4 . With many tables of data and graphs from them the subject is reviewed for mixts. of paraffin hydrocarbons with air, from CH_4 to C_8H_{18} . The exptl. methods used are described in detail and the app. is illustrated. The lag on ignition is of shorter duration the higher the temp. of the source of heat above the ignition temp. of the mixt. A mixt. contg. 6.5% CH_4 had a lag of 11 secs. when the temp. of the source of heat was 700° , and of but 0.01 sec. when the temp. of the source was 1175° . The mixts. of CH_4 + air most readily ignited by a sustained source of heat were those contg. an excess of O, for not only do these mixts. require that the source of heat to ignite them shall be at a lower temp. but they need not be in contact so long with a source of heat at a temp. well above their ignition temps. The mixts. of other paraffin hydrocarbons (C_2H_6 to C_8H_{18}) most readily ignited by a similar source of heat contain an excess of the combustible gas. Judged by their relative ignition temps., mixts. of CH_4 + air are the most difficult to ignite while the others become easier to ignite as they ascend in the series $\text{C}_n\text{H}_{2n+2}$. A similar conclusion can be drawn from the lags on ignition at a given temp. Thus, a lower-limit CH_4 + air mixt. had to remain in contact with a surface heated to 700° for 9.8 secs. before it would ignite, while a lower-limit C_2H_6 + air mixt. in contact with the same surface at the same temp. ignited in less than $\frac{1}{2}$ sec.

Dyes. B. WYLAM, J. THOMAS and MORTON SUNDORF FABRICS, LTD. *Brit.* 235,247, Dec. 12, 1923. Anthraquinone vat dyes are reduced to their leuco compds. and caused to react with a chloroformic ester such as the Et or Ph ester or with phosgene. The products, when decomposed by alkali in the presence of a reducing agent, such as Na sulfide, yield vats which may be employed for dyeing and printing. Flavanthrone, anthraquinone-1,2,2',1'-hydroazine, dibenzanthrone, dimethoxydibenzanthrone and dichloroisodibenzanthrone are among the dyes which may be used.

Dyes. CHEMISCHE FABRIK GRIESHEIM-ILEKTRON. *Brit.* 235,169, June 7, 1924. Azo dyes are formed, either in substance or on the fiber, by coupling 2,3-hydroxynaphthoic β -naphthalide with an unsulfonated diazo compd. contg. in the 2- and 5- positions substituents at least one of which is halogen. The products are suitable for dyeing rubber as they are unaffected by the vulcanizing process. Among the starting materials which may be used are: 4-chloro-1,2 (or 1,3)-toluidine, 4-chloro-1,3 (or 1,2)-anisidine, 4-chloro-1,2 (or 1,3)-phenetidine, 2,5-dichloroaniline, 4-chloro-2-aminodiphenyl ether, and 4-chloro-2-aminophenyl benzyl ether.

Dyes. BRITISH DYESTUFFS CORPORATION, LTD. and H. H. HODGSON. *Brit.* 235,334, April 1, 1924. Aminothiophenol ethers are made by reducing *o,o'*-dithioaniline, in aq. or alc. soln., with Na sulfide and NaOH, or with Zn and HCl, and methylating or ethylating the *o*-aminothiophenol; or by similarly treating *p,p'*-dithioaniline, trithioaniline, 5,5'-dichloro-2,2'-dithioaniline, 4,4'- or 5,5'-dimethyl-2,2'-dithioaniline or 2,2'-dimethyl-4,4'-dithioaniline. The *o*-aminothiophenol ethers can be directly sulfonated but sulfonic acids of the *p*-aminothiophenol ethers are preferably prepd. by treating *p*-nitrochlorobenzenesulfonic acid with Na disulfide, reducing and alkylating. 5,5'-Dichloro-2,2'-dithioaniline is made by heating 2,5-dichloronitrobenzene with Na disulfide and oxidizing the aminochloromercaptan formed. 2,2'-Dimethyl-4,4'-dithioaniline is made by the action of Son *o*-toluidine and its hydrochloride. Monoazo dyes which dye wool in yellow to scarlet shades fast to milling are obtained by coupling diazo compds. of the unsulfonated aminothiophenol ethers with sulfonated azo dye components or by coupling the sulfonated diazo compds. with various specified usual dye components.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BÂLE and H. SCHOBEL. *Brit.* 234,956, April 16, 1924. Monoazo and diazo dyes are produced by coupling β -resorcylic acid with 1 or 2 mol. proportions of the same or different diazo compds. one at least of which is an *o*-hydroxydiazo compd. of the benzene series. When chrome-printed on cotton they produce fast yellow-brown, red-brown, violet-brown and similar shades. Among the starting materials which may be used are: 4-nitro-2-aminophenol, 4-chloro-2-aminophenol-5-sulfonic acid, 4-nitro-2-aminophenol-6-carboxylic acid and similar compds.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BÂLE. *Brit.* 235,862, June 17, 1924. Dyes giving yellow to orange to brown shades on animal fibers in an acid bath are obtained by treating with Cr formate, Cr fluoride, or other agent yielding Cr, the *o*-hydroxyazo dyes in which the second component is an acetoacetic acid deriv., e. g., "the dyes produced from 4-nitro-2-aminophenol or 4-chloro-2-aminophenol-6-carboxylic acid and Et acetoacetate. Various other examples are given.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BÂLE. *Brit.* 234,950, April 7, 1924. Azo-

triphenylmethane dyes which dye wool from an acid bath in yellow shades changed to fast green by after-chroming are prep'd. by diazotizing a comp'd. of the general formula $(R_2NC_6H_4)_2CHC_6H_4(SO_3H)NH_2$, in which R represents the same or different alkyl or aralkyl residues, and coupling with a 1-aryl-5-pyrazolone derived from an aminosalicic acid or a homolog or deriv. such as an aminocresotic acid. Triarylmethane derivs. of the general formula specified are obtained either by condensing 3-aminobenzene-sulfonic acid with the appropriate hydrol or by condensing 2-sulfo-4-nitrobenzaldehyde with a tertiary amine and reducing. 1-(2-hydroxy-3-carboxy-5-methylphenyl)-3-methyl-5-pyrazolone (used as one starting material for the dyes) is prep'd. from 2-hydroxy-3-amino-5-methylbenzoic acid, which is made by nitrating and reducing *p*-cresotic acid.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 235,877, June 21, 1924. Anils of 2,3-anthraquinonethioisatin or 2,3-anthracenethioisatin are prep'd. by condensing aromatic nitroso compds. with 2,3-anthraquinoneoxythionaphthene or 2,3-anthracenethionaphthene. Thioindigoid dyes are made by condensing these anils with the usual components such as indoxyls, thioindoxyls, acenaphthenones and the like. Numerous examples are given, producing dyes giving green, gray, heliotrope or lilac shades from a hyposulfite vat.

Dyes. CHEMISCHE FABRIK GRIESHEIM-HELEKTRON. Brit. 235,919, June 20, 1924. Pyrazoleanthrone and thiazoleanthrone dyes are halogenated, preferably by the action of Cl or Br in oleum or chlorosulfonic acid in the presence of I. Numerous examples are given.

Dyes. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 235,556, June 14, 1924. In prep'g. sulfureted dyes, the sulfurization is conducted in the presence of a Cu comp'd. which is not transformed into Cu sulfide during the reaction, to produce clearer shades. A yellow-green dye is formed from the leuco-indophenol obtained from 1-phenylaminonaphthalene-8-sulfonic acid and *p*-aminophenol by heating with Na sulfide, S and K cuprocyanide. A yellow-red dye is similarly obtained from 3-amino-6-hydroxydiphenazine.

Dyes. FÄRBERWERKE VORM. MEISTER, LUCIUS & BRUNING. Brit. 235,252, Jan. 28, 1924. Thioindigoid dyes are produced by heating a 2-anil of a 2,3-diketodihydro-1-thionaphthene with a hydroxynaphthothiophene, contg. only 1 thiophene nucleus or a nuclear substitution product. The products dye cotton, from the vat, red to blue-black shades. The products derived from hydroxy-2,3-naphthothiophenes may be halogenated, which increases their fastness and produces shades tending more toward violet. Numerous examples are given of producing the dyes and their intermediates.

Dyes. A. CARPMAEL and A. J. RANSFORD. Brit. 234,928, March 13, 1924. Hydroxythionaphthenes and thioindigo dyes are produced by treating with an acid condensing agent an *o*-substituted arylthioglycolic acid of the general formula $(1)XN-ARSCH_2COOY$ (2) in which Ar is a residue of a C_6H_4 or $C_{10}H_8$ ring, X is H_2 or H acyl or N:azo-component and Y is H or a metal (preferably a heavy metal). Examples are given of various dyes giving different shades of blue.

Dyes. A. CARPMAEL and A. J. RANSFORD. Brit. 234,962, April 22, 1924. Dichloro-*N*-dihydro-1,2,2',1'-dianthraquinoneazine is made by chlorinating the parent dihydroazine suspended in molten S at a temp. above the b. p. of SCl_2 and under ordinary pressure. I or $HgCl_2$ may be used as a catalyst and a temp. of 210–220° is suitable. The product is boiled with Na sulfide to remove S and reduce the green-colored azine to the hydroazine. It dyes cotton from the vat (even in hard H_2O) bright greenish blue shades fast to Cl.

Halogenated thionaphthisatins and dyes produced from them. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 236,332, May 8, 1924. Thionaphthisatins are treated with halogen in an inert diluent; e. g., monobromo derivs. of 1,2-, 2,1- and 2,3-thionaphthisatins may be formed by brominating in $PhNO_2$. Thioindigoid dyes dyeing cotton from the vat in Bordeaux-red, brown, violet and other tints are obtained by condensing the halogenated thionaphthisatins with hydroxythionaphthene, hydroxythionaphthencarboxylic acid, acenaphthenone or various compds. contg. a reactive cyclo methylene group.

Dyeing. A. J. ESCAICH and J. P. WORMS. Brit. 236,131, Dec. 22, 1923. Animal or vegetable fibers are dyed by treatment with metal salts or oxides, e. g., Cu or Co sulfates, in the presence of diaminophenol, dinitroresorcinol or diaminoresorcinol. Red-brown and reddish yellow dyeings are produced.

Dyeing cellulose acetates. R. CLEVEL. U. S. 1,571,320, Feb. 2. Artificial silk, films or other forms of cellulose acetates are treated, for production of development dyes on them, with 2 of the 3 dye-forming factors: base, diazotizing material and de-

veloper, in one bath, and with the third factor in another bath. A protective colloid is used in at least one of the baths.

Dyeing cellulose acetate. BRITISH DYESTUFFS CORPORATION, LTD., J. BADDILEY and J. HILL. Brit. 236,037, June 20, 1924. "Acetyl silk" is dyed with monoazo dyes from aniline or its homologs or derivs., *e. g.*, halogenated aniline, toluidine or 1,3-dihydroxyquinoline. The dyes may be used in aq. suspension or in colloidal form with a dispersing agent.

Dyeing cellulosic fibers. TEXTILWERK HORN AKT.-GES. Brit. 236,558, July 3, 1924. The process of Brit. 195,619 (*C. A.* 17, 3613) for treating cellulosic fibers with aromatic sulfonyl chlorides is applied to the treatment of vegetable fibers dyed with direct colors to render them immune from cross-dyeing with direct colors. The fibers obtained may be dyed with acid, basic or acid mordant colors.

Dyeing jute, etc. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 236,525, July 4, 1924. In dyeing jute, coconut fiber and similar materials with basic dyes there is added to the dye bath or to the wetting bath sulfite cellulose liquor or its active constituents or conversion products.

Dyeing wool. C. S. BEDFORD. Brit. 236,388, July 19, 1924. Wool is mordanted in a boiling bath of Na or K dichromate, glycerol, glucose, invert sugar, starch, dextrin, urine, tanning substances or their mixts. as reducing agents and HOAc, HCOOH, HCl, H₂SO₄ or lactic acid in slight excess. Examples are given of dyeing processes with different dyes.

Dye vat. F. M. MORTON and G. W. MORTON. U. S. 1,571,864, Feb. 2.

Dyeing hair, etc. R. L. EVANS. Brit. 234,971, May 5, 1924. In dyeing hair, fur, feathers and the like, a compd. of an aromatic amine and an aldehyde or ketone is oxidized, *e. g.*, with H₂O₂. A compd. prepd. by mixing *p*-phenylenediamine and acetone-Na-bisulfite may be used.

Artificial silk. FÄRBFABRIKEN VORM. F. BAYER & Co. Brit. 235,850, June 18, 1924. To prevent formation of air bubbles in the pptn. bath, the app. in contact with the bath may be preliminarily boiled in H₂O to free it from air.

Spinning artificial silk. O. KOHORN & Co. and A. LEHNER. Brit. 235,527, June 12, 1924. Mech. features.

Apparatus for making artificial silk by the stretch-spinning process. J. BALTHASAR and A. VIOLA. Brit. 235,852, June 21, 1924.

Cleaning spinning funnels for artificial-silk manufacture. J. P. BEMBERG AKT.-GES. Brit. 235,853, June 18, 1924. Mech. features.

Apparatus for spinning artificial-silk filaments. M. HÖLKEN. Brit. 236,211, June 24, 1924.

Apparatus for making filaments of artificial silk by the dry-spinning method. SOC. CHIMIQUE DES USINES DU RHÔNE. Brit. 236,393, Jan. 10, 1924.

Spinning threads from cellulosic ester or ether solutions or similar viscous liquids. N. B. GRILLET. U. S. 1,571,474, Feb. 2. Mech. features.

Retting flax. G. AUSTERWEIL and L. PEUFAILLIT. Brit. 236,590, July 7, 1924. In retting flax, hemp or similar materials the material is heated in an autoclave under pressure for several hrs. in H₂O contg. a small proportion of an "alc. of high mol. wt.," *e. g.*, cyclohexanol, methylcyclohexanol, terpineol and alcs. such as benzyl alc. A small quantity of soap may be added near the end of the treatment.

Cutting and dressing wool. SEVERN MILLS Co. Brit. 236,428, Oct. 20, 1924. Wool which when spun and woven closely resembles the product from short merino type wool is obtained by cutting up long-fiber wool contg. grease, suint, etc., intermixing, washing and drying the fibers. An app. is described.

Moth-proofing fabrics. LARVEX CORPORATION. Brit. 235,914, June 21, 1924. A neutral soln. contg. fluosilicate of Na, K, Li, Zn or Al is used, with or without fluorides, alkali benzenesulfonates, naphthalenesulfonates or sulfates of alkali metals, Zn or Al. Brit. 235,915 specifies similar solns. also contg. an org. acid, *e. g.*, oxalic, tartaric, formic or HOAc.

Moth-proofing woolen fabrics, etc. LARVEX CORPORATION. Brit. 236,218, June

24, 1924. NaF, Na oleate, gelatin and citric acid may be used together and other org. colloids may be used to facilitate wetting and impregnation of the material under treatment.

The settling of paint pigments. ANON. *Farbe und Lack* 1925, 603-4.—A brief review of the causes of pigment settling in ready mixed paints; of its prevention by the addn. of various aq. alk. solns., of colloidal solns. of heavy metals in drying oils, of heavy metal soaps of fatty acids, etc. F. A. WERTZ

The settling and packing of mixed paints. WM. C. ARSEM. *Ind. Eng. Chem.* 18, 157-60(1926).—In a mixed paint the pigment grains are to some extent deflocculated and dispersed by the free acids in the vehicle, and the metallic soaps are maintained in the sol condition by the same agency. If no chemical changes take place in this system, the pigment grains may settle through the action of gravity, but will not adhere, and soft settling will result. In a stored paint slow chemical reaction between basic pigments and free acids forms basic soaps with little dispersing power. Some of the soap will be pptd. as a result of this loss of free acid from the vehicle, and the pigment grains which are thus freed from adsorbed dispersing agent tend to adhere to each other by virtue of the free surface valencies. When the removal of dispersing agent occurs after gravity has done its work in bringing the particles close together, they will adhere more or less strongly to each other and hard settling will be the result. F. A. WERTZ

The determination of volatile solvents in paints, varnishes, etc. HANS WOLFF. *Farben-Ztg.* 31, 746-7(1925).—A convenient receiver for detg. the volatile solvents in paint products by the steam-distn. method has a small side tube connected to it near the bottom in such a way as to allow the condensed H₂O to overflow. A receiver of very small diam. is useful to det. when all the solvent has been recovered. The solvent in certain basic paints of heavy consistency is carried over by the steam very slowly; the addn. of a small quantity of mineral acids to such paints will speed up the distn. Illus. F. A. WERTZ

The catalytic effect of lead and manganese on the drying of China wood oil. G. F. LUDWIG. *Ind. Eng. Chem.* 17, 1160-1(1925).—In a "25 gal." rosin-wood varnish, 0.26% Pb, or 0.03% Mn is the most efficient amt. of these metals when used alone, to secure the max. drying rate. The metals in the form of PbO and of Mn borate, resp., were incorporated hot into the varnish base. Drying-time curves for varying concns. of metal are given. F. A. WERTZ

An exposure test of water-line paints. E. F. FIGG. *J. Oil Colour Chemists' Assoc.* 8, 314-34(1925).—Steel plates were primed over half their surface with various priming paints, and the whole surfaces of the panels then given a coat of boot-topping paints of various compns. These were exposed from a pier at the water line and inspected after 18 weeks and 56 weeks exposure. Compn. of the paints and application and inspection data are tabulated, with photographs. A priming coat of red lead in raw linseed oil with a finishing coat of white lead in linseed oil tinted with lampblack and two coats of ZnO and Zn dust in raw linseed oil gave good protection. The rust inhibition expected from basic Pb chromate in raw linseed oil was not confirmed; better protection was obtained with iron oxide-raw oil paints. The use of varnishes, in general, decreased the durability of the paints. In one case the anomalous result was obtained of one coat of paint affording better protection than two coats. The bituminous paints in the test did not show up well. Only one of six com. paints specially intended for water-line protection included in the tests gave satisfactory results; this consisted

of ZnO in a slightly thickened linseed oil. It appears that the most important characteristic to be sought in a boot-topping paint is permanent elasticity. F. A. WERTZ

Important questions in the milling of dry colors. P. W. RICHTER. *Farben-Ztg.* 31, 748-50(1925).—A discussion of production problems, maintenance of mills, etc. F. A. WERTZ

Cadmium and cadmium yellow. FREITAG. *Farbe und Lack* 1925, 606.—A review of Cd production statistics and the resultant effect on the price and com. availability of the metal and of Cd yellow, with a review of recent patents for producing Cd pigments. F. A. WERTZ

Preparation of metal surfaces for painting and lacquering. W. J. MISKELLA. *Paint, Oil and Chem. Rev.* 80, No. 27, 10-1(1925).—The importance of thorough cleaning of surfaces to be painted and especially lacquered is emphasized; the removal of slushing compds. and the general cleaning of sheet metal are discussed. F. A. W.

Experiments on accelerated testing of rust-preventive paints. HANS WOLFF. *Korrosion und Metallschutz.* 1925, 85, 130; *Farben-Ztg.* 31, 706; cf. C. A. 19, 2418.—For accelerated testing, painted panels are placed in a glass cylinder through which air of various relative humidities, and temps., or contg. various amts. of corrosive gases, is circulated. The results are compared with those obtained on outdoor exposure. A certain cycle of the accelerated tests, e. g., produced the same loss in elasticity of an 80% white lead-20% barytes paint in 75 to 100 days, as was caused by 18 months' outdoor exposure. Exposure of a film shortly after drying, to strong sunlight or ultra-violet rays, is conducive to cracking; this is perhaps due to the action of the ultra-violet rays in altering the dispersion of the colloidal system of the film. High humidity has less effect on the drying of a white lead paint than on a ZnO paint. F. A. WERTZ

Rust-preventive paints from an electrolytic standpoint. H. LIEBREICH. *Farbe und Lack* 1925, 602.—That the use of an alk. salt in the priming coat of paint on metal, followed by two coats of a durable paint, gives better protection against rust than if the alk. salt is not present to inhibit electrolytic corrosion, has been shown by practical experience. The finishing coats prevent the H₂O-sol. alk. salt from washing out of the film. If ordinary paint coats were actually impermeable to H₂O, they would effectually prevent rusting. The manner in which moisture penetrates paint films by imbibition is discussed. F. A. WERTZ

Rust-preventive materials. JULIUS SWOBODA. *Chem.-Ztg.* 49, 977-9, 994-7 (1925).—A review of the theories of corrosion of iron, of metallic coatings, lacquer, asphaltic preps., portland cement, heavy mineral oils and greases, metallic soaps, paints, etc., used as rust preventives. F. A. WERTZ

Nitrocellulose lacquers. B. SCHEFFLE. *Farben-Ztg.* 31, 865(1926).—A very brief review. The dried lacquer film is not identical in structure with the original nitrocellulose; in the process of gel or film formation from the liquid lacquer certain polymerization and aggregation of mol. particles take place. The gloss of a film is influenced greatly by the type of solvent present. F. A. WERTZ

Accelerated weathering as applied to lacquer enamels. H. A. NELSON. *Can. Chem. Met.* 10, 11-3(1926).—Relative gloss retention, chalking tendencies, and susceptibility to cracking of paint films heretofore have been detd. by accelerated tests, but certain typical failures such as fine hair-line checking have not been reproduced. This deficiency has been largely overcome by increasing the O content of the air in the light-exposure chamber and by adding periodic exposure to humid air contg. SO₂ and CO₂. The increased O content has doubled the general deteriorating effectiveness of the test, has increased chalking and reproduced hair-line cracks. SO₂ and CO₂ have practically no effect in the presence of light, but produce H₂O-sol. products within the film, in the dark with high humidity. The relative ratings of a series of nitrocellulose lacquers after exposure to the accelerating cycle agree reasonably well with the outdoor exposure ratings. Pigmented enamels made with the cottons of higher viscosity showed greater durability and greater tensile strength and distensibility than those made with 0.5 sec. cotton. This may be due to the longer fibers used in the production of the cottons of higher viscosity, or to the freedom from suspended matter which usually is present in the 0.5 sec. cotton solns. Greatest durability resulted from a ternary mixt. contg. 50% of 0.5 sec. cotton, 24% of 4 sec. cotton, and 26% of leather dope. The last by itself showed the poorest durability of all the cottons tested. In weathering, light colored enamels contg. 19.5% of 0.5 sec. cotton yellowed more than those contg. 16% of the same cotton; the former contg. pigments transparent to ultra-violet light, were more durable than the latter, but with pigments opaque to ultra-violet light, the enamels contg. the lower cotton content were more durable. Increasing the gum content from 1.5% to 3% decreased durability and increased gloss when damar gum was

used, but with ester gum both these properties were increased. Comparative tests of tricresyl phosphate and triphenyl phosphate as plasticizers showed little preference except when the tests were run at 48°, when the films contg. the latter rapidly became weak and brittle apparently through crystn. of the triphenyl phosphate (C. A. 15, 2003). The addn. of clear lacquer to a pigmented lacquer in the finishing coat, or a finishing coat of clear lacquer or of varnish, always decreased the durability of the pigmented lacquer job. A wax finish stands up better than a buffed finish. Results and lacquer compns. are tabulated.

F. A. WERTZ

The determination of the color depth of varnishes, oils, etc. FELIX WILBORN. *Farben-Ztg.* 31, 747 (1925).—I-KI solns. are preferred as color standards, and the color comparisons may be made in a colorimeter with secondary standards of greater permanency if desirable. Comparisons must be made with a layer of oil and of standard soln. of equal thickness, the method suggested by Fonrobert (C. A. 20, 117). Comparing layers of different thicknesses gives incorrect results.

F. A. WERTZ

The standardization of driers. P. MÜLLER. *Farben-Ztg.* 31, 696-8 (1925).—A further discussion of the factors involved in the standardization of drier (cf. C. A. 20, 299).

F. A. WERTZ

Comparative examinations of various types of shellac. A. TSCHIRCH AND H. H. SCHÄFER. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 309-14 (1925).—Some 30 different types and grades of shellac, obtained from the Indian Inst. of Science in Bangalore, were analyzed for H₂O, H₂O ext. (sugar, albumin and H₂O-sol. salts), total wax, wax sol. in hot alc., wax insol. in hot alc., H₂O-sol. coloring matter, total resin, ether-sol and ether-insol. resin and residuc. The analytical methods are given in detail and results are tabulated. The following conclusions are arrived at: (1) Shellac from male insects contains a larger amt. of H₂O-sol. substance, H₂O-sol. color and residuc, but contains less wax and resin. (2) Shellac from female insects contains less sugar and ether-sol. resin but more wax and total resin. (3) All Siam shellacs contain much sugar. (4) There is a definite relation between sugar and H₂O content. (5) *Acacia catechu* shellac furnishes less laccic acid. (6) *Zizyphus xulophyus* shellac shows a high H₂O and sugar content but little laccic acid and resin. (7) A shellac from Java, the wax of which consists of about equal parts of alc.-sol. and alc.-insol. wax, behaves quite differently from Indian shellac.

P. ESCHER

Linoleum and triolin. A. SIMON. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 272-5, 308 (1925).—A comparison of the mech. and chem. properties of linoleum with those of triolin as floor-coverings gave the following results. Mech.: Linoleum, a mixt. of linoxyn, rosin and cork-powder, permits sliding of leather over its surface about 10% less readily than triolin which is a mixt. of gelatinized nitrocellulose with cork, sawdust, etc., and its tensile strength is slightly greater than that of triolin. Elasticity was detd. by measuring the depth to which a weighted plate sinks into the sample and noting the time of recovery to normalcy: if the linoleum recovery is called 100%, that of triolin is only 60%. Abrasion of linoleum is 20% less than that of triolin. Chem.: Triolin is sensitive toward acids while linoleum is sensitive toward alkalies. Steam of 130-135° left linoleum unchanged but blistered and decomposed triolin to a brittle mass. A Bunsen flame charred linoleum only superficially but triolin caught fire and spread decompn. beyond the flame area with formation of smoke and gas. Radiant heat confirmed the findings with regard to gas (at 57°) and smoke-formation (at 115°). Examn. of the gases showed the presence of 8.3-9.7 g. HCN per 1 g. of triolin, and analysis of the gas after removal of HCN showed 33.0% CO₂, 32.2% CO, 26.7% NO and 8.1% N₂. White mice died in a gas-air mixt. from triolin after a little more than 1 min.

P. ESCHER

Rustproofing of materials (McDONNELL) 9.

FALLOON, DALTON BOYLES: **Zinc Oxide; History, Manufacture and Properties as a Pigment.** New York: D. Van Nostrand Co. 145 pp. \$1.75. Reviewed in *Ind. Eng. Chem.* 18, 326 (1926).

MILLAR, ANDREW: **Scumbling and Colour Glazing.** 2nd ed. London: Trade Papers Pub. Co., Ltd. Reviewed in *J. Oil and Colour Chemists' Assoc.* 8, 305-6 (1925).

TOCH, MAXIMILLAN: **The Chemistry and Technology of Paints.** 3rd ed. revised and enlarged. New York: D. Van Nostrand Co. 413 pp. \$5.

Filling and priming composition for use with paints, etc. DEUTSCHE FORSCHUNGS-UND VERSUCHS-ANSTALT GES. Brit. 235,133, June 3, 1924. Al(OH)₃ is mixed with linseed oil, with or without Fe(OH)₃ or with oil paint or varnish.

Composition for removing paint. O. L. FLURGEL. U. S. 1,570,957, Jan. 26. KOH 1 lb., Na_3PO_4 $\frac{1}{2}$ lb., oxalic acid $\frac{1}{2}$ lb., $\text{Ca}(\text{OH})_2$ 1 lb., starch 3 oz. and H_2O about 1 gal.

Linoleum. LOBOSITZER AKT.-GES. ZUR ERZEUGUNG VEGETABILISCHER ÖLE AND G. DUBSKY. Brit. 235,590, June 16, 1924. Linseed oil or other drying oil is thickened by injecting air or heating (suitably with addn. of Pb resinate) and may be mixed with resin, ocher and cork or other usual fillers.

Nitrocellulose varnishes. ATLAS POWDER CO. Brit. 236,190, June 24, 1924. In dissolving nitrocellulose or mixts. of nitrocellulose and glycerol-resin-ester, "ethyl glycol," $\text{OH}:\text{CH}_2\text{CH}_2\text{OC}_2\text{H}_5$, is used as solvent, with or without non-solvent diluents such as C_6H_6 , toluene, xylene, gasoline and Et, Pr, Bu and Am alcs. Camphor, tricresyl phosphate and other modifying ingredients or pigments may be added.

Metallic gloss coating. DEUTSCHE FORSCHUNGS- UND VERSUCHS-ANSTALT GES. Brit. 235,134, June 3, 1924. A mixt. of Pb ore such as galena and varnish, lacquer, siccate or rubber soln. is used for coating and after drying is rubbed or burnished, preferably with a wire brush. Pigments may be added to the coating compn.

Composition for treating rail fabrics of pool tables. E. HAMBLIN, JR. U. S. 1,570,740, Jan. 26. $86\frac{2}{3}\%$ of a mixt. of varnish resin, Al resinate and thinner is mixed with $13\frac{1}{3}\%$ of another mixt. formed of glue, shellac and "banana oil" and this compn. is applied to rail fabric of pool tables or the like to render it more durable.

Synthetic resins. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 235,589, June 13, 1924. In order to produce a resin capable of being hardened by a short heating, the hardening of complex ester resins such as those formed from glycerol and phthalic anhydride or phthalic acid is interrupted when the resin is just short of the intermediate stage of condensation. The interruption may be effected by heating the fusible resin to $210\text{--}290^\circ$ in solvents such as diethyl phthalate or benzyl benzoate and a soln. such as formed with diethyl phthalate may be poured into C_6H_6 to ppt. the resin.

Synthetic resins. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 236,591, July 5, 1924. The hardening of synthetic resins such as those produced from glycerol and phthalic acid or anhydride is accelerated by admixing with the initial resin a "dehydration catalyst," *e. g.*, CaO , MgO , ZnO or finely divided metals such as Zn or Fe obtained from their oxides by reduction with H. Fillers, *e. g.*, marble dust, and solvents, *e. g.*, acetone, may be used in mixts. contg. the hardening agent.

Coloring synthetic resins, etc. QUAKER OATS CO. Brit. 234,862, Jan. 7, 1924. Materials such as S-phenol resins, phenol-formaldehyde resins, wood, lacquers, enamels, veneers, varnishes, "plastic compositions," shellac, rosin or asphalts (which are not already sufficiently black) are colored black by use of furfural and HCl or other acid, with or without heating. A small quantity of aniline oil may be added to facilitate coloring without undue heating. In making products such as those from PhOH and S chloride, the coloring may take place simultaneously with the reaction by which the material is formed or may be effected subsequently.

Resinous compositions. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 235,595, June 13, 1924. Complex ester resins such as those produced from glycerol and phthalic acid or phthalic anhydride are blended with China wood oil, linseed oil, soy bean oil, cottonseed oil, castor oil or other drying, semi-drying or non-drying oils and heated to make varnish or japan compns. in the presence of a non-volatile solvent such as benzyl benzoate, benzyl acetate, PhNO_2 , toluidine, benzyl alc, cresol, aniline, glycol diacetate, phenylhydrazine or *o*-cresyl benzoate. The resin oil blend may be freed from the solvent initially used and subsequently dissolved in a volatile solvent such as solvent naphtha.

Furfural resin composition for molded articles. T. S. HUXHAM. U. S. 1,571,447, Feb. 2. Furfural resin or similar material which has a tendency to stickiness during hot molding is mixed with a small proportion of a metallic soap, insol. in H_2O , *e. g.*, Zn stearate or Al palmitate.

Washing kauri gum and the like. S. P. EVANS. Brit. 235,079, Nov. 4, 1924. Kauri gum or similar material is sepd. from foreign substances by agitation with an aq. soln. (preferably a salt soln.) of such d. as to float the gum. An app. is described.

Ink. A. ROGERS AND MIMO CORPORATION. Brit. 235,922, Dec. 27, 1923. Sympathetic ink for printing on newspapers, etc., comprises alc., a thickening agent such as glycerol and a sensitive ingredient, *e. g.*, phenolphthalein, Co chloride, FeSO_4 , FeNH_4 sulfate or sugar. CCl_4 may be added and a mixt. of resin and soap may be used with phenolphthalein and sugar.

Printing ink. J. H. CAUGHLAN. Brit. 236,329, May 5, 1924. Air-blown asphalt is mixed with C black, Pb linoleate and a binder formed of liquid asphalt and petroleum oil of thick creamy consistency.

Printing patterns for garments, etc. H. COLLINS. Brit. 235,968, Dec. 28, 1923. Patterns for garments may extend uninterruptedly over several pages of a newspaper and are printed with sympathetic ink, *e. g.*, an ink formed with phenolphthalein, glycerol, alc. and CCl_4 which may be subsequently developed with a soln. of Na_2CO_3 or other alkali.

Ink remover. H. W. BECKER. U. S. 1,571,313, Feb. 2. Formic acid 21, glycerol 3, ethyl ether 1, bay oil 0.1 and cologne 0.05 part.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Oils and fats industries during 1925. REX FURNESS. *Ind. Chemist* 2, 17-8 (1926). E. H.

The oleic acid content of fatty acids in the foots of palm-kernel, babassu and licury oil. F. WITTKA. *Z. deut. Oel-Fett-Ind.* 45, 417-8(1925).—The frequent observation that the foots acids of palm-kernel, babassu and licury oil have a much higher I no. than their normal oils, indicating a high % of oleic acid finds an explanation in the insufficient removal of the brown rind from the nut meat. This rind carries an oil of I no. 37.5, 55.7 and 36.0, resp., for the 3 oils and their high lipase contents cause a ready decompn. The same facts have been observed for coconut oil. P. ESCHER

The action of phenylhydrazine and hydrazine on fats and fatty acids. J. VAN ALPHEN. *Rec. trav. chim.* 44, 1064-70(1925). (In English).—van A. (*C. A.* 19, 1235) obtained various phenylhydrazides of acids by the action of ketenes on PhNHNH_2 and has now prepd these compds. by the action of anhydrous PhNHNH_2 on the esters of fatty acids and especially the glycerol esters or fats. The expts. of Falcicola (*C. A.* 9, 866; 14, 3066), who split fats with NH_2NH_2 in aq. soln., and so obtained the hydrazides of the fatty acids while unsatd. fatty acids (among others oleic acid) were converted by the reducing action of the hydrazine into satd. fatty acids (stearic acid), were repeated with abs. MeOH solns. of NH_2NH_2 . By this means also fats are easily ruptured with the formation of the hydrazides of fatty acids. As in aq. soln. (cf. F.) the unsatd. acids are hydrogenated by the NH_2NH_2 and oleic, elaidic and the unsatd. acids of linseed oil are hydrogenated to stearic acid and give stearic acid hydrazide. The fatty acids can be recovered by sapon. the hydrazides with dil. H_2SO_4 and BzH , which fixes the NH_2NH_2 . Fatty acids and fats give the corresponding phenylhydrazides of the fatty acids by heating to 130-50° with PhNHNH_2 . Unsatd. acids such as oleic acid and hydroxy acids such as ricinoleic acid are not reduced in this way to satd. acids by PhNHNH_2 but give the phenylhydrazides of the above mentioned acids. The previously unknown *phenylhydrazides of palmitic and ricinoleic acids* (m. 110.5° and 63°, resp.) were prepd. by this method. E. J. W.

Autoclave fat splitting and apparatus for it. H. RIEMER. *Z. deut. Oel-Fett-Ind.* 45, 653-5, 701-3, 720-2, 737-9(1925), illus.—The essential conditions of intimate emulsion, high temp. and pressure are discussed and the various processes of fat splitting are considered under the following captions, giving full details of operation: (1) Splitting under pressure (autoclaves). (2) In open vessels (Kreibitz process). (3) By H_2SO_4 . (4) By contact substances (Twitchell process). (5) By fermentation. Autoclaving by means of bases. Splitting with H_2O alone at high pressure. Riemer's process (Austrian patent 101,041). P. ESCHER

Qualitative test for unsaponifiable matter in fish oil. D. HOLDE AND A. GORGAS. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 314-6(1925).—Some fish oils with a high content of unsapon. matter show no turbidity when tested qual. by sapon. and diln. with H_2O . An investigation of this abnormal behavior revealed the fact that the turbidity appears only when the H_2O is added dropwise to the soap soln. instead of at once, in which latter case the unsapon. matter coalesces into transparent oil globules which may escape detection. It appears that unsatd. hydrocarbons, characteristic of fish oils, present this absence of turbidity more easily than the satd. hydrocarbons, characteristic of many mineral oils. P. ESCHER

The manufacture and properties of sulfonated fish oil and sulfonated neatsfoot oil. E. STIASNY AND C. RIESS. *J. Am. Leather Chem. Assoc.* 21, 76-108(1926).—See *C. A.* 20, 302. J. A. WILSON

The deodorization of oils and fish oils. J. H. MILLER. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 283-4(1925).—A brief survey of the present practice in deodorizing edible and industrial oils. P. ESCHER

Some experiments on applying physicochemical method to the investigation of Manchurian bean oil. N. I. MOROSOV. *J. Trans. Russian Chinese Polytech. Inst. Harbin*, No. 4, 121-33(1925).—The methods for the detection of Manchurian bean oil added as an adulterant to other vegetable oils is discussed. The properties of the bean oil approximate closely those of maize oil and sunflower oil. Detection of the presence of bean oil in adulteration of these oils is difficult especially when present in small quantities. Color reactions, such as those of Settimi and Newhall, have been proposed but are not always of value. The property of several vegetable oils to produce emulsions under described conditions was investigated. Five cc. of an oil is mixed with 2 cc. of CHCl_3 and then 3 cc. of a 5% soln. of Cu sulfate or Co nitrate is added. When the mixt. is shaken well for 1 min., an emulsion is produced the stability of which depends upon the kind of oil. Bean, sunflower, crude hempseed, peanut and cedar oils have been thus investigated. Bean oil gives a very stable emulsion, while the others very soon divide into 2 immiscible layers. With some specimens of bean oil a flocculent ppt. is formed. Mixts. of crude hempseed oil with 10, 20, 30, 40 and 50% of crude bean oil have been prepd. and treated as above. The presence of the bean oil may be detected by the flocculent ppt. formed on the interface between 2 layers while pure hempseed oil produces either a very slight or no ppt. By this method 10% of bean oil added to hempseed oil is easily detected. NATHAN VAN PATTEN

The Idrapid reagent. SCHRAUTH. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 271(1925).—Polemical. Cf. *C. A.* 19, 1786, 3608. P. ESCHER

Rancidity and yellowing of soap. C. DE BELSUNCE. *Bull. mat. grasses inst. colonial Marseille* 1925, 191-2.—Pressing of soap in dies accelerates rancidity. The use of very pure fats in soap is a cause of rancidity. At the time when the Leblanc soda was used, rancidity of soap was rare. Soaps contg. resin do not become rancid. Resinous perfumes prevent or mask rancidity and prevent yellowing. Filled soaps grow rancid less easily than the unfilled. Dry and powdered soaps easily become rancid. The following lab. expts. were made. Soap boiled with the addition of 1% of $\text{Na}_2\text{S}_2\text{O}_3$ and pressed in a die remained white and odorless for 6 mos. and soap made without this addition became rancid and yellow in 1 mo. Unpressed soap contg. 1% NH_4HCO_3 did not discolor nor become rancid in 4 mos., nor did soap contg. 1% NaHCO_3 . Unpressed soap contg. 1% Na_2CO_3 , $(\text{NH}_4)_2\text{CO}_3$, and 1% $\text{Na}_2\text{S}_2\text{O}_3$ remained white and odorless 4 mos. The use of 1% $\text{Na}_2\text{S}_2\text{O}_3$ and resin is recommended. E. SCHERUBEL

The utilization of dirty fats and oils for curd soaps. A. LARSEN. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 319-20(1925).—Detailed directions are given for sapon. dirty oils separately from coconut or palm-kernel oil and removing the dirt by a strong lye change followed by a salt change and bleaching operation and finally sapon. with coconut or palm-kernel oil. P. ESCHER

Soap bleaching with persulfates. E. SCHOTTE. *Soap* 1, 19-20(1926).—Remarks on methods and results as described in foreign journals. E. SCHERUBEL

Soap powder without milling. R. SIEBEL. *Z. deut. Oel-Fett-Ind.* 45, 739-41(1925).—S. describes several types of app. for making soap powder in which the hot saponified soap is mixed in an agitator kettle with the desired ingredients (soda ash and silicate) and by blowing cold air through the solidifying mass a light, fluffy powder is obtained which is floor-cooled and then packed; a simple grinding machine may be introduced prior to packing. P. ESCHER

Hydrogen for hydrogenation of oils (KNOWLES) 18. Resolving emulsions (U. S. pat. 1,570,987) 13. Fractionating tower for distillation of oil (U. S. pat. 1,571,805) 1.

Purifying oil. A. W. LIMPSON. Brit. 234,886, Feb. 29, 1924. Oil is subjected to intimate contact with hot H_2O and then to centrifuging. An app. is described.

Column still for purifying oils and fats. H. BOLLMANN. Brit. 235,514, June 12, 1924. In removing odorous substances from oils and fats, as described in Brit. 218,910 (C. A. 19, 583), the oil passes downwards through a column contg. chambers filled with Raschig rings or similar packing against a current of steam.

Extracting oil from cold whale blubber, etc. F. KRUPP GRUSONWERK AKT.-GES. Brit. 235,550, June 10, 1924. Mech. features.

Detergents. H. C. WILSON. Brit. 235,265, March 3, 1924. An alk. soln. such as an aq. Na_2CO_3 soln. is mixed with a soln. of oleic acid or other fatty acid in trichloroethylene or other chlorohydrocarbon deriv., with or without addn. of alc., phenols or other substances.

Detergent. G. ZIMMERLI CHEMISCH-TECHNISCHE FABRIK. Brit. 236,209, June 27, 1924. A cleansing and degreasing compn. is prepd. by mixing sulfonated castor oil or similar material with a hydrogenated phenol, e. g., methylcyclohexanol prepd. from crude cresol, with or without addn. of K-olein soap or the like.

Detergent. C. T. WIESE. U. S. 1,571,829, Feb. 2. A mixt. adapted for cleaning dyed fabrics is formed from a dehydrated soap base obtained from 19 lbs. sapond. cottonseed oil mixed with $2\frac{1}{2}$ gals. H_2O , a soln. formed from 1 lb. sassafras and 8 oz. soap with $2\frac{1}{2}$ gals. H_2O , fuller's earth, Na hyposulfite, Na salicylate, borax and additional H_2O .

Flaked soap. G. F. DAWES. U. S. 1,571,625, Feb. 2. Soap contg. a large proportion of H_2O is subjected to a "dry heat" at a temp. of 120–205° and at atm. pressure to expel the H_2O and form a porous mass.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Returning condensate from one body to another. F. STAUDINGLER. *Sucre. belge* 44, 505–10(1925).—The suggestion was repeatedly made that part of the heat contained in the water condensed in the heating space of an evaporator might be recovered by allowing the water to flow from one body to another. S. gives 2 calcs. One is of a quadruple effect in which the water condensed in a pre-evaporator is used as boiler-feed and the surplus is passed to the first body; the water from the first body goes to the second body. The other calcn. relates to a quadruple effect in which the system of return is not used. The calcs. prove that the radiation losses are such as to make any appearance of economy illusory. The saving does not compensate the cost of installation, and the complications introduced into the system. T. MARKOVITS

The Elliot filtration apparatus. A. A. BLOWSKY. *Facts about Sugar* 20, 758–9 (1925).—An invention for detg. the relative filterability of raw sugars for plant control and its method of use. T. MARKOVITS

Non-condensing electric generators. J. H. GRAINER. *Facts about Sugar* 20, 976–8(1925).—The relative advantages are given for sugar mill service of the different types of prime movers. T. MARKOVITS

The cane sugar industry in Peru. G. KLINGE. *Facts about Sugar* 20, 1096–7 (1925).—The operations are carried on all year under unique climatic conditions. K. gives the organization and methods of cultivation. T. MARKOVITS

Invertase process in cane sirup manufacture. H. S. PAINE AND C. F. WALTON. *Facts about Sugar* 20, 1024–6(1925).—The treatment of cane sugar sirup with invertase is the most satisfactory method for preventing crystn. The use of invertase in sirup manuf. and the method of employment are described. T. MARKOVITS

Clarification in the cane sugar factory. W. E. SMITH. *Facts about Sugar* 20, 1138–47(1925).—Clarification of cane juice is seen on analysis to consist of 4 main phys. or chem. reactions: (1) flocculation of colloids by change of H-ion concn.; (2) flocculation of those colloids which are coagulated by heat; (3) formation of insol. lime salts; (4) formation of sol. lime salts and chem. reaction products. The paper goes very much in detail in regard to the theory of clarification and the importance of liming control and the disposal of the filterpress juice. T. MARKOVITS

Composition and food value of cane sirup. H. S. PAINE. *Facts about Sugar* 20, 998–9(1925).—P. considers the color of a sirup more or less as an index of quality and distinguishes between the Georgia and Louisiana types of sirup. It is pointed out that the sugar content of sirup is the basis of its food value and that the ash and the org. non-sugars have some incidental food value. T. MARKOVITS

The root rot problem of sugar cane. W. T. MCGEORGE. *Facts about Sugar* 20, 730-2(1925).—Studies in toxic conditions and causes. The relation of potash to disease resistance is described. T. MARKOVITS

Progress of beet-sugar manufacture in 1925. F. O. VON LIPPIMANN. *Chem.-Ztg.* 50, 61-4(1926); cf. *C. A.* 19, 1063. E. H

Possibility of cultivating sugar beet in Morocco. ANON. *Bull. soc. encour.* 137, 745-89(1925).—A discussion of the problem from the biological, technical, economic and com. standpoints. A. PAPINEAU-COUTURE

The beet sugar industry in Western Canada. J. W. EVANS. *Facts about Sugar* 20, 725(1925).—Establishment of beet culture in southern Canada promises to be the nucleus of great development. T. MARKOVITS

Subjecting of molasses treated with zeolites to the Steffens process. F. R. BACHLER. *Ind. Eng. Chem.* 18, 180-2(1926).—Previous literature is reviewed. Lab. expts. point to the conclusion that zeolite-treated beet molasses subjected to the Steffens process may be expected to yield a higher recovery of sugar and saccharate of superior quality, than molasses not treated with zeolite. F. W. ZERBAN

Studies upon starch. C. L. ALSBERG. *Ind. Eng. Chem.* 18, 190-3(1926).—"Evidence is presented in support of the view of Harrison (*C. A.* 6, 298) and others that starch heated in H₂O suspension does not, for most species, disintegrate to form a colloidal soln. The starch granules merely swell. The process is a gradual one; the 'gelatinization point' cannot be regarded as a characteristic const. of a starch variety. Most boiled starches are suspensions. Their viscosity is that of a suspension rather than that of a true colloid soln. Anything which disintegrates the granules greatly lowers the viscosity of boiled starch. If natural, untreated starch is ground in a pebble mill until most of the granules, while still recognizable under the microscope as starch, are injured, the starch becomes incapable of yielding paste in ordinary concn. A large part of the starch granule substance becomes colloidal sol. in cold H₂O. From such ground starch, without heat or the use of any reagent, clear solns. can be obtained in cold H₂O contg. material which gives the characteristic I reaction, does not reduce Fehling soln., and dialyzes through thin collodion membrane. This material is still under investigation. From the observations upon ground starch, it follows that the phys. properties of boiled starch cannot depend solely upon the colloidal properties of any of its constituents, such as amylopectin." F. W. ZERBAN

"Carboraffin" in the Sugar Industry. London, E. C. 3, 24, Monument Street: Bush, Beach & Gent, Ltd. Reviewed in *Intern. Sugar J.* 28, 47(1926).

Grape sugar from starch conversion products. W. B. NEWKIRK. U. S. 1,571,212, Feb. 2. An aq. dextrose soln. produced by conversion of starch is concd to supersatn by heating and cooling and is maintained at a temp. favorable for the production of anhyd. crystals. The mother liquor is sepd. from dextrose crystals, held at a lower temp. to induce the growth of hydrate crystals, and the latter are sepd. from the remaining mother liquor. Cf. *C. A.* 19, 746.

Apparatus for evaporating sugar juices. NAAMLooZE VENNOOTSCHAP DE NEDERLANDSCH-INDISCHE INDUSTRIE. Brit. 235,206, June 7, 1924.

29—LEATHER AND GLUE

ALLEN ROGERS

Review of the year 1925 (in leather chemistry). OSKAR RIETHOF. *Gerber* 52, 4-7(1926). H. B. MERRILL

U. S. Government master specification for sole leather. U. S. Bureau of Standards, Circ. 198 (1925).—The leather should be made from brined, green-salted, or dry-salted hides (not bull or buffalo hides) tanned with oak bark or a combination of vegetable

tanning materials. The water absorption should not exceed 25% and the chem. analysis of the moisture-free leather should show a mix. of water-sol. matter 30%, acidity (modified Procter-Searle method) 1%, total ash 2%, portion of water-sol. matter as glucose and salts 30%, portion of glucose and salts as lipson salt 50%. The hide substance must be between the limits 35 and 45%, grease 3 and 8%, and degree of tannage (combined tannin: hide substance) 60 and 80%. The moisture in the original leather must not be greater than 14%. Detailed directions for sampling are given.

B. C. A.

Some recent advances in the science of tanning. J. A. WILSON. *Gerber* 52, 3-4 *et seq.* (1926).—A review of the work of Wilson, A. W. Thomas and their collaborators since 1922.

H. B. MERRILL

Colloid chemistry in tanning - a reply. K. H. GUSTAVSON. *J. Am. Leather Chem. Assoc.* 21, 53-7 (1926).—Reply to Bancroft (*C. A.* 20, 517). Contrary to B.'s suggestion, chrome tanning cannot be explained as adsorption, which here is a meaningless term. The adsorption conception cannot explain why the combination of hide substance and Cr in a 50% basic liquor exhibits a sharp max. at 17.5 g. Cr_2O_3 per l., why this max. shifts to lower concn. with increasing basicity, why 2 further points of max. occur under certain conditions, and why sulfates and chlorides behave very differently.

J. A. WILSON

Aldehyde tannage. A. W. THOMAS, MARGARET W. KELLY AND S. B. FOSTER. *J. Am. Leather Chem. Assoc.* 21, 57-76 (1926).—Combination of CH_2O with protein is not limited to a simple 1:1 ratio, giving methylenamino linkage with amino N of the mol., but a triformal linkage with amino groups is also possible. Fixation may also take place with imino groups, so that the protein may combine with relatively large amts. of CH_2O . Combination of either CH_2O or furfural is greatest in the p_{H} range of 7 to 9.

J. A. WILSON

Sulfur tannage. A. W. THOMAS. *Ind. Eng. Chem.* 18, 259-61 (1926).—When collagen is brought into contact with Oden's S hydrosol, it combines with the anion $x\text{S}_y\text{S}_6\text{O}_6\text{H}^-$ in a manner analogous to tanning, but does not yield a true leather. The product is more resistant to cold water than raw collagen, but readily decomposes in hot water. The combined S can be extd. from the dry material by CS_2 .

J. A. W.

Tanning skins of marine animals. CHAS. ZIEGLER. *Cuir tech.* 15, 2-4, 23-5 (1926).—A description.

H. B. MERRILL

The application of syntans. LEOPOLD POLLAK. *Gerber* 52, 1-3 (1926).—A description

H. B. MERRILL

The application of ozone in the glue and gelatin industry. II. A. KRAUS. *Chem.-Ztg.* 49, 880-1 (1925).—A method for the treatment of glue stock with O_3 to prevent decomposition.

ERWIN J. KERN

The differentiation of hide glue and bone glue. E. SAUER. *Farben-Ztg.* 31, 721-2, 773-4 (1925).—The ash of hide glue consists chiefly of CaO and CaCl_2 ; that of bone glue is usually greater in amt. and consists chiefly of phosphates. Hide glues are mostly neutral in reaction; bone glues, more or less acid. Tannin soln. may be used as a pptg. agent instead of sulfite waste liquor as prescribed by Stein (*C. A.* 17, 2521) to differentiate the 2 varieties of glues. A concd. soln. of tannin and a small quantity of MgCl_2 and AcOH are added to a 1% soln. of glue at 50° ; hide glue produces only a turbidity; bone glue, a brown, sticky ppt. This test really indicates the different glutin content of the glues. The action of alum on glue solns. (*C. A.* 16, 3230) serves as a differentiation test when 10 cc. of a glue soln. at 30° is thoroughly shaken with 2 cc. of 5% alum soln.; with hide glue gelatinization occurs in 1 to 2 min.; with bone glue no change occurs. With glue mixts. the time required for gelatinization is an indication of the relative amt. of hide glue present. Iron alum has a stronger gelatinizing action than Al alum and the yellow gel produced with hide glue is streaked with red and white which serves as a further differentiation from bone glue. Hide glue, after sufficiently long heating, shows similar phys. properties and the same reactions with alum as bone glue. The difference between these 2 glues consists not only of different glutin content but also of other attendant components.

F. A. WERTZ

The chemistry of adhesive substances. G. M. DYSON. *Chem. Age* (London) 13, 488-90, 512-4 (1925).—I. An account of the manuf. of glue from hides, bones and fish waste is followed by a description of the properties of glues, and finally the more important tests for quality in glues are briefly outlined. II. The following methods of testing glue are described: fusion point by the Cambon fusimeter by which the "glue index" is worked out, the "gold number" test, thionine blue test for glue and agar in foods, the "gelometer" test for strength, the dynamometer test on glued joints. The following coagulation processes for the prepn. of casein are briefly de-

scribed: (1) mineral acids, (2) vegetable acids, (3) rennin. The nature and properties of casein and processes for the prepn. of glues from casein, the uses of dextrin and the nature of and uses for the vegetable gums are all briefly dealt with. E. G. R. A.

The manufacture and properties of sulfonated fish oil and sulfonated neatsfoot oil (STIASNY, RIESS) 27.

ARNOLD, JOHN RANDALL: **Hides and Skins.** Chicago and New York: A. W. Shaw Co. 606 pp.

Treating waste chrome leather, etc. J. MAYER & SOHN. Brit. 235,518, June 16, 1924. Waste chrome leather is subjected to oxidation, preferably by heating in an autoclave with BaO_2 , to convert the Cr to hexavalent form. Ba chromate and BaSO_4 are sepd. from the glue liquor and treated with NaHSO_4 or Na_2SO_4 and H_2SO_4 or HCl to produce Na chromate. Waste chrome tanning liquor is treated with BaCl_2 or Ba(OH)_2 or with a Pb or Sr salt to produce an insol. chromate which is sepd. and converted into Na chromate.

Fibers from skins. A. EHRENREICH and K. BENDIXON. Brit. 235,050, Aug. 25, 1924. In obtaining long fibers of great strength, silk-like appearance and high H_2O -resisting properties, prickles or horn plates are first removed from the skins of chondropterygians and plagiostomes. The skins are then swelled with Na sulfide soln. and reduced to fibers by a tool faced with needles. Waste of tanned skins may be used. The fibers may be rendered more durable by treating either them or the skins from which they are produced with an ext. from the gastric juice or urine (or both) of the fish from which the skin was obtained. By grinding the fibers and mixing them with an agglutinant such as glue obtained from the same fishes, a material adapted for elec. insulation or for resisting heat or moisture is obtained and, with addn. of formaldehyde and use of pressure, a hard material for making gramophone disks and the like is produced.

Tanning. T. BLACKADDER. U. S. 1,571,873, Feb. 2. In prepg. a tanning material from waste sulfite liquor, digester liquor is treated with slightly more lime than required to neutralize it, the ppt. formed is sepd., the liquor concd. and H_2SO_4 added to ppt. the lime.

Tanning hides. O. RÖHM. Brit. 236,483, Feb. 12, 1925. Before tanning, hides are treated with a mixt. of NaCl and NH_4Cl (or other suitable salts of alkalies or alk. earths) in the presence of acid and then treated with NH_3 (which in part may be replaced by other alkali). The skin may be treated with enzymic substances from pancreas either before or after the treatment with NH_3 and the NH_3 may be formed *in situ*. This treatment removes the hair and may be followed by plumping and bating treatments.

Depilating hides. M. BERGMANN. Brit. 236,543, July 2, 1924. $(\text{NH}_4)_2\text{S}$ is used as a depilating agent together with a sol. silicate.

Casein waterproof glue. A. A. DUNHAM. U. S. 1,571,662, Feb. 2. A casein waterproof glue is mixed with 5–20% of wood flour, which serves to avoid discoloration of wood on which the glue is used.

Subdividing glue, etc. AKT.-GES. FÜR CHEMISCHE PRODUKTE VORM. H. SCHEIDEMANDEL, D. SAKOM and P. ASKENASY. Brit. 235,263, Feb. 28, 1924. Glue, gelatin or the like is obtained in small beads or grains by passing its soln. in the form of drops through a cooling liquid comprising an aq. or other miscible liquid, gases or gaseous mixts. or immiscible liquids such as C_6H_6 , Cl derivs. of hydrocarbons, CS_2 or benzyl alc., which may be followed by treatment with cleansing liquid.

Glue, gelatin and fish meal. J. C. KERNOT. Brit. 235,635, March 18, 1924. Fish offal or the like is washed successively with running H_2O , dil. alk. solns., H_2O and dil. acid solns. to prep. the material for glue or gelatin extn. The residue is formed into meal.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The rubber industry during 1925. S. A. BRAZIER. *Ind. Chemist* 2, 18–20(1926). E. H.

The viscosity of rubber solutions. RUDOLF DITMAR. *Rubber Age* 18, 317(1926).—English version of a previous article (cf. C. A. 19, 3193). C. C. DAVIS

Has the serum of Hevea latex any value? W. SPOON. *Arch. Rubbercultuur* 9,

937-47(1925).—Latex probably contains about 1.5% quebrachitol. The proportion of it passing into the serum, detd. by a method already given (*C. A.* 17, 650), is increased by diln. of the latex before coagulation (cf. Contardi, *C. A.* 19, 1135). F. H. Y.

Vulcanization in hot air. B. BUIZOV. *India Rubber J.* 71, 99-100(1926).—See *C. A.* 20, 312. C. C. DAVIS

Effect of accelerators on cure and quality of various rubbers. R. P. DINSMORE AND A. O. ZIMMERMAN. *Ind. Eng. Chem.* 18, 144-57(1926).—Systematic tests of rubber vulcanized with and without accelerators indicate that the rate of cure is not in itself sufficient for judging the quality of a rubber. Adequate judgment can best be obtained with the aid of 3 criteria, viz, the rate of cure, the rigidity (the "stiffness index") and the resistance to tearing at the best cure. This best cure, necessarily empirical, is that at which the rigidity and resistance to tearing are most properly balanced and when aging is at the same time satisfactory. The influence on these properties of various individual accelerators could not be correlated so that any general conclusions could be drawn. C. C. DAVIS

Dyes [for rubber] (*Brit. pat.* 235,169) 25.

Rubber latex. AMERICAN RUBBER CO. *Brit.* 235,888, June 18, 1924. Thickened and stabilized latex for spreading, dipping, molding, etc. is prepd. by treating latex with Na or K silicates or other thickening agent having also a coagulating action and also with a coagulation preventive such as NH_3 soln. or an NH_4 compd. Fillers, vulcanizing ingredients, accelerators, etc., also may be added.

Treating rubber latex. AMERICAN RUBBER CO. *Brit.* 235,232, June 9, 1924. Thickened and stabilized rubber latex compns. for extruding, spreading and dipping purposes are prepd. by adding to latex a non-protein substance which will thicken the aq. phase and stabilize the latex without substantially modifying the colloidal condition of the rubber hydrocarbon. Or, a substance may be used which reacts chemically with the H_2O -sol. constituents of the latex (especially with the latex sugar) but preferably does not attack the proteins. Pb thiosulfate, basic Pb acetate, Pb acetate with a protective agent, PbO, Pb hydroxide, Pb_3O_4 , reaction products of Pb oxides or salts and mono-, di- and polysaccharoses, Pb chloride, Bi hydroxide, Fe_2O_3 , ferrous lactate, basic ferric acetate, ferrous oxalate, stannous oxalate and CdS may be used; or, thickening agents such as NH_4 soaps may be used as may also saponin, glue, oils, fillers, etc. *Brit.* 235,233 specifies compns. contg. rubber and ingredients which impart "tackiness," prepd. by mixing latex or similar aq. rubber suspension with an easily decomposable H_2O -sol. compd. of the other ingredient and afterward decomposing this compd. and removing the portion rendering it sol. Pine tar, coal tar, hardwood pitch or rosin may be used and rendered sol. by combination with NH_3 or an amine. A shoe cement may be formed of latex, NH_4 resinate, H_2O , PbO and S.

Distilling rubber. M. K. BAMBER. *Brit.* 235,380, June 5, 1924. Waste crude scrap or vulcanized rubber is heated in a still to not over 350° under a pressure not exceeding 2 atm. until $1/2$ - $2/3$ of the charge is vaporized. The distillate is condensed at about atm. pressure; it is a liquid consisting mainly of crude dipentene. Gas produced is led to a furnace for heating the still and the liquid residue is used as a substitute for drying oils. Increase of pressure in the still reduces the yield of dipentene. *Brit.* 235,381 relates to paints, varnishes, etc., made with the liquid rubber still residue after it has been given a preliminary treatment with air. This material also may be used in compns. for treating roads.

Tubing from latex. E. HOPKINSON and W. A. GIBBONS. U. S. 1,570,895, Jan. 26. Rubber latex is formed into a tube by extrusion through a die and the walls of the tube are supported by a core of liquid such as HOAc or alc. during coagulation. Cf. *C. A.* 19, 2760.

Rubber vulcanization accelerator. W. SCOTT. U. S. 1,571,739, Feb. 2. An accelerator is formed by the action of formaldehyde on the condensation product obtained from acetaldehyde 3 and aniline 2 mol. proportions.

Rubber vulcanization. V. LEFEBURE and A. J. HAILWOOD. U. S. 1,570,752, Jan. 26. A vulcanization accelerator comprises a stable compd. of a *p*-nitrosoalkylarylamine such as *p*-nitrosodimethylaniline and 2 mol. proportions of β -naphthol.

CHEMICAL ABSTRACTS

1 - APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Sedimentation analysis. I. SVEN ODÉN *Tekn. Tids.* **55** (Bergsvetenskap afd.), 65-8(1925), cf. *C. A.* **14**, 2116. Suggesting a practical application of an automatic electric recording device for measuring particles 10 μ and less by the rate of sedimentation.

A. R. ROSE

The accuracy of graduated measuring vessels. II. H. V. RENN *Ind. Chemist* **2**, 30-1(1926), cf. *C. A.* **20**, 847. — (1) The "Bull" or one mark pipet. R. discusses the methods of delivery generally practiced and the magnitude of the errors resulting from each method, the influence of delivery time and drainage time (graphs), the dimensions recommended by the Comm. of Standardization of Lab. Glassware and the method of testing at the National Physical Lab. (2) The buret. The best methods of graduation, the effect of unevenness of bore, time of delivery and of draining (graph), method of testing at the National Physical Lab. and tolerances are discussed. (3) The graduated pipet. Time of delivery, method of testing and tolerances are treated briefly.

E. G. R. ARDAGH

A circulation apparatus for gases. NITYA GOPAL CHATTERJI AND GEORGE INGLE FINCH *J. Chem. Soc.* **127**, 2461-6(1925). The app. is an improvement of that of Bone *J. Chem. Soc.* **81**, 1903(1902) and may be used to circulate gases or liquids. Two non return Hg valves are joined by a capillary tube which, leading from above the Hg of the 1st valve, dips into the Hg of the 2nd valve. The gas or liquid passes down a capillary through the 1st valve, thence through the capillary into the 2nd valve and out of the top of the latter. Between the valves the capillary connects with a U-tube, in the more remote end of which is a plunger piston. The U-tube is partially filled with Hg, so that downward motion of the piston raises the Hg in the other end of the U-tube and the pressure drives gas into the 2nd valve, the Hg seal in the 1st valve preventing passage backward. On return of the piston, the Hg descends, and gas is sucked in through the 1st valve, the Hg seal of the 2nd valve preventing suction from the 2nd valve. With a U-tube of 1.5 cm. bore, 162 l. per hr. can be circulated. Various precautions and refinements are described and the app. is illustrated.

C. C. DAVIS

Automatic apparatus for determining the melting point of organic compounds. E. B. MACMULLIN *J. Am. Chem. Soc.* **48**, 139-42(1926). An adaptation of Dubose's app. (*C. A.* **19**, 1514) which automatically and accurately records the m. p.

Tests with molybdenum steel balls at Matahambre, Cuba. E. C. CLAPP AND F. C. DEVEREAUX *Eng. Mining J. Press* **120**, 891(1925). — Ball-mill tests gave a ball consumption about $\frac{1}{4}$ smaller with Mo treated Cr-steel balls than with ordinary Cr-steel balls.

A. BUTTS

Electrochemical actinometers. GEORGES ATHANASIU *Ann. phys.* **4**, 319-424(1925); cf. *C. A.* **19**, 1356, 2761. — A thorough study of the influence of light and heat on voltaic cells is made. Polarized electrodes show irregular changes. Reversible cells (Ni, Cu, Hg) show uniformly 2 superimposed effects if 1 electrode is exposed to light. One is a chem. change, disappearing immediately with the end of the illumination period. The other effect is caloric and increases with time. Illumination of the electrolyte produces only the second effect while the first one is generally connected with a tarnished electrode surface. The method of measurement permits detecting currents of the order 10^{-10} , which excludes photoelectric currents on account of their low range. A special study is made of electrodes covered with coatings sensitive to

light (Ag, Hg, CuO). A radiation separator is constructed for the wave lengths $3\ \mu$ to 2000 A. U. and the sensitivity curves of these actinometers are detd. J. T. S.

The discovery of the chemical elements masurium and rhenium. ERNST RÜST. *Tech.-Ind. Schweiz. Chem.-Ztg.* **1925**, 234-9.—A brief description of the methods of X-ray spectroscopy and of their application to the discovery of elements 43 and 75 (masurium and rhenium). W. B. PLUMMER

Thirty-second annual report of the Committee on Atomic Weights. **Determinations published during 1925**. G. P. BAXTER. *J. Am. Chem. Soc.* **48**, 541-52(1926); cf. *C. A.* **19**, 1070.—The elements particularly discussed are He, B, C, O, Al, Si, Cl, Cu, Ge, Se, Br, Sb, Ho, Hf, Au and Pb. E. J. C.

The density and atomic weight of helium. II. G. P. BAXTER AND H. W. STARK-WEATHER. *Proc. Nat. Acad. Sci.* **12**, 20-2(1925).—Improved measurements over those in *C. A.* **19**, 1643, involving the use of 2-l. flasks and a corrected value for the force of gravity, give for the d. of He 0.17846 instead of 0.17845 at atm. pressure and 0.08923 at $1/2$ atm. Since the av. d. of He at $1/2$ atm. pressure is exactly half that found for 1 atm. He obeys Boyle's law over this range. The at. wt. of He is remarkably near the value 4.000 with some uncertainty in the 4th decimal place. GEORGE L. CLARK

The determination of the formula of carbon dioxide. W. L. EVANS, J. B. PETERSON, H. B. HASS, G. P. HOFF AND J. E. DAY. *J. Chem. Education* **2**, 932-5(1925).—A lab. expt. for students in general chemistry is described. E. H.

Increase of tensile strength and recovery of zinc crystals. F. SCHMID. *Z. Physik* **32**, 918-21(1925).—The tensile strength increases with plastic deformation, but this action is partly reversed if the crystal is allowed time to recover. B. C. A.

Structure of stearic and stearolic acids. A. MÜLLER. *Nature* **116**, 45 (1925).—Stearic acid crystals, obtained from a satd. soln. in CS_2 , are monoclinic. The dimensions of the unit cell are: a 5.60, b 7.38, c 50.9 A. U., β 59.7°; d slightly above 1.05, indicating 4 mols. to the unit cell. A crystal of stearolic acid appeared to be triclinic. B. C. A.

Measurement of the amount of ozone in the earth's atmosphere. G. M. B. DOBSON AND D. N. HARRISON. *Proc. Phys. Soc. London* **38**, 74-6(1925).—With O_3 having a strong ultra-violet absorption band at wave lengths below 3300 A. U. with a max. at 2850 A. U., it has been detd. in the atm. by the variation of the intensity of a

no. of the Fraunhofer lines in this vicinity, a Br + Cl filter being used to remove wave lengths of over 3300 Å. U. The amt. of O₃ in the atm. (necessarily in arbitrary and undefined units) varies 50% between its max. and min., the change following that of the inverse barometric pressure with considerable accuracy. W. B. PLUMMER

Determination of the viscosity of sulfur dioxide and its mixtures with hydrogen. MAX TRAUTZ AND WALTER WEIZEL. *Ann. Physik* 78, 305-69(1925).—The viscosities of SO₂, H₂, air and 16 mixts. of SO₂-H₂ (varying in concn. from 82.15% to 15.12% SO₂) were detd. from the rate of flow through very short glass capillaries. T. and W. found that the Hagenbach correction for kinetic energy is applicable to gases. A further correction was necessary to take account of the variation from the ideal gas. The coeffs of viscosity of air were detd. between 14 and 199° and found to conform generally with Sutherland's formula. The Sutherland const. was found to be a function of the temp. and pass through a max. in the middle temps. The temp. coeffs of SO₂ between 14 and 199° are fairly const. This gas deviated from the Sutherland formula in direct proportion to its deviations from the ideal gas. In the mixts SO₂-H₂ the viscosity passes through a max. which tends to become less pronounced with the increase in temp. while shifting toward the mixts. richer in SO₂. The increase is approx proportional to the mole fraction of H₂ until the max. value is reached. The viscosity is very similar to that of SO₂ until this point is reached. T. and W. could not det. from their data that the viscosity of gas and gas mixts could be classified as a "corresponding property." They formulate the thesis for further investigation of this problem as follows: Is it the relation of the crit temps of the components of gas mixts which det. the shape of the mole fraction diagram or the corresponding temps of the less ideal gas? The error in measuring the viscosities did not exceed 0.15% (air), 0.2% (SO₂, H₂) and 0.4% (SO₂-H₂). The values for H₂ are larger than those of Klemm and Volker, agree with those of Breitenbach and are smaller than those of Thomsen, Puli, and Graham. Diagrams of app. for measuring flow, mixing the gases and gas generator (SO₂) are given.

E. R. SCHIERZ

The derivation of the equation of state from the specific heat. LÉON SCHAMES *Physik. Z.* 26, 731-2(1925); cf. *Ann. Physik* 57, 321(1918).—In an attempt to derive an equation of state from Clausius' equation: $(\partial C_p / \partial p)_T = -A \cdot T (\partial_2 V / \partial \partial_2)_p$, with the exptl. data of C_p (as a function of the temp. and pressure), the difficulty lies in the detn. of the integration const. The lower temp. limits are functions of the pressure. In the Avogadro state (pressure = 0), the lower temp. limits are those of the Joule or

Boyle points. L. has obtained the equations. $V = (RT/P) - (1/A) \int_{II}^T dT \int_{IIIa}^T (1/T)$ $(\partial C_p / \partial P)_T dT$, where II is the Boyle point, and IIIa is given by the equation $(\partial V / \partial T)_p = R/P$. J. H. PERRY

The validity of equations of state. II. W. HERZ. *Z. Elektrochem.* 32, 31-3 (1926); cf. *C. A.* 19, 1073.—The equation of Berthelot: $PV = RT\{1 + 0.0703 \cdot (T_K P_K / TP)[1 - (6T_K^2 / T^2)]\}$, and that of Wohl: $PV = RT\{1 + 0.0667(T_K P / TP_K) \cdot [1 - 6.40(T_K^2 / T^2)]\}$, have been shown to reproduce exptl. data with very good precision, when not too high pressures are used. Both equations are of about the same validity, although H. slightly favors the equation of W. With increasing temps., the PV -product goes through a min. The ratio of the temp. corresponding to this min., to the crit. temp. is a nearly const. quantity for the 13 substances investigated. J. H. P.

Kinetic activation as a factor in gas reactions. WILFRID TAYLOR. *Trans. Faraday Soc.* (advanced proof), Jan. 18, 1926.—The velocity of activation by different types of collisions, s , is $K = sII_2\{\epsilon/kT + 1\}e^{-\epsilon/kT}\sqrt{T}$, where ϵ is the activation energy and

$II_2 = 2p_1v_1\sigma^2 \sqrt{2k\pi(m_1 + m_2)/m_1m_2}$, where v_1, v_2 are the concns. of the 2 particles colliding, σ is the sum of the radii, and m_1 and m_2 are the resp. masses. D. S. V.

The measurement of the vapor pressure of carbon. F. BORN. *Z. tech. Physik* 7, 24-31(1926).—A crit. review with bibliography. E. H.

Determination of vapor pressure of carbon. H. ALTERTHUM AND F. KOREF. *Z. Elektrochem.* 31, 658-62(1925).—The difference in results in the detn. of the vapor pressure curve of C by the arc method and that involving the measurement of velocity of vaporization is to be ascribed partly to the different velocities of break down of different crystal faces but more particularly to the presence of an adsorption layer of higher concn. than corresponds to the vapor pressure. By consideration of the compn. of this layer it is possible to calc. the accommodation coeff., the vapor pressure curve of the adsorption layer, and the heat of adsorption of C. The latter is 51,900 cal./mol. or

about $\frac{2}{3}$ of the mol. heat of vaporization. No new expts. are reported but the results are obtained by analogy to the exptl. results on metals and C of Langmuir, Knudsen, Lummer, Fajans, Gross, Koref and Moers and others.

GEORGE L. CLARK

The vapor pressures of solid and liquid hydrogen cyanide. J. H. PERRY AND FRANK PORTER. *J. Am. Chem. Soc.* **48**, 229-302(1926).—The HCN, prepd. from KCN and H_2SO_4 , was purified by fractional distn. at low temps. The vapor pressures of the solid were detd. from -30.4° to the triple point; and for the liquid from the triple point to $+27.32^\circ$. The data for the solid and liquid, resp., are represented by the equations: $\log_{10} P_{(\text{mm})} = 9.33902 - (1861.8/\tau)$ and $\log_{10} P_{(\text{mm})} = 7.711603 - (1453.063/\tau)$. The triple point is calcd. to be -14.86° at a vapor pressure of 131.16 mm. The normal b. p. is $+25.65^\circ$. The latent heats of sublimation, fusion and evapn are 316.13, 69.29 and 216.84 cal. per g., resp.

J. H. PERRY

A simple formula for calculating the critical temperature from the expansion coefficient in the liquid phase, and the reason for its non-applicability for many molten salts. J. J. VAN LAAR. *Z. anorg. allgem. Chem.* **146**, 263-80(1925).—A formula is derived with which it is possible to calc. from the slopes of the rectilinear diams. and the ds. at zero abs. the crit. temps. of liquids. The formula has the form $T_k = 1/r\alpha$, where T_k = the abs. crit. temp., α = the expansion coeff. referred to the d. at zero abs. ($D = D_0(1 - T)$), and r = a function of γ the slope of the rectilinear diam. ($r = (1 + \gamma)/\gamma$). This formula holds exactly only for substances the rectilinear diams. of which are straight lines. This is not the case with salts like the alkali halides whose vol. in the liquid phase is considerably less than the sum of the at. vols. of the constituent elements. Their crit. temps. must be detd. by other methods. Van L. has calcd. for the alkali halides the ratio D_0/D_c , where D_0 is the extrapolated liquid d. at zero abs. and D_c is the liquid d. at the l. p. Except for Li halides this ratio is roughly a const., 1.37. The mol. vol. at zero abs. is calcd. by the formula $\tau_0 = M/D_0 - 22416$, where M is the mol. wt. The values of τ_0 calcd. for the alkali halides were considerably less than the sums of the τ_0 values of the individual elements in the compd.

R. L. DODGE

The additivity of the molecular volumes of liquid inorganic compounds. EUGEN RABINOWITSCH. *Ber.* **58B**, 2790-8(1925).—By examn. of the data from org. compds. R. concludes that the at. vol. for all elements of the first period is 5.5; for the second period 11; for the third 23, for the fourth 28 and for the fifth 37.5. These vols. are about 5 less than the at. vols. of the inert gases of the corresponding periods, except for the first period, in which He forms an exception. R. applies this rule to 50 inorg. compds., finding only a few exceptions, these are discussed at length. Unsatur. increases the mol. vol. to the extent of 1.5 for each missing H atom, strong association decreases the vol.

B. H. CARROLL

Surface tension of water, benzene, methanol and ethyl alcohol. B. ALI. *Proc. Indian Assoc. Cult. Sci.* **9**, 155-78(1925).—The capillary-tube method of measuring surface tension is modified by detg. instead of the rise of liquid in the capillary, the pressure which must be applied to the surface of the meniscus in order to depress it to the level of the horizontal surface of the liquid outside the tube, or to an arbitrary mark at a known distance below the free surface of the liquid. The pressure was measured by a sensitive differential manometer. The values of the surface tension of the above 4 liquids at 29.5° were, resp., 71.32, 28.10, 23.30, 21.32 dynes/cm. The advantages of the method are discussed, and the av. error in measurement is estd. as 1 part in 9000.

B. C. A.

Some phenomena of capillary chemistry. RENÉ DUBRISAY. *Compt. rend.* **181**, 1142-3(1925); cf. **18**, 490, 1074, 3131. D. had proposed the hypothesis that a fatty acid is the more active in depressing the interfacial tension between C_6H_6 and an alk. soln. the less sol. is its alkali salt. Supporting this, the vol. of the drops from a buret contg. the C_6H_6 solns. of palmitic, stearic and oleic acids, resp., discharging in 0.001 N NaOH, increased with temp., though in H_2O they decreased with temp.

A. W. FRANCIS

Surface tension of aqueous solutions of the alkali halides. F. DE BLOCK. *Bull. sci. acad. roy. Belg.* [5], **11**, 333-52(1925). Surface tensions have been detd. for solns. of NaCl, NaI, KCl, KBr, KI, LiCl, LiBr, LiI, and NH_4Cl for various concns. up to near the satn. point by the drop-wt. method. The rule of Quincke, that solns. of alkali halides contg. the same amt. of the given halogen have the same surface tension, is verified by the data. Conclusion: none of the proposed methods for relating surface tension to concn. can be used by extrapolation to det. that of the pure salt. The Li halides are shown to be somewhat abnormal from the present standpoint.

W. B. PLUMMER

Influence of temperature on the surface tension of liquids. F. DE BLOCK. *Bull.*

sci. acad. roy. Belg. [5], **11**, 292-300, 353-60(1925).—The equation for the surface tension α and the temp. t ($^{\circ}\text{C}.$) may be written $\alpha = K(t_k - t)^n$, where t_k is the crit. temp. and $K = \alpha_o/(t_k)^n$, and where n is approx. 1.20. Certain available data for C compds between -79° and 176° , and for liquefied gases in the range -258.5° to 50° have been applied to the further testing of this equation for low temps. The relation is verified by data representing the liquid in contact with its vapor, but not by the surface tension of liquids in contact with inert gases.

W. B. PLUMMER

A theory of the adsorption of gases. ÉMANUEL JAQUET *Fortschritte Chem.* **18**, 437-90(1925). This is a theoretical and mathematical paper having for its object the development of a general theory for the adsorption of gases leading to an equation for the "adsorption isotherm" based on probability considerations and independent of any assumptions concerning the nature of the forces involved in adsorption. In addn., a method is shown for computing the energy of adsorption from the tangent to the isotherm at the beginning of the adsorption. The energy of adsorption is explained as an electrostatic energy, and with the aid of elec. concepts a relation is found between the elec. const. of the mols. and the energy of adsorption. The significance of the adsorbent is discussed. Finally the new theory is applied to numerous sp. cases taken from the literature and it is shown that the principle set forth appears to be correct.

F. L. BROWNE

Adsorption power and electrical behavior of different preparations of charcoal. I. OGAWA *Biochem. Z.* **161**, 275-91(1925). A comparison of the adsorption properties of charcoal from blood, sugar, gelatin, naphthalene and paraffin is made, with moisture, phenol, I, HCl, NaOH, org. dyes such as methylene blue and eosin, and Congo red, picric acid, and octyl alc., as the adsorbed substances. Then the relative elec. charge upon the charcoal particles is detd. by the method of elec. endosmosis. The adsorption power has no relation to the ash content, is raised by preliminary heating, and varies probably because of the chem. and phys. constitution of the C. W. D. L.

Adhesive forces in solutions. VI. Experimental data on adsorption from mixed solvents. NIKOLAI SHILOV AND SOPHIE PEYSNER *Z. physik. Chem.* **118**, 361-8(1925), cf. *C. A.* **14**, 1775, **20**, 531. The adsorption of salts and morg. and org. acids by activated charcoal in mixed solvents has been studied. The curves which show the relation between the amt. adsorbed and the compn. of the mixed solvent are similar to curves which show the changes in properties (d., vapor pressure, cond. of dissolved electrolyte, surface tension, etc.) of the mixed solvent with change of compn. For alc.-water mixts., the adsorption curves of most salts and inorg. acids drop from the adsorption values in the pure components to a min., while the curves for org. acids vary without inflection between the values for the pure solvents. In mixts. of solvents which contain no water (alc.-ether, toluene-alc., toluene-ether) the adsorption curves for all substances, with a few exceptions, show minima. The amt. of adsorption is much less in mixed solvents than in either pure solvent, in many cases. Although there seems to be a definite relation between adsorbability and soly. of substances in a certain solvent, other factors interfere to make the process of adsorption very complicated.

R. J. HAVIGHURST

Some rhythmic phenomena in the precipitation of suspensions of red mercuric sulfide. N. I. MOROSOV, *J. Trans. Russian Chinese Polytech. Inst. Harbin*, No. **4**, 135-9(1925); cf. *C. A.* **19**, 1647. Suspensions of red HgS were prepd. by von Veimarn's method. A portion of the sulfide was rubbed in a mortar with milk sugar (1 part of HgS and 10 parts milk sugar) for 10 hrs. The powder produced was mixed with water and shaken for the dissolution of the sugar. After some time peculiar strata in the suspension were formed, similar to those of Ag_2CrO_4 in a gel of gelatin (Liesegang's strata). These were unchanged by gentle but disappeared with vigorous shaking. N. v. P.

Fractional precipitation. II. Topochemical influences in the separation of manganese and zinc by sodium sulfide. OTTO RUFF AND BRUNO HIRSCH, *Z. anorg. allgem. Chem.* **150**, 81-98(1925). The soly. product of MnS being 10^8 times that of ZnS , the fractional pptn. of Zn by Na_2S in the presence of Mn should present no difficulty, according to the previous work (cf. *C. A.* **19**, 3195). Mn salts do not dissolve any Zn out of pptd. ZnS ; however, MnS is never totally transformed into ZnS by Zn salts; the ratio decreases with the age of the MnS , increases with higher dispersion and lower temp., and is independent above a certain level of the Zn concn. This is explained by an impermeable coat of ZnS around the MnS crystals, lowering the reaction speed toward 0. The Mn content of the ppt. from a neutral sulfate soln. can be lowered to 0.2% if a high Zn/Mn ratio is pptd. by dil. Na_2S soln. under efficient stirring and at low temp. Presence of alkali salt or washing after pptn. changes the result little; subsequent boiling improves it somewhat.

JOHN T. STERN

Growth of structures formed by reactions on the boundary between solutions of electrolytes in water and those in gel. VLADIMÍR MORÁVEK. *Spisy Přírodovědeckou Fakultou Masarykovy Univ.* 1925, No. 59, 3-40.—If 0.1 N $\text{Pb}(\text{NO}_3)_2$ is placed over a solidified 0.1 N $\text{K}_2\text{Cr}_2\text{O}_7$ in 5% gelatin, fibrous structures 0.1-0.3 mm. wide grow out into the former. The fiber wall is formed of gelatin on which is pptd. PbCrO_4 . Through the fiber flows a stream from the gelatin layer that meets the $\text{Pb}(\text{NO}_3)_2$ soln. at the end of the fiber structure. There is always pptd. first a gelatin layer in the form of a membrane on which PbCrO_4 is deposited discontinuously and which grows with a max. velocity of 0.16 mm. per min. The chief growth directions are vertical and horizontal: if neither prevails, the fiber grows ladder- or stair-like, and exceptionally it is spiral-shaped. The vertical growth velocity is always greater than the horizontal. The growth velocity, dimensions and shape of the fibers are influenced by all the factors which can affect the properties of lyocolloids, e. g., concn. of gelatin, substitution of chromate for dichromate, addn. of K^+ or Ca^{++} , increasing the rate of reaction, raising the temp. above 32° . Neither change in intensity of an incandescent lamp nor light of definite wave lengths of the visible spectrum exerts any influence. The cause of the growth of the fiber is the diffusion stream towards the place of the reaction between Pb^{++} and CrO_4^{--} and simultaneous soln. of gelatin into a sol accompanying the reaction. This diffusion stream forms a small channel the walls of which are filled up by pptd. gelatin and PbCrO_4 deposited on it. Above the gelatin layer the channel is prolonged into a fiber. M. draws attention to the similarity of the structure and changes in shape of the fiber and the anatomical and morphological characteristics of vital processes. A. P.-C.

Application of X-ray methods to the problem of imbibition. J. R. KATZ. *Physik Z.* 25, 659-66(1924).—A general review of the possibilities of X-ray technique as a means of elucidating the problems associated with the phenomena of imbibition. B. C. A.

Colloidal silica. B. WASSER. *Metallforsch.* Nov. 11, 1925, *Ind. Chemist* 1, 518 (1925).—W. discusses some of the general properties of silica gel and a few points to be remembered in its manuf., and cites a no. of fields of usefulness. E. G. R. ARDAGH

Influence of the hydrogen-ion concentration upon the velocity of flocculation of a few negative colloids. A. BOUTARIC AND MME. Y. MANIÈRE. *Compt. rend.* 181, 913-5(1925).—The influence of HCl , HBr , HI , HNO_3 , HPO_3 , CH_3COOH , CCl_3COOH , H_2CO_3 , H_2SO_4 , $(\text{COOH})_2$, lactic, tartaric and succinic acids on the flocculation of 3 sols at equal p_{H} is studied. With a gamboge suspension HI , HPO_3 , H_2CO_3 , CH_3COOH and CCl_3COOH show curves deviating from the common curve of the other acids. With mastic rosin only HCl , HBr , and HNO_3 coincide, but all unite at high dilns. With As_2S_3 sol $(\text{COOH})_2$ and H_2SO_4 are close together and HNO_3 , HPO_3 and CCl_3COOH are apart. These variations may be explained either by changes in the velocity of the H ions in these solns. or by an influence of the anions. This influence would also explain the effects related in earlier papers (cf. C. A. 19, 2767). JOHN T. STERN

General colloid chemistry. XVII. The analysis and constitution of colloidal gold (3). LEOPOLD FUCHS AND WOLFGANG PAULI. *Kolloidchem. Beihefte* 21, 195-240(1925); cf. C. A. 19, 3401.—Au hydrosols prepd. by reduction of Au salts in slightly alk. soln. with HCHO or H_2 , when thoroughly dialyzed, become slightly acid in reaction. The c_{H} detd. by electrometric titration of the sol with $\text{Ba}(\text{OH})_2$ reached a const. value at about 1×10^{-6} N. Examn. of the ultrafiltrate or of the supernatant liquid after coagulation revealed no Cl^- . The c_{H} value was not due to CO_2 dissolved from the air, to SiO_2 from the glass vessels, or to colloidal org. acids dissolved from the parchment paper dialyzer. The H ions are regarded as the "contra-ions" for the negative Au particles. The Au particles are conceived to be coated with a layer of an auric acid whose disson. provides the H^+ ions and leaves the particles negatively charged. Zsigmondy's theory that the "contra-ions" are Au^{+++} is disproved by the inability to find Au in the ultrafiltrate or the supernatant liquid after coagulation. Since the H ions are the "contra-ions" for the charged particles it is possible by counting the no. of particles per unit vol. to arrive at the av. no. of charges per particle from the detn. of c_{H} . For HCHO sols this was found to be 46,630 and for H_2 sols 35,000. However, if only a very small quantity of the Au is present as amicros, these nos. will be very greatly reduced. The concns. of AlCl_3 and BaCl_2 required to coagulate the HCHO sol were 1.28×10^{-4} N and 1.4×10^{-3} N, resp., and for the H_2 sol 1×10^{-4} N and 1.16×10^{-3} N.

F. L. BROWNE

The colloid chemistry of bismuth and its compounds. A. KUHN AND H. PIRSCH. *Kolloidchem. Beihefte* 21, 78-96(1925).—By changing the dispersity of a therapeutically active substance it is often possible to suppress an undesirable property, such as cauterizing action or painfulness due to protein coagulation, without losing the therapeutic value. Aq. solns. of Bi compds. have not been useful in therapy because of their pain-

fulness. Methods of making colloidal Bi and Bi compds. were studied with a view to their possible use in medicine. *Prepn. of Bi sols.*: Stable sols contg. as much as 3.5 mg. Bi per cc. were made by reduction of solns. of Bi salts with NaHSO_3 in weakly alk. soln. *Prepn. of Bi_2S_3 sols.*: Protective colloids were required to produce stable sols of sufficiently high concn. With 1% gum arabic, sols contg. 10 mg. Bi per cc. were made. *Prepn. of BiSI sols.*: Protective colloids were required to obtain sols contg. 0.3 to 1.6 mg. Bi per cc. 0.5% gum arabic, 0.5% hemoglobin, and 0.25% gelatin were found suitable. *Prepn. of sols in oil of sesame.*: Quite highly dispersed sols were made by incorporation of Bi compds. in wool fat, cooling in liquid air, and vigorous trituration of the mixt. On dissolving in oil of sesame, stable sols resulted. Sols of Bi_2S_3 , BiSI and Bi(OH)_3 were prepd. contg. 12–16 mg. Bi per cc. and 20% wool fat. *Prepn. of sols by elec. dispersion.*: By the Bredig method, stable sols contg. 8 mg. Bi per cc. and 5% wool fat, and sols with 0.6 mg. Bi per cc. and 1% soln. of rubber in ether as protective colloid were made. By using Svedberg's protected arc method stable sols contg. 6 mg. Bi per cc. and 5% wool fat were prepd. F. L. BROWNE

Emulsions, their theory and practice. E. G. BRYANT. *Pharm. J.* **115**, 755–7 (1925); *Chemist & Druggist*, **104**, 6–7 (1926).—An address, with special reference to pharmacy. S. WALDBOTT

Colloidal properties of nitrocellulose sols in mixed solvents. A. HIGHFIELD. *Trans. Faraday Soc.* **1926** (advance proof).—Detns. of the soly. of trinitrophenol in ether-alc.-water mixts. support Hildebrand's amplification of Langmuir's theory, i. e., the polar alc. and water as well as the non-polar ether, are inferior in solvent power to mixts. Addn. of a precipitant, e. g., CCl_4 , to fix the solvent power of nitrocellulose solvents, led to sepn. into phases for which no phase rule diagrams exist. Therefore, recourse was had to falling-ball viscosity detns. With 4% solns. of 12.2% nitrocellulose in ether-alc.-water, viscosity max. occurred between 7 and 11% of water, the point varying with ether/alc. ratio. Similar U curves were found with acetone-alc.-water; nitrobenzene-alc.; aniline-alc.-nitrobenzene; nitroaniline-alc.; ether-MeOH-water; PrOH-ether; BuOH-ether, acetone-benzene; acetone-ether-water. Progressively decreasing N content increases the range of solvent mixts., down to 10.5%, below which soly. diminishes, as is also the case with very highly nitrated cottons. As with other colloid sols, viscosity varies with concn. "None of the general simple equations which have been proposed from time to time holds even approx. over large ranges, a result only to be expected from the complexity of the physicochem. attractions involved." Viscosity also shows an isoelectric point and aging phenomena. The best solvent mixt. contains polar and non-polar groups balanced in optimum proportions. This holds even when the constituents are not separately solvents. JEROME ALEXANDER

Certain physicochemical properties of mixtures of water and acetone. C. SANDONNI. *Atti accad. Lincei* [vi] **1**, 448–53 (1925).—The results of measurements for water-acetone mixts. of the sp. heats at 14–20°, the heats of mixing at 15°, and the sp. gravities, viscosities and surface tensions at 25° render probable the existence of mol. complexes of water and acetone, although the maxima of viscosity and heat of mixing do not correspond with any stoichiometric relation between the constituents. B. C. A.

Solid solutions of water and oxygen. N. S. KURNAKOV. *Ann. Inst. Physico-Chem. Anal. Leningrad* **2**, 482 (1924).—Striking examples of series of compds. of continuously changing compn. are the Fe compds. such as micas, tourmalines, phosphates and borates. With such compds., the gradual absorption of O and the conversion of FeO into Fe_2O_3 do not affect the homogeneity of the crystals but result in continuous variation in the color and optical properties. The mineral vivianite, consisting of a hydrated ferrous phosphate, may also be produced synthetically, and in the first stages of its formation is composed of almost colorless crystals, which retain their form and uniformity, but gradually become blue as absorption of O proceeds. The proportion of water in vivianite crystals may also change continuously, because of the formation of solid solns. of the mineral with water. B. C. A.

The partial pressures of aqueous ethyl alcohol. H. J. E. DOBSON. *J. Chem. Soc.* **127**, 2866–73 (1925).—The partial pressures of H_2O vapor and EtOH from its aq. soln. at 25° have been detd. by the dynamic method. The vapors were condensed by intense refrigeration, and their compn. was detd. by a special pycnometer. The partial pressure curves and the total-pressure curve are plotted as functions of the compn. of the liquid. The data obtained differ considerably from those of Foote and Scholes (cf. C. A. **5**, 3189) and it is suggested that there may be errors in the latter work due to the analysis of the vapors. The partial pressures of H_2O and EtOH, resp., are: for 20.51 wt. % EtOH in soln. 21.78 and 16.66 mm.; for 39.32%, 20.36 and 26.85 mm.; for 56.50%, 19.01 and 32.16 mm.; for 90.12%, 10.68 and 47.40 mm. A. W. K.

The partial formaldehyde vapor pressures of aqueous solutions of formaldehyde.

II. WILFRID LEDBURY AND E. W. BLAIR. *J. Chem. Soc.* **127**, 2832 9(1925); cf. *C. A.* **19**, 1214. The partial pressures of CH_2O from its aq. solns. free from MeOH have been detd. by the dynamic method at 35° and 45°. At the higher temps. there is a more rapid adjustment of equil. conditions in the soln., presumably between the different polymerized and hydrated forms of CH_2O . The vapor pressure curves take the form $\log_{10} p$ (mm.) = $\alpha - B/T$, where $\alpha = 9.17$, $B = 970$, $\alpha_{40} = 9.81$, $\alpha_{45} = 9.87$ and B for all cases up to 40°C. = 2905. The vapor pressures of CH_2O from MeOH soln. and from aq. MeOH soln. have been detd. at 20° and at 0° also for the latter case. It is very much higher than for aq. solns. The MeOH is presumed to bring about an alteration in the equil. between the simple and complex CH_2O mols. in soln.

A. W. KENNEY

The partial pressures of water vapor and of sulfuric acid vapor over concentrated solutions of sulfuric acid at high temperatures. J. S. THOMAS AND W. E. BARKER. *J. Chem. Soc.* **127**, 2820 31(1925). This work is an extension of the measurements of Thomas and Ramsay (cf. *C. A.* **18**, 924) whose data were found to be uniformly low, probably because of adsorption of H_2SO_4 on the glass wool filter, and lack of thermal equil. The vapor pressures were detd. by the dynamical method with air, the partial pressure being calcd. by the formula $p = 760(r_1 + r_2)$, in which r is the vol. of the H_2O vapor or of the H_2SO_4 vapor, r_1 the vol. of air, and r_2 the combined vols. of the H_2O and H_2SO_4 vapors. The perfect gas law is assumed to hold. The satg. vessels were half filled with short pieces of small-bore tubing. The air was run through slowly to avoid mist, and the vapors were absorbed in NaOH followed by CaCl_2 . Solns. contg. 89.2% to 99.2% H_2SO_4 were studied at temps. ranging from 180 to 295°. The partial pressures can be represented by an equation of the form $\log p = \alpha - B/T - \gamma \log T$ for any given concn. The h. ps. obtained from the total pressure curves by extrapolation are considerably too high, but if it is assumed that complete dissociation of the H_2SO_4 vapor occurs, values are obtained agreeing within about 5%. The partial and total pressure isotherms have been constructed for 260°, 230° and 200°. The total pressures exhibit a sharp min. at 98.2% acid. The partial-pressure curves are in qual. agreement with the Duhem-Margules equation, but the quant. agreement is not close, probably because of the dissociation of the acid vapor.

A. W. KENNEY

Vapor pressure and heat of dilution of aqueous solutions. E. P. PERMAN AND TREVOR LOVETT. *Trans. Faraday Soc.* (advance proof), Jan. 10, 1926. —Vapor pressure of aq. urea solns. were measured by the method of Perman and Saunders (cf. *C. A.* **17**, 2528) and are tabulated for concns. up to satn. and temps. of 40°, 50°, 60°, 70° and 80°. The densities of these solns. are given for these conditions. $(\Delta H, \pi_0, \pi)/\alpha(n/N)$ holds pretty well where π_0 is the vapor pressure of H_2O and π is the no. of mols. of urea and N , no. of H_2O . There is evidently no hydration of the urea. Van Babo's law does not hold. The heats of diln. are given for the above conditions. P. and L. used a new *calorimeter* consisting of a Dewar flask, an elec. heating coil to compensate for radiation, and a second heating coil to bring back the original temp. of the flask. The heat of soln. = $E/RT/R$, where E is the p. d. across the coil and R its resistance. At lower temps. the affinity, A , is roughly proportional to the heat of diln., H , but at higher temps., A increases much more rapidly with increasing concn. than H and finally exceeds it. The values of H calcd. from Kirchhoff's equation agree well with the observed values. The soly. of urea at 50° was found to be 68.5 g. per 100 g. soln. as detd. from the intersection of the heat-of-soln. curve with the heat of diln. curve.

D. S. VILLARS

The relation of viscosity and vapor pressure of binary mixtures. N. A. YAINIK, M. D. BHALLA, R. C. TALWAR AND M. A. SOOFI. *Z. physik. Chem.* **118**, 305 17(1925). If the vapor pressure or the viscosities of 2 mixts. be detd. over an extended temp. range a series of temps. will be found at which the vapor pressure or (viscosity) will coincide. If these abs. temps. are represented by T and T_0 , then T/T_0 plotted against T_0 will give a straight line. Accepting the data of Zawidski for the vapor pressure of various mixts. of toluene and bromobenzene, toluene and iodobenzene, benzene and bromobenzene, benzene and ethylene dichloride, propylene dibromide and PrOH , MeOH and EtOH , pyridine and BuOH , pyridine and AcOH , chloroform and acetone, acetone and CCl_4 , CCl_4 and AcOH , CCl_4 and acetone, CCl_4 and EtH , EtH and AcOH , the authors have detd. the viscosities of these same solns. at different temps. between 15° and 80°. From these 2 sets of data discovered the following relationships between vapor pressure and viscosity of mixts. (1) When the vapor-pressure curve is a straight line the viscosity curve is also a straight line; (2) if the vapor-pressure curve passes through a min. the viscosity curve exhibits a max.; (3) if the vapor-pressure curve passes through a max. the viscosity curve shows a min. All formulas for detg. the viscosities of mixts. from the

viscosities of the components are of limited application, probably because they do not take cognizance of association, dissociation or change in vol. on mixing. E. R. S.

Molecular compounds of the phenols. V. Vapor-pressure curves. G. WEISSENBERGER AND F. SCHUSTER. *Monatsh.* **45**, 437-48 (1925); cf. *C. A.* **19**, 1702. —Where an equimol. complex has been inferred from the position of max. deviation of the vapor pressure-composition curve of mixts. of 2 substances, it is shown that the vapor pressure at a concn. c of 1 component should be given by $Pc/(c+1) + Pkc/(c+1)^2$, where k is a const. If the complex formed is of the type 1 mol. 2 mols. the second term of the expression becomes $Pkc/(c+1)^2$. These formulas are in satisfactory agreement with the observed figures for mixts. of cyclohexanol, *o*-, *m*- and *p*-cresols, 2-, 3- and 4-methylcyclohexanol with benzene, of cyclohexanol with EtOAc, and of *o*-, *m*- and *p*-cresols with EtO. But with mixts. of *o*-, *m*- and *p*-cresols with acetone or Et₂O, resp., second-order differences are found, which are represented with satisfactory accuracy by the addition of a further term $k'Pc^2/(c+1)^3$ to the above expression, and are interpreted as due to the formation of the 2 complexes 2 mol. 1 mol. and 1 mol. 1 mol. A similar second-order deviation occurring with mixts. of cyclohexanol with acetone and MeOH, resp., is attributed to association in one of the components. The values obtained for the system cyclohexanol-chloroform are too complex for interpretation. **VI. Behavior of the naphthols, the α -tetrahydronaphthols, and related substances.** G. WEISSENBERGER, F. SCHUSTER AND N. MAYER. *Ibid.* **49**, 55. —Measurements are recorded of the vapor pressure at 18° of solns. of various concns. of α -naphthol in MeOH, β -naphthol in acetone, α -tetrahydro- β -naphthol in EtOH and in acetone, tetrahydronaphthalene in EtOH, acetone, ether, benzene, and hexane, and CHCl₃, cyclohexanone in EtOH, acetone, benzene and CHCl₃, and of anethole in EtOH and CHCl₃, resp., the figures being compared in each case with those calcd. from the van't Hoff relation. The depression of vapor pressure caused by β -naphthol is less than that found with phenol, but the tetrahydro deriv. gives depressions of the same order as phenol. In the solns. of tetrahydronaphthalene, the observed vapor pressures are higher than the calcd. values in all cases with the exception of the solns. in CHCl₃, where expt. gives a lower value. Cyclohexanone causes a depression of vapor pressure only in the solns. in CHCl₃ where complex formation occurs, probably through the O atom of the keto group just as it occurs through the O atom of the phenols. Anethole, again, gives a depression of vapor pressure with CHCl₃ only. Surface tension and viscosity measurements are also recorded for these mixts. B. C. A.

Diffusion experiments in solutions. REINHOLD FURTH. *Physik. Z.* **26**, 719-22 (1925). —F. describes 2 microscopical methods for the study of diffusion phenomena. In the first method (for colored solns.) a square space of 1.2×1.2 cm., 1 mm. high, on a microscope slide with cover glass is bounded and divided into 2 halves (1.2×0.5 cm.) by vertical walls of hard rubber. In the left half through a slit in the long wall a thin sliding partition can be moved, which at first seps. H₂O from soln., in the right half a more dil. soln. of the same substance is placed. By comparing at different moments the color of the left and right fields through a slit diaphragm, perpendicular to the direction of diffusion, and movable parallel to this direction with an ocular micrometer, the progress of diffusion can be followed and measured. In the second method (for uncolored solns.), only one half of the instrument is used with a strongly magnifying objective. The measurements consist in focusing some fixed point on the bottom slide at different moments, reading the tube displacement and calcd. the concns. from the previously detd. n -concn. relationship. A series of detns. and curves on picric acid ($D = 6.5 \times 10^{-6}$), on Congo red ($D = 1.7 \times 10^{-6}$) and on sucrose are given, (where D is the coeff. of Fick's law, $dx/dt = D \cdot d^2c/dx^2$). The values, calcd. from $x^2 = tD(2\psi(1-2\psi))^2$, are valid when x is small relative to the total length of the vessel. Here t is time, x the velocity of diffusion, c the distance at which the const. concn. c is found at a time t , $v = c_0/c$

is diln., and the function ψ is the inverse of a function $\varphi(u) = 2\sqrt{\pi} \int_0^u e^{-y^2} dy$. The condition of this equation that x is proportional to \sqrt{t} for every v agrees well with the exptl. data at low x values. For the detn. of D only a few measurements are necessary. For sucrose (second method) the equation with const. D does not hold. It appears that D is a function of c ; for increasing c , D first falls to a min., then rises. The expts. are being continued. B. J. C. VAN DER HOEVEN

The kinetic theory of compressibility of solutions and binary fluid mixtures. II. K. C. KAR. *Physik. Z.* **26**, 737-9 (1925); cf. *C. A.* **19**, 3197. —The formulas derived for variation of compressibility with concn. agree with Gilbault's empirical formula (*Z. physik. Chem.* **24**, 385 (1897)). Observed and calcd. values for cane sugar, MgSO₄,

Na_2SO_4 , Li_2SO_4 , NH_4NO_3 , SrCl_2 and NaI are in close agreement. Compressibilities for any concn. k were obtained from the relation $\beta_k = I/(I + 2k)\beta_0$, where β_0 is the cubic compressibility of the soln. medium. The theoretical and exptl. curves of the immiscible mixt. CHCl_3 - CS_2 and the miscible mixt. H_2O - CH_3COOH are given, and their divergences discussed in light of the theory. H. R. MOORE

Assemblies of imperfect gases by the method of partition functions. R. H. FOWLER. *Proc. Cambridge Phil. Soc.* **22**, 861-85 (1925).—A discussion by use of partition coeffs. of the general theory of imperfect gases which has been developed with a view to a proper discussion of the equil. state of assemblies of ionized atoms at high temps. The subjects discussed are (1) gaseous assemblies surrounded by fields of forces of short range; (2) partition functions for the potential energy of the whole assembly; (3) further applications of $B(\vartheta)$; (4) dissociative equil. for mols. of finite extension; (5) effects of long-range forces; (6) a direct calcn. of the contributions of intermol. forces to the free energy. Under (5) the validity of the combined use of the equations of Boltzmann and Poisson are carefully examd., with particular reference to the theory of strong electrolytes advanced by Debye and Huckel. This theory can be regarded as established only for "small" values of the ionic concns. E. R. SCHIEFELZ

A property of van't Hoff's plane diagram. K. F. BELOGLAZOV. *Ann. Inst. Physico-Chem. Anal. Leningrad* **2**, 502-4 (1924).—It is shown that van't Hoff's diagram (*Vorlesungen über theor. u. phys. Chemie* **1**, 161) representing the isothermal crystn. of solns. of 2 salts may be adapted to crystn. at variable temp., the satn. isotherms for different temps. being brought into relation to 1 set of axes. Crystn. and the inverse process of dissolution correspond in the diagram with curves combining the isotherms for the initial and final temps. of the process. For such curves, in conformity with Kurnakov's terminology, the name "crystallization paths" is suggested. B. C. A.

The salting-out effect. The influence of electrolytes on the solubility of iodine in water. J. S. CARTER. *J. Chem. Soc.* **127**, 2861-6 (1925).—The effects of NaNO_3 and Na_2SO_4 at 25° and 35° and of NaH_2PO_4 and NaCl at 25° on the soly. of I_2 in H_2O have been detd. The solns. were made slightly acid to prevent the hydrolysis of I_2 . The soly. of I_2 in H_2O ($p_{\text{H}} = 5$) at 0° is 0.836 millimol./l.; at 25°, 1.321; at 35°, 1.808. The effect of salts may be expressed by the equation $\log S = \log S_0 - Kc$, where S is the soly. of I_2 in a salt soln. of concn. c , S_0 the soly. in H_2O . It is to be noted that the range of validity of this formula is much greater when the concns. are referred to a fixed wt. of H_2O rather than to a fixed vol. of soln.; hence they are expressed as mols. per 1000 mols. H_2O . The values of K are as follows: NaNO_3 at 25°, 0.00296, at 35° 0.00243, Na_2SO_4 at 25°, 0.0090, at 35° 0.0087; NaH_2PO_4 at 25°, 0.0062; NaCl at 25° 0.00575. The effect of HNO_3 and H_2SO_4 on the soly. of I_2 is of a wholly different character and follows no simple relation. With HNO_3 the soly. is considerably increased; it is slightly depressed by H_2SO_4 . A. W. KENNEY

The reaction of neutral water and of distilled water. I. M. KOLTHOFF. *Chem. Weekblad* **22**, 590-4 (1925).—The use of Me red as such leads to errors of 2 p_{H} units because of the effects of the acid character of the indicator in the unbuffered soln. Better results are obtained with neutralized Me red (NaOH) or of chlorophenol red (p_{H} of aerated water 5.9-6.0). A weakly alk. indicator like 2,4,6,2',4',2'',4''-heptamethoxytriphenylcarbinol is, however, the best. The Na salt of bromothymol blue may be used for neutral water; it gives a p_{H} of 6.7-6.6 for boiled water if CO_2 is excluded. The possible errors are discussed. B. J. C. VAN DER HOEVEN

The interpretation of the neutralization curves of mixtures of boric acid and polyhydric alcohols. I. M. KOLTHOFF. *Rec. trav. chim.* **44**, 975-82 (1925).—(In English.) Through the work of Magnanini and especially of Böeseken it has long been known that polyhydric alcs., through the formation of a complex, strongly increase the real acidity of a H_3BO_3 soln., but nothing is known quantitatively of the stability of these complexes. It is usually assumed that the stability of the complex formed is proportional to the increase of the real acidity of the H_3BO_3 soln., but results of Verkade (*C. A.* **19**, 1277) with meconic acid suggest caution in drawing this conclusion. From the neutralization curve of a mixt. of H_3BO_3 and a polyhydric alc. some idea of the stability and the dissociation const. of the complex can be obtained. In solns. which contain not more than 20% glycerol the complex const. K_{complex} is as follows: $K_{\text{complex}} = [\text{H}_3\text{BO}_3][\text{glycerol}]/[\text{H}_3\text{BO}_3 \text{ glycerol}] = \text{about } 0.9$, while the dissoc. const. of the complex acid is about 3×10^{-7} . Mannitol, fructose and probably also other polyhydric alcs. form multibasic complex acids in which 1 mol. of polyhydric alc. combines with more than 1 mol. of H_3BO_3 . The compn. of the complexes is dependent apparently on the ratio of H_3BO_3 to polyhydric alc. in the soln. F. J. WITZEMANN

Chemico-physical researches on acid phthalates of terpenic alcohols. V. PAOLINI.

Ann. chim. applicata **15**, 411-3(1925).—The dissocn. const. of acid phthalates of terpenic ales., which are useful compds. in the purification of terpenic ales. (cf. *C. A.* **5**, 3404; **14**, 2173), cannot be detd. by means of the elec. cond. of their solns. [Ostwald]. Neither can the const. be detd. indirectly from the hydrolysis of the Na salts, for the latter cannot be prepd. free of NaOH. Furthermore by mixing dil. aq. NaOH with excess of acid phthalate and filtering, the sol. Na salt cannot be sepd. from the insol. acid phthalate, because despite the insoly. of the latter in H_2O , it was found to be sol. in the corresponding Na salt soln. This latter property was, however, utilized to det. the const. of the acid phthalates by means of the relation: $\log 1/[H^+] = \log 1/K_a + \log S/A$, where $[H^+]$ is the H-ion concn. of the soln., K_a is the dissocn. const., S is the salt concn. and A is the concn. of free acid. A mixt. of dil. NaOH and excess acid phthalate when filtered gave a soln. contg. the Na phthalate of a concn. equal to that of the original NaOH, i. e., S . Titration of this soln. with N NaOH (phenolphthalein) and correction for the error due to the indicator (data obtained from Betti and Bonino to be published forthwith) gave A . $[H^+]$ was then detd. electrochemically, a quinhydrone electrode being used because of reduction of the compds. with a H electrode. K_a can then be calcd. by the equation above. Detns. at different concns. gave the following dissocn. const. (K_a) for 3 compds: 1- β -carbomenthol H phthalate 3.02×10^{-6} ; β -thujyl H phthalate 7.5×10^{-6} ; 1- α -terpineol H phthalate 1.42×10^{-5} .

C. C. DAVIS

The effect of iodine on the conductivity of aqueous solutions of cadmium iodide and potassium iodide. HEINRICH BRUNS. *Z. Physik* **34**, 751-65(1925).—The soly. of CdI_2 was measured over the temp. range from 0° to 85° . The conds. of CdI_2 and of KI were measured over the ranges 5–10% from 20° to 40° , and with added I_2 0–0.5%. The increase of cond. of CdI_2 solns. is due to the formation of complex ions. F. R. B.

The influence of hydrogen-ion concentration on the velocity of dialysis. HELMUT MOMMSEN. *Z. Physik. Chem.* **118**, 347-56(1925).—The change in velocity of dialysis through a parchment membrane brought about by changes of p_H of the liquid cannot be explained solely on the change of permeability of the membrane. The rate is the same for pure H_2O , 0.002 N NaOH and 0.002 N HCl. With urea and grape sugar only a slight increase was observed in acid soln. With electrolytes an increase of p_H increases the rate of dialysis of anions, a decrease in p_H accelerates the rate of cations. This phenomenon can best be explained by assuming that it is due to changes of the elec. charge of the membrane. The membranes used were S & S. 579 thinbles. An extended bibliography is given.

J. R. SCHIERZ

Investigation of the electrical behavior and the ion permeability of membranes. III. Potential of parchment membranes. A. FUJITA. *Biochem. Z.* **159**, 370-8 (1925); cf. *C. A.* **19**, 3274.—In a study of the diffusion of ions through parchment the change of p. d. across the membrane as diffusion occurs is followed. Then the diffusion potential of the same electrolytes is detd., and from these values the membrane potential is calcd. Salts, acids and bases are used. It seems that the mobility of the anions is lowered by the presence of the membrane. The membrane effect decreases with the valence of the cations, with the exception of the H ion. However, the effect of the multivalent anions upon the membrane potential is greater than that of the univalent anions. IV. Potential differences and permeability of collodion membranes. L. MICHAELIS AND A. FUJITA. *Ibid* **161**, 47-60.—The properties of an air-dried collodion membrane differ from an undried membrane in the following ways: it is only slightly permeable to H_2O and dissolved substances, as shown by its membrane potential, as well as by analysis of the solns. of salts used. It is especially impermeable to the OH ion. However, cations form a diffusion series in the same order as their mobilities in H_2O . In this behavior, collodion resembles apple peel, and also parchment, through which diffusion is much more rapid. Capillarity probably plays an important part in the diffusion process.

W. D. L.

Studies of electrical phenomena and ionic permeability of membranes. VII. Permeability of collodion membranes to multivalent cations. L. MICHAELIS AND AKIHI FUJITA. *Biochem. Z.* **164**, 23-30(1925).—The H ion is by far the most readily permeable ion; it is followed in order by Rb, K, Na and Li. With Li the limit is nearly reached where the permeability is still measurable. The collodion membrane is practically impermeable to all other ions: bi-, ter- and quadrivalent cations as well as all anions, even univalent. OH ions must also be included in this group though they are not perhaps as impermeable as other anions, but have a much smaller permeability than Li.

S. MORGULIS

The theory of chemical reaction velocity. II. NIELS BJERRUM. *Z. physik. Chem.* **118**, 251-4(1925); cf. *C. A.* **18**, 1418.—Mainly polemical against the second ar-

ticle of Brönsted (C A 19, 2901). The essential difference between their opinions is that B₁ defines chem reaction velocity as the no. of mols passing through a crit state X in the direction $A \rightarrow B$. This no. is according to B₁ larger for a reversible reaction near or in dynamic equil. than it is for an irreversible reaction, if both have the same initial velocity. Brönsted assumes an unchanging velocity.

B. J. C. VAN DER HOEFEN

Relation between rapidity of stirring and velocity of reaction in heterogeneous systems. (MILLER) A. KLEIN. *Roczniki Chem* 5 [1 3], 138-47(1925); cf. preceding abstr. — For reactions in heterogeneous systems the following equation is shown to hold. $(K-a)^n = \text{const}$, where K is the velocity of reaction with stirring, a the velocity without stirring, and n the no. of revolutions of the stirrer per min. The value of K also depends on the shape and exact position of the stirrer, and is not const. for the same app., but only for each expt. B C A

Reactions of benzoic acid at the boundary of two liquid phases. (MILLER) A. KLEIN. *Roczniki Chem* 5 [1 3], 101-9(1925). The mechanism of the reaction between benzoic acid dissolved in CCl_4 and aq. NaOH is shown to be in agreement with the diffusion theory. The velocity of the reaction is greatly accelerated by stirring and by rise in temp., 10° increasing the velocity by 32%. Benzoic acid in CCl_4 solns. of more than 0.01 N exists in the form of double mols. The partition coeff. of benzoic acid between the two solvents used is 0.00126. B C A

Relation between the temperature and velocity of transformation of metastable non-variant systems. N. I. STEPANOV. *Ann. Inst. Physico-Chem. Anal., Leningrad* 2, 500-2(1924). — Cases are considered in which the velocity of a transformation diminishes when the temp. is raised, use being made of the following equation for the abs. velocity of the transformation of metastable non-variant systems $V = Ka^n(T_0 - T)^n$, where T_0 is the abs. temp. of the equilibrated system, T the temp. at which the transformation occurs, n a positive no., a a no. greater than 1, and K a positive coeff. depending on the units in which V is measured. The significance of each term in this equation is discussed and also the different types possible for the curves representing the velocity. The considerations advanced are in agreement with the results of Cohen's work on the mutual transformations of gray and white Sn. B C A

Time rates of vaporization and chemical changes on surface of contact of two fluids. S. SANO. *Japan J. Phys.* 3, 117-31(1924). On the basis of several thermodynamical assumptions, S. obtains expressions for the rates of vaporization and the chem. reactions on the surface of sepn. of 2 fluids. B C A

Reactivity in the solid state between acidic and basic metal oxides. F. DE CARLI. *Atti accad. Lincei* [vi], 1, 533-7(1925); cf. Mazzetti and de Carli, C A 19, 1106. Heating curves were detd. for equimol. mixts. of basic and acidic oxides. For the mixt. $\text{MoO}_3\text{-BaO}$ reaction began at 290°, the temp. rising to 1200° in 25 sec., and a white friable mass resulting. The thermal effects in the following cases were much weaker and occurred at the temps. indicated: $\text{MoO}_3\text{-CaO}$ 650°, $\text{MoO}_3\text{-PbO}$ 650°, $\text{MoO}_3\text{-SnO}$ 400°, $\text{MoO}_3\text{-CdO}$ about 500°; $\text{MoO}_3\text{-NiO}$ about 495°, $\text{MoO}_3\text{-CoO}$ 410°; $\text{MoO}_3\text{-ZnO}$ 270° and a weaker effect at 720°; $\text{MoO}_3\text{-MgO}$ no reaction. $\text{WO}_3\text{-BaO}$ 190°; $\text{WO}_3\text{-CaO}$ 245°; $\text{WO}_3\text{-PbO}$ 210°; $\text{WO}_3\text{-SnO}$ 265°; $\text{WO}_3\text{-CdO}$ 250°; $\text{WO}_3\text{-NiO}$ 260°; $\text{WO}_3\text{-CoO}$ 255°; $\text{V}_2\text{O}_5\text{-BaO}$ 270°; $\text{V}_2\text{O}_5\text{-CaO}$ 630°; $\text{V}_2\text{O}_5\text{-PbO}$ about 560°; $\text{V}_2\text{O}_5\text{-CdO}$ 480°; $\text{V}_2\text{O}_5\text{-SnO}$ 250°; $\text{V}_2\text{O}_5\text{-ZnO}$ 260°; $\text{V}_2\text{O}_5\text{-MgO}$ 455°; $\text{Cr}_2\text{O}_3\text{-BaO}$ 220°; $\text{Cr}_2\text{O}_3\text{-CaO}$ about 550°. Sn dioxide, Bi_2O_3 , PbO and Al_2O_3 react only with BaO. B C A

The mechanism of reduction. V. H. J. PRINS. *Rec. trav. chim.* 44, 1050-5 (1925)(in English); cf. C A 20, 744. — The dissolution of Pb in a soln. of CH_3NO_2 in AcOH is much slower than in the presence of PhNO_2 . The reaction velocity measured is that of a true reaction velocity contrary to what was observed with PhNO_2 in which case a diffusion velocity was measured. The crit. concn. can be calcd. because the crit. velocity is a characteristic const. for Pb giving the max. amt. of Pb dissolved per min. in AcOH of a given concn. in the presence of a reducible compd. when the surface remains free from adsorbed Pb(OAc)_2 . The activity of the NO_2 group in PhNO_2 is about 65 times that of the NO_2 group in CH_3NO_2 . This difference must be attributed to the positively charged C atom of the C_6H_5 nucleus in accordance with the view of P. on the mechanism of substitution in the C_6H_5 nucleus. The reduction of the NO_2 group starts between the activated H atom of absorbed AcOH and probably the N atom of the NO_2 group. The activity of the latter depends on the magnitude of the positive charge of the N atom. In good agreement with this view is the fact that pos. groups show an increased reducibility if these are linked together in a mol. VI. *Ibid.* 1093-1100. — The influence of the surface conditions upon the velocity of reduction is discussed. Some methods of reduction are compared and the difference between these is expressed in terms

of the condition of the H used for the reduction. Three kinds of active H can be distinguished: (1) An activated H atom in an adsorbed mol. of acid; (2) activated H atoms formed from an adsorbed H^+ ion; (3) activated H in the form of negative H ions. The influence of the surface conditions of the metal is discussed in relation to the course of a reduction. A series of results on the reduction of Ph_2CO with various reducing agents under a variety of conditions is described and the mechanism of the formation of benzopinacol and benzohydrol is discussed in some detail.

E. J. WITZEMANN

Effect of diffusion on time rate of chemical change. S. SANO. *Japan. J. Phys.* **3**, 133-7(1924).—A theoretical discussion.

B. C. A.

Reactions between liquid amalgams and aqueous solutions. (MLLE). A. KLEIN. *Roczniki Chem.* **5** [1-3], 110-37(1925). The velocity of reaction of amalgams of Na and Zn with water, acids, alkalis and salts is investigated. The results obtained are not const. if with Na amalgam water, alk., or NaCl solns. are used; for other solns., the velocity falls with increase in the Na-ion concn. With neutral or alk. solns. a temp. rise of 10° increases the velocity by 46%, while the rate of stirring has no effect on the speed of reaction. The latter, for acid solns., consists of the sum of 2 components, one of which is the velocity of reaction in neutral soln., the other being at any moment proportional to the concn. of acid, to the rate of stirring, and to the temp. (a 10° rise increasing the coeff. of proportionality by 7%). but not to the concn. of amalgam. With Zn amalgam, the velocity of reaction with HCl appears to be proportional to the 4/6th power of the concn. of the latter, and is doubled by a 10° rise in temp. The presence of Zn ions in the supernatant liquid diminishes the velocity of reaction.

B. C. A.

Studies on atmospheric oxidation. II. The kinetics of the oxidation with sodium ferripyrophosphate. J. H. C. SMITH AND H. A. SPOEHR. *J. Am. Chem. Soc.* **48**, 107-12 (1925); cf. *C. A.* **18**, 2131. By studying the order of reaction and the amts. of O_2 absorbed in the oxidation of $KAsO_2$ and Na_2SO_3 by atm. O_2 with Na ferripyrophosphate as catalyst, the authors conclude that in both cases the active oxidizing agent is an intermediate "mol. oxide" (of the type $FeO \cdot O_2$) which is formed. In the case of Na_2SO_3 , however, the assumption that the Fe salt oscillates between its 2 valences is not impossible.

R. E. GIBSON

Contribution to knowledge of reduction-oxidation and autoxidation processes. WILHELM TRAUBE AND WILLI LANGE. *Ber.* **58B**, 2773-90(1925). Chromous salts in alk. aq. soln. are oxidized with liberation of H_2 on addn. of metals of Pt group, either in colloidal form or as salts. If org. materials are mixed with the chromous soln. and the Pt metal, and the soln. is then made alk., they are powerfully reduced, e. g., H_2CN to $MeNH_2$, CH_2ClCO_2H to $AcOH$. Ferrous hydroxide and carbonate slowly reduce water at 100° in alk. soln. with addn. of Pd salts, although manganous and stannous salts give negative results under the same conditions. The reaction is so slow that its velocity may be limited to the rate at which the Pd loses H_2 with the steam and takes it up again from the water. CO reacts with water in the presence of H_2 satd. Pd to form CO_2 , the H_2 content of the Pd increasing. Formic acid is stable in the presence of colloidal Pd, so cannot be the intermediate product. Alkali accelerates the reaction, but it may occur in the vapor phase at the surface of Pd. The mechanism in the presence of free O_2 is probably different in all these cases. The autoxidation of mixts. of glycerol or mannitol with solns. of CuO in aliphatic amines or amino acids gives principally formates.

B. H. CARROLL

The relation of homogeneous to catalyzed reactions. The catalytic decomposition of hydrogen iodide on the surface of platinum. C. N. HINSHELWOOD AND R. E. BURK. *J. Chem. Soc.* **127**, 2896-2900(1925); cf. *C. A.* **19**, 1805, 3198. — The rate of decompn. of HI was followed by the decrease in pressure. Catalysis was effected by a heated Pt wire in a reaction vessel kept in ice. That the action was truly catalytic was shown by the fact that the theoretical change in pressure was observed after complete decompn., and by the fact that the resistance of the wire remained unchanged. The effects of temp. and pressure on the reaction rate were studied and in all cases it appears that the reaction is a simple monomol. one, corresponding to the reaction $HI = H + I$.

A. W. K.

The catalytic hydrogenation of organic substances. OTTO SCHMIDT. *Z. physik. Chem.* **118**, 193-239(1925). Hydrogenation catalysts are generally metals, situated in the minima of atom or ion vol. curves. The absorption of H_2 by them follows a $\sqrt{p_{H_2}}$ relation, i. e., absorption as atoms or as ions. From calorific data the first possibility can be practically discarded. Ionization of H_2 in the metal is the more probable because the work necessary for it is negligible by virtue of the extremely high "dielec. const." of the metal. The smaller the metal ion is, the easier ionization will take place. The primary reaction is $H_2 \rightarrow H_2^+ + e^-$; the second step is uncertain. Using Bohr's original H_2 model, S. calculates roughly at what distance r from the metal ion nucleus an

electron must come to be attracted sufficiently so that ionization of the H_2 mol. can follow. He finds a limiting r for univalent metals of 0.49×10^{-8} cm., for bivalent 0.70×10^{-8} cm., etc. From estns. by Grimm (*C. A.* 15, 3921) of ion diams. the radii of $Ni^{++} < Co^{++} < Fe^{++}$ and $Zn^{++} < Cu^{++}$ fall below these limits. Ag^+ , Au^+ and Pb^{++} are too large, and no data are available for Pt metals. These theoretical predictions are well borne out by the facts; e. g., pure O-free Zn is a more powerful catalyst than Cu. Expts. on powdered Fe, Co, Ni, Cu, Ag, Au, Zn and Pb as catalyzers for the $C_2H_4 + H_2 \rightarrow C_2H_6$ reaction are given in detail. At higher temps. the activity increases as is generally to be expected from the $e^{-\theta/RT}$ proportionality of the degree of ionization; also the H_2 mol. probably then can approach the metal nucleus more closely. The actual hydrogenation process takes place in the metal between dissolved ionized H_2 and dissolved C_2H_4 . Presence of metal oxides is unessential; it sometimes even prevents hydrogenation; presence of small amts. of a second metal (V, Cr, Mo, W, U, Mn) may promote the reaction considerably by preventing the sintering of the metal surface. In the second part of his paper S. gives the results of expts. on the surface and hydrogen absorption of Ni powders. The surface was estd. by dissolving the powder in dil. (2.5%) HCl and weighing before and after a short interval (11 sec.). The decrease in wt. can be taken as proportional to the surface. From expts. of homogeneous Ni powders (Schoop process) and Ni plates the velocity of attack was found to be 1.6×10^{-7} g. Ni/sq. cm. per sec. The surface of a Ni powder depends on the temp. of reduction of $NiCO_3$. At 300° a much more active powder can be obtained than at 500° , while at 800° it is entirely inactive. The mean surface per g. Ni was detd. as 10^6 sq. cm. No difference in lattice structure between the 350° and 600° catalysts was found. In the absorption expts. only part of the H_2 could be pumped off; this part followed a $\sqrt{p_{H_2}}$ law; at higher temps. more H_2 can be recovered. For strongly sintered powders the H absorption diminishes when the temp. rises; this agrees with the exothermic character of the process (+ 11.4 cal. according to Foresti). If P represents mg. H taken up per g. of Ni and O the surface per g. of the powder the quotient P/O at 20° and 760 mm. pressure is of the order 10^{-5} . This means that at low temps., when the H cannot be pumped off, the gas is held near to the Ni surface by loose bonds, probably as negative ions.

B. J. C. VAN DER HOEVEN

Actions in the presence of carbon. C. SANDONNINI. *Atti accad. Lincei* [6], 2, 427-32 (1925).—The use of substances to render reactions sensitive to light that are not so otherwise has led to many interesting results. Recently Rosenmund, *et al.* (*C. A.* 17, 3837) and Piccard (*Helv. Chim. Acta* 5, 117 (1922)) developed some addnl. data. S. has studied the catalytic action of powdered C and since it is a good absorber of many kinds of radiation wished to det. its influence on processes sensitive to light. The C used was especially prepd. as described and contained only traces of SiO_2 . The $(CO_2H)_2$ soln. of known titer was boiled under a reflux condenser in transparent quartz. The illumination came from an arc lamp 15 cm. from the flask. After illuminating 3 hrs. the $(CO_2H)_2$ solns. were unchanged. The addn. of C was without effect. When 0.01 g. uranyl sulfate (I) was added to 100 cc. $(CO_2H)_2$ soln. 10-12% was decompd. in 3 hrs. I + C gave a decompn. of only 6-7%. 25 cc. of 1% p - $BrC_6H_4SO_3K$ (II) + 25 cc. 20% KOH + 5 drops 5% $CuSO_4$ illuminated while boiling gave results different from those obtained by R. *et al.* (*l. c.*). A series of expts. in the dark and the light was carried out. Without any catalyst a trace of KBr was formed in the dark and 1.5-2.0% II was decompd. in the light. With 0.20-0.05 g. C 0.85-0.65% II was decompd. to give KBr in the dark and 2.75-2.3% in the light. With 0.0012-0.0003 g. Cu 3.8-4.2% II was decompd. in the dark and 7.8-6.5% in the light. With both Cu and C 23.7-10.7% II was decompd. in the dark and 26.3-14.3% in the light. The results show that the action of C alone is quite weak, that Cu acts as R. *et al.* observed and that C + Cu are strikingly active even in the dark. The action of C is thought to be due to its dispersive action on the Cu by which its active surface is increased. Expts. with other more active samples of Cu prepd. according to P. (*l. c.*) and R. *et al.* (*l. c.*) support this suggestion.

E. J. WITZEMANN

Varieties of thorium oxide and their catalytic action in the dehydration of alcohol. G. R. LEVI. *Atti accad. Lincei* [6], 2, 419-22 (1925).—The oxide acts as an energetic catalyst in the formation of C_2H_4 from EtOH (Sabatier and Mailhe, *C. A.* 4, 2633). L. wished to examine the varieties of Th oxide in relation to their structure and their catalytic power. Seven varieties of Th oxide were prepd. For *a*, *b* and *c*, $Th(SO_4)_2$ was pptd. with NH_4OH and after prolonged washing dried at room temp., at 80° and at 120° , resp.; *d* was the oxide prepd. from *a* dried at 340° ; *e* was the oxide obtained from *a* at 1050° ; *f* was the meta-oxide obtained from oxalate by heating at 750° ; *g* was the meta-oxide obtained from the nitrate by heating at 750° . *a*, *b*, *c* and *d* were all amor-

phous while e , f and g were cryst. as shown by their photograms. In the tests on the formation of C_2H_4 by the use of these preps. no appreciable differences could be detected in their catalytic action. The amorphous preps. showed no tendency to become cryst. by heating at 340° with EtOH vapor. I. J. WITZEMANN

The catalytic phenomena which accompany the solution of zinc in acids. M. TZENTNERSHVER and M. STRAUMANIS. *Z. physik. Chem.* **118**, 415-37(1925).—T. and S. detd. the velocity of soln. of Zn in 0.5 N HCl and 0.5 N H_2SO_4 to which had been added varying amts. of salts as catalysts. The plate of Zn (av. diam. 1.2 cm) was immersed in the acid, while the soln. was being stirred (117 r. p. m) the H_2 escaping was collected and measured. The velocity const. was calcd from the formula $K = [(11206 \times 2.303V)/F(t_n - t_0)] \times \log_{10} [(11206 C_0 V - v_0)/(11206 C_0 V - v_n)]$ in which F = area of Zn, t_n = elapsed time, t_0 = length of induction period (time elapsed before all catalyst has been pptd.), C_0 = concn. of acid at beginning in ϵ . equiv./cc., V_n vol. of gas evolved to t_n , v_0 = vol. evolved during induction period. K is dependent upon the character of the ppt., the area of the Zn, the amt. of catalyst, the speed of stirring. Even in parallel detns. it may vary as much as 20%. In 0.001 M concns. the salts of Fe, Ag, Sb, Bi, Cu, As, Co, Au, Ni, Pt increase the velocity of soln. of Zn in the order given. Cd forms a cryst. ppt. but prevents soln., Tl reacts similarly, Pb forms a smooth coating which prevents action of the acid, Sn and Hg are also without positive action. Certain oxidizing salts ($KMnO_4$, $Na_2Cr_2O_7$, $(NH_4)_2MoO_4$, $(NH_4)_2WO_4$) have an accelerating effect in proportion to their oxidizing power. The oxides of the metals of the acid radical act as the catalysts. The effect of overvoltage is discussed in another paper (cf. following abstr.). E. R. SCHIERZ

The overvoltage of hydrogen on finely divided metals and its relation to the catalytic action of metals on the solution of zinc. M. TZENTNERSHVER and M. STRAUMANIS. *Z. physik. Chem.* **118**, 438-46(1925).—The overvoltages of finely divided Zn, Tl, Sn, Pb, Bi, Cd, As, Cr, Cu, Au, Sb, Ni, Ag, Co, Fe, Pt, which varied from 0.78 to 0.005 v. (Pt), in the presence of a vigorous evolution of H_2 were measured but showed no relation to the velocity consts for H_2 evolution (cf. preceding abstr.). The smoother the deposit of the metal the higher the overvoltage. H_2 possesses a definite min. overvoltage for each c. d. characteristic for each metal. With Zn and Bi the overvoltage decreases with decrease in concn. of electrolyte. From this investigation C. and M. conclude that the theory of Ericson-Aurén and Palmar does not explain the phenomena accompanying the soln. of Zn. E. R. SCHIERZ

Autocatalyses with variant catalysts. Febrile biperiodic reactions. A. QUARTAROLI. *Gazz. chim. ital.* **55**, 619-38(1925).—In speaking of autocatalyses with variant catalysts Q means variant not only as to quantity but also quality and thus efficiency. In the previous paper (C. A. **19**, 1524) the case of the formation, in the course of the reaction, of a catalyst that varies not only in quantity (it accumulates for a time) as in the case of ordinary autocatalysts, but undergoes changes with the diminution of the concn. of the reacting substance (H_2O_2), was described. Most of the reactions of metallic oxides with H_2O_2 represent ordinary autocatalytic processes. The behavior of Cu was strange. $Cu(OH)_2$ decomps. an alk. soln. of 3-1% H_2O_2 slowly and then 1% solns. tumultuously, giving in the first case a black ppt. and in the second case a green one. These expts. have been extended and the detailed results are given in tables and graphs. In the case of Cu and Tl there are evidently 2 febrile periods with a period of min. intensity between. This effect appears to be due to the successive formation of different catalysts depending on varying conditions of concn. of H_2O_2 in the course of the reaction. This is made evident in the case of Cu by the changes in the color of the ppt. (brown-black, dark green, apple-green, blue-green). It is thought that a black peroxide is 1st formed and that later when the diln. of H_2O_2 has become sufficient a green suboxide of great activity is formed to which the 2nd most intense period is due. In fact Cr, Mn, Fe, Co and Ni form peroxides with H_2O_2 in alk. soln. but there is doubt about the formulas for these peroxides because they are difficult to isolate from the system in which they are formed without alteration. Ag, Au and Hg oxides are reduced in alk. soln. but it is undecided whether the metals or the suboxides are the intermediate products. Cu occupies an intermediate position between these 2 groups. The weakly active Cu peroxide formed at a concn. of 1.5% H_2O_2 has an activity that agrees well with the succession $Co < Ni < Cu$. The time necessary for 1 mg. of these oxides to decompose $1/2$ of the H_2O_2 in a 3% soln. is a few mins. with Co, 100 mins. with Ni and 200 mins. with Cu at 45° . On the contrary the action of the active green suboxide of Cu corresponds to that of the suboxides of Ag and Au. All the above relates only to solns. contg. 1.66% NaOH. The 3 phases of action of Cu are summarized thus: (1) The little intense febrile period of slow formation and accumulation of the peroxide to a max. of concn. and then the

beginning of the reduction of this to normal oxide, (2) the period of stagnation with max. accumulation of normal oxide; (3) the intense febrile period with reduction of normal oxide to suboxide and accumulation of this nearly to the end. In this way the zone of concn. of H_2O_2 in which it passes from an oxidizing action to a reducing action is quite restricted in solns. which are already quite dil. The position of this zone is changed by changes in the alky. On diminishing the alkalinity this zone is moved toward lower concns. of H_2O_2 . In the case of Ag and especially with Au and Hg nothing occurs in alk. H_2O_2 soln. except reduction, which increases with the alkalinity. With Pb, which is more oxidizable than Ag, Au and Hg, if the alky. and, consequently, the reducing action are weak a very active peroxide is formed, if the alky. is stronger there is a period of intense febrile action after which when the ratio between H_2O and NaOH falls, a lower less active oxide (PbO or $Pb(ONa)_2$) is formed. With Tl the catalytic action is due to peroxides above Tl_2O and to special labile oxides between Tl_2O and Tl_2O_3 and the transformation of the 1st into the 2nd through the inactive Tl_2O_3 explains the 2 periods for Tl. Small changes in concn. affect these processes greatly. Thus with 1 mg. CuO in 1.66% NaOH the velocity of decompn. of H_2O_2 on passing from 1.25% H_2O_2 to 0.75% becomes 20-30 times greater. The effect of uniting 2 catalysts ($Cu + Pb$) is considered in detail.

E. J. WITZEMANN

Graphic methods of representing equilibria in systems of three components. G. G. URAZOV. *Ann. Inst. Physico-Chem. Anal. Leningrad* **2**, 482-3 (1924). U. develops methods for the graphic analysis of the equil. in systems of 3 components characterized by the existence either of a stable chem. compd. or of a compd. melting with decompn., the formation of solid solns. between the components being excluded in both cases. Application of the method of "crystallization paths" permits of the detn. of the compn. of any point within the projected triangular system, and of the order in which solid phases are deposited; it is also possible to foretell the no. of breaks in the cooling curve for a mixt. of any compn.

B. C. A.

Equilibrium diagram of ferrous oxide and silica. O. VON KELL AND A. DAMMANN. *Stahl u. Eisen* **45**, 890 (1925). The equil. diagram for $FeO-SiO_2$ mixts. shows 2 eutectic points (1115° and 1075° at about 40% and 1% SiO_2 , resp.), and a max. at 1503° with 30% SiO_2 in the mixt. corresponding to the compd. $2FeO \cdot SiO_2$. With more than 45% SiO_2 present, the m. p. is too high to be detd. accurately.

B. C. A.

The fusion curves of the systems, benzene *m*-xylene, toluene *m*-xylene and *m*-xylene-*p*-xylene. AKIRA NAKATSUCHI. *J. Soc. Chem. Ind. Japan* **29**, 31 (1926).—The f. ps. of the solns. of various components of the systems, C_6H_6 -*m*- C_6H_4Me , C_6H_5Me -*m*- $C_6H_4Me_2$ and *m*- C_6H_4Me -*p*- C_6H_4Me were measured and the fusion curves of the systems were drawn. The f. ps. of these components are 5.6° for C_6H_6 , 95.7° for C_6H_5Me , 50.5° for *m*- C_6H_4Me and 13.15° for *p*- $C_6H_4Me_2$. The heats of fusion of the components calcd. from the data obtained were 1150 cal. for C_6H_6 and 2400 cal. for *m*- $C_6H_4Me_2$.

K. K.

The fusion curves and some physical properties of the system, benzene toluene. SHINROKU MITSUKURI AND AKIRA NAKATSUCHI. *J. Soc. Chem. Ind. Japan* **29**, 25.9 (1926).—The f. ps. of the solns. of various compn. of C_6H_6 and C_7H_8 have been measured and the fusion curves of the system were obtained. The f. ps. of both components are 5.56° for C_6H_6 and 95.7° for C_7H_8 , and the eutectic point is at -103° and 85% of C_7H_8 . The heats of fusion of the components are calcd. from these data by the thermodynamical formula: 2490 cal. for C_6H_6 and 1100 cal. for C_7H_8 at their m. p. The sp. gr. and the refractive indexes of the system have been detd. at 20° . As an application, the compns. of fractions of the distillate from a light oil were detd. by the measurement of their f. ps.

K. K.

Equilibrium in the system methyl acetate-water-methanol-acetic acid. G. J. BURROWS. *J. Chem. Soc.* **127**, 2723-8 (1925). The equil. const. (K) of the above reaction is studied in solns. contg. relatively small amts. of H_2O and definite quantities of HCl. The effects of dilg. the system with H_2O , MeOH and an indifferent solvent like acetone are also recorded. K depends not only on $[H_2O]/[HCl]$ but also on the amts. of MeOH and acetone in the reaction mixt., being diminished if any one of these factors is increased. HCl displaces the equil. in virtue of its effect on the activity of the H_2O present. By taking this into account B. obtains a const. value of 7.0 for K in reaction mixts. in which $[HCl]$ varies considerably. Copious numerical data are given.

R. E. GIBSON

Equilibria in systems with phases separated by a semipermeable membrane. XI. Systems in which a substance other than water diffuses through the membrane. F. A. H. SCHREINEMAKERS. *Verslag Akad. Wetenschappen Amsterdam* **34**, 675-84 (1925).—

A continuation along the same lines of previous papers (cf. *C. A.* **20**, 137). Also in *Proc. Acad. Sci. Amsterdam* **28**, 812 (1925). B. J. C. VAN DER HOEVEN

The influence of pressure on the equilibrium of binary systems. I. N. A. PUSHIN AND J. V. GREBENSHCHIKOV. *Z. physik. Chem.* **118**, 276-94 (1925). The eutectic point of a binary mixt. ($A + B$) under high pressure tends to shift in the direction of the component B which has the smaller dt/dp deriv. It is thus possible to come from the soly. curve of B by an increase of the pressure via the eutectic to the soly. curve of A . The soly. curves of 1 substance at higher pressures will become less and less parallel. Exptly., these predictions were verified by detns. of t , p and c for a eutectic mixt. and soly. curves (pyrometric method, cf. *C. A.* **19**, 2158). Diphenylamine, urethan and nitroanisole, resp., have the following values of dt/dp , 0.0277, 0.0215, 0.0103; 0.0051, 0.0234-0.0195 for 1 and 2000 atm. The equil. of the system, 85 mol. % urethan-15 mol. % diphenylamine was examd. at the eutectic point. The eutectic point 32.2°, 1 atm., 39 mol. % diphenylamine shifts continuously to about 51.6°, 17.5 mol. % for 1550 atm. For urethan- p -nitroanisole mixts. the eutectic goes from 31.2°, 36.5 mol. % p -nitroanisole at 1 atm. to about 53.29 mol. % at 2550 atm. Some expts. are given on the Na-Hg system; no evidence for the above given rules is, however, obtained because the dt/dp values of the components differ only slightly. B. J. C. VAN DER HOEVEN

Reduction equilibria of zinc oxide and carbon monoxide. C. G. MAIER AND O. C. RALSTON. *J. Am. Chem. Soc.* **48**, 361-71 (1926). The equil. data for the reaction $\text{ZnO}(s) + \text{CO} = \text{Zn}(g) + \text{CO}_2$ are detd. in the range 500-580°, by passing the equil. gases through molten Pb, or better Sn, at the same temp. to dissolve out the Zn, the gases being subsequently analyzed for CO and CO_2 . The standard free energy equation for the reaction is $\Delta F^\circ_T = 17,290 + 4.46 T \ln T - 1.56 \times 10^{-4} T^2 - 3.715 \times 10^7 T^{-3} - 59,7037$. $\Delta F^\circ_{298} = +36,920$. The present data give 85,830 as the heat of formation of zinc oxide, which is in accord with 83,097 found by recalcn. of older detns. The entropy, S°_{298} for ZnO is 10.20 entropy units. Carbon forms during detns., $2\text{CO} = \text{C} + \text{CO}_2$, as a result of the catalytic effect of the zinc surface. A. T. F.

Thermal behavior of hydrated barium aluminate. G. MALQUORI. *Atti accad. Lincei* [vi], **1**, 115-8 (1925). $\text{BaAl}_2\text{O}_4 \cdot 5\text{H}_2\text{O}$, prepd. by boiling pptd. alumina with satd. $\text{Ba}(\text{OH})_2$ soln. in absence of CO_2 , loses 3 mols. of water at 190°, becomes anhyd. at 310°, and exhibits 2 arrests in the heating curve, at 725° and 1010°, resp., corresponding with 2 stages in the decompn. of the compd. B. C. A.

Nature of aluminium-magnesium alloys. G. G. URAZOV. *Ann. Inst. Physico-Chem. Acad. Leningrad* **2**, 180-1 (1924). Investigation of the m-p diagram and microstructure of alloys of Mg with Al shows that these 2 metals form 3 series of solid solns. In the first Al dissolves up to 11 at. % Mg, in the second Mg dissolved up to 7 at. % Al, while the third contains between 37 and 59 at. % Mg. The m-p diagram consists of 3 branches, corresponding with the temps. at which the first crystals of the 3 series of solid solns. appear. B. C. A.

The proposition of establishing a second thermochemical standard. (Reply to M. W. Swientoslawski.) P. E. VERKADE AND J. COOPS, JR. *Bull. soc. chim.* **37**, 1536-10 (1925); cf. *C. A.* **20**, 326. Polymethyl Salicylic acid is recommended as a suitable thermochem. substance. F. C. KRACEK

Thermal conductivity of wires and rods. T. BARRATT AND R. M. WINTER. *Ann. Physik* [iv], **77**, 1-15 (1925). The expression $K = H^2 / pqhV^2 \cot^2 \alpha l$ gives the cond. of a wire or thin rod, and is simplified to $K = H^2 / pqhV^2$ when the length l is great (K is the thermal cond. of the wire, p the circumference of the rod, q the cross-sectional area, h the emissivity of the surface, V the temp. of the hot end, and $\alpha = \sqrt{hp/qk}$. Of these quantities, h is the most difficult to measure. Accordingly, the exptl. methods are designed to secure accurate values for H (the heat supplied in calories per sec. to the hot end of the wire) and V , and the theoretical treatment is designed so that h may be eliminated entirely from the calcs. The technic is based on earlier work (*C. A.* **9**, 2345). Values of K are given for Pt, Ir, Rh, Au, Ta, Mo, various alloys, and for glass, ebonite, graphite and various woods. The mathematical treatment includes a solution of the equation for the fall of temp. along a rod enabling K to be evaluated from H , V , q , and the temp. at any point along the rod. Various cases are discussed and simple formulas deduced so that the result of the work is to place on a sound theoretical basis the exptl. methods developed by the authors for the measurement of K , using very small samples of material. B. C. A.

Black body for optical pyrometer calibration. H. S. ROBERTS. *J. Optical Soc. Am.* **10**, 723-4 (1925).—Details are given for the construction of a black body for use in the calibration of optical pyrometers from the fusion point of a metal. A small piece

of the metal is heated to fusion at the bottom of a graphite or porcelain tube of suitable shape, and the "matching" is done as the metal is observed to melt. The advantages of the procedure are that it gives a direct detn. of the temp. of the black body and that very little of the standard metal is required.

B. C. A.

Latent heat determinations. A. W. SMITH. *J. Optical Soc. Am.* **10**, 711-22 (1925).—A summary of the methods proposed for detns. of the latent heats of fusion and evapn.

B. C. A.

Heats of solution and heats of incomplete reactions. (MLE.) BÉRINGER AND A. TIAN. *Compt. rend.* **180**, 1907-10 (1925).—If a chem. reaction occurs in the presence of a solvent the heat effect is given by $X = Q + Q_1 - Q_2$, where Q is the heat released in the thermochem. expt. Q_1 is the heat of soln. of reactants (1), and Q_2 the heat of soln. of resultants (2), and X is the required heat of reaction. For completed reactions Q_1 and Q_2 are easily measured. They are also measurable for incomplete reactions which can be studied calorimetrically in dil. solns., for Q_1 and Q_2 are given by the algebraic sum of the heats of soln. of all the components of (1) and (2) in a large vol. of solvent S . The problem is quite different if the reaction has to be carried out in concd. solns. Many org. reactions, e. g., esterification, can only be carried out slowly in concd. solutions, and are incomplete. While the equation is still theoretically valid, practically the measurement of Q_1 and Q_2 is possible only when the reaction is either (a) purely catalytic and the catalyst is not in concd. soln., or (b) the reaction is very slow. Methods are indicated whereby approx. values for Q_1 and Q_2 can be obtained under these conditions.

B. C. A.

The heat of combustion of salicylic acid. LÉNDRE BERNER. *J. Chem. Soc.* **127**, 2747-50 (1925).—The heat of combustion of carefully purified salicylic acid is $5233.8 \pm 0.515^\circ$ cal. per g. at const. vol. Wts. are referred to vacuum and the instrument is calibrated with benzoic acid (6324 cal. per g.). Modern procedure is used. Salicylic acid is suitable as a secondary standard for calorimetry.

F. R. B.

Nature of chemical combination—structure of silicon tetrachloride. GEORG JOOS. *Physik. Z.* **26**, 734-7 (1925).—Theoretical deductions of the energy liberated in the binding of Cl^- by Si^{++} . By assuming a mol. of tetrahedral symmetry with each Cl sepd. 2.59 Å U., the energy set free is 2847 and 2301 cal./mol. from electrostatic and thermochem. calcs., resp. The electrostatic value was calcd. by taking into account the magnitude of orbital deformation, as developed by Fajans and J. (*C. A.* **18**, 2103) Fowler's spectroscopic measurements (*C. A.* **19**, 1818) are used to calc. the J values (ionization work). For Si , Si^+ , Si^{++} , Si^{+++} , Si^{++++} the values obtained are in good agreement with F.'s data.

H. R. MOORE

Heats of adsorption and surface tension at the boundary. H. CASSEL. *Physik. Z.* **26**, 862-4 (1925).—A thermodynamical criticism of the work of Iliin (cf. *C. A.* **20**, 135) on the relationship between heats of adsorption and surface tension lowering by adsorption.

F. C. KRACEK

Analogy and difference in the behavior of various forms of energy in reversible and irreversible transformations. E. DENINA. *Gazz. chim. ital.* **55**, 638-45 (1925).—A thermodynamical paper.

E. J. WITZEMANN

Evaluation of the grating energy of crystals. W. WESSEL. *Z. Physik* **30**, 217-24 (1924).—Analysis after the classical fashion of the thermal equil. between the vapors of a salt and its ionized radicals shows that the grating energy of the salt can be detd. from known data and partial pressures of the ions present. The chem. const. involved are calcd. by the method of Born and Heisenberg (*C. A.* **18**, 2837). Direct measurements of the partial pressures of ions are wanting; they are projected by W.

B. C. A.

Electrochemistry of non-aqueous solutions. VI. Electrodeposition of some metals from anhydrous solutions in amyl alcohol, acetonitrile, aniline and quinoline. R. MÜLLER, E. PINTER AND K. PRETT. *Monatsh.* **45**, 525-34 (1925); cf. *C. A.* **18**, 1229. Electrolysis of solns. of Li nitrate or MgBr_2 in acetonitrile and of $\text{Ca}(\text{NO}_3)_2$ in Am alc. with Hg or Pt cathode did not yield the resp. metals, decompn. occurring at voltages below those found for the metal against such solns. On the other hand, cryst. Ag was deposited when solns. of AgNO_3 in Am alc., acetonitrile, quinoline, or aniline were electrolyzed, the potential differences being const. and easily reproducible, so that the reversibility of the Ag electrode is proved with these solvents. Values of the potential differences for various c. ds. in each case are tabulated and represented graphically. The decompn. potential of AgNO_3 is 1.0 v. in Am alc., 1.15 v. in acetonitrile, 2.15 v. in quinoline and 0.5 v. in aniline soln.

B. C. A.

The influence of an electrostatic charge on the surface-conductivity of a rock-salt crystal. P. VAILLANT. *Compt. rend.* **181**, 915-7 (1925).—A salt crystal is embedded

in a mica and in touch with Sn electrodes in such a way that it can be charged up to 92 v. on one side. The other pole of the battery is earth-connected. The current produced on the other side by a 74-v. battery across a 1-mm. slit between the electrodes is measured by a galvanometer in microamp. The current through the body of the crystal is negligible. At 25° over dil. H_2SO_4 the current is increased 1.08 times by a pos. charge and decreased 0.91 times by a neg. charge.

JOHN T. STERN

The electrical conductivity of some silver-zinc alloys in quenched condition. G. J. PETRENKO. *Z. anorg. allgem. Chem.* **149**, 395–400(1925).—Careful cond. detns. at 25° and 100° confirm the existence of a compd. ZnAg , stable up to the m. p., 694°, which was assumed previously on thermochem. evidence.

JOHN T. STERN

Electromotive behavior of cupric oxide. R. E. W. MADDISON. *Trans. Faraday Soc.* **1926** (advance proof).—In the cell $\text{Pt} | \text{CuO}, \text{Cu}_2\text{O}, N \text{ NaOH} | N \text{ NaOH HgO} | \text{Hg}$, the CuO , Cu_2O electrodes initially have a relatively high potential; this drops some 40 milliv. to different values after several weeks. A bibliography is given. The temp. of prepn. of CuO influences the initial and final p. ds. of the electrodes. O_2 occluded on the electrode does not seem to be the cause of variation in the results. It has not been possible to conclude definitely for or against the polymerization hypothesis of Allmand (cf. *C. A.* **4**, 1947).

D. S. VILLARS

Electrode capacity and resistance of electrolytes for a wide range of frequencies. B. B. BANERJI. *Trans. Faraday Soc.* **1926** (advance proof).—Polarization capacity at an electrode varies with the frequency according to the formula, $y = (\alpha + \beta x)/(x + \gamma)$, where x is $(\text{frequency})^2 - 10^6$ and y is capacity in microfarads. The consts. α , β and γ are, resp., 12.8, 0.71, 0.63 for Ag electrodes in AgNO_3 (10 g./100 cc. at 18°); 35.9, 0.716, 0.541 for Cd in CdSO_4 (15 g./100 cc. at 19°); and 13.7, 2.85, 2.2 for Ni in 2 N NiSO_4 . These results can be explained mathematically as being due to 2 condensers in series, one of them leaky; the latter is due to the double layer and the other that caused by concn. changes brought about by the transport phenomena. From the above consts. are calcd. the capacities and resistances of the leaky condensers and the true cond. of the above solns. are found to be 0.0436, 0.036, 0.042 mhos, resp.

D. S. VILLARS

Contact rectification by metallic germanium. ERNEST MERRITT. *Proc. Nat. Acad. Sci.* **11**, 743–8(1925).—A systematic investigation of the current-voltage sensitivity of Ge with contacts made by pressing various metal surfaces against the Ge specimens. Fe and Al give almost identical curves when “Ge to contact e. m. f.” and “e. m. f. contact to Ge” as abscissas are plotted against currents as ordinates. The results indicate a close connection between the direction of the rectified current and the thermoelec. effect. Finally, a study of the behavior of Ge contacts at temps greater than the reversal point has shown that the resistance of the contact on cooling is always greater. This is ascribed to the presence of a high-resistance oxide film.

H. R. MOORE

Data on the flow of electric current in quartz. V. E. WHITMAN. *J. Optical Soc. Am.* **12**, 31–43(1926).—The current is of the order of 10^{-16} amp. for a p. d. of 360 v. maintained between the 2 opposite sides of the specimen. The dielec. const. of fused quartz is 3.88 ± 0.02 ; *cryst. quartz*, 4.04 ± 0.04 .

H. R. MOORE

The use of the mercury cathode in anodic oxidation processes. I. SHCHERBAKOV. *Z. Elektrochem.* **31**, 617(1925).—Additional exptl. precautions to those in (*C. A.* **20**, 551), with particular reference to the use of a diaphragm for the sepn. of the supplementary hard metal (Fe) electrode.

GEORGE L. CLARK

Thermodynamic potential differences at the boundary of two liquid phases. III. SERG. VOZNESENSKII AND K. ASTACHOV. *Z. physik. Chem.* **118**, 295–300(1925); cf. *C. A.* **19**, 3204.—The distribution of HCl and H_2SO_4 between H_2O and phenol, and the e. m. f. of cells contg. HCl , H_2SO_4 or H_3PO_4 in distribution equil. between the aq. and phenol phases are measured. No new phenomena are described, and the measurements are of low precision.

F. C. KRACEK

The determination of p_{H} in fluids and suspensions. Practical application of Einar Billmann's quinhydrone electrode. C. W. G. HETTERSCHIJ AND J. HUDIG. *Chem. Weekblad* **23**, 2–3(1926).—For routine detn. of soil acidity the quinhydrone electrode is superior to any other method, because the potential is rapidly established and is const. Around p_{H} 7 the results are somewhat low, but soil p_{H} is usually below this value. One operator can make 240 detns. in 1 hr. A set of 8 cells (centrifuge tubes with a Pt electrode in each) is connected with a comparison quinhydrone electrode by means of an agar-KCl bridge and a 9-point contact. The 9th point affords connection with a normal cell for the standardization of the storage batteries. The potentiometer described in the following abstract and a Leeds-Northrup galvanometer are used for

the measurements. Nine cc. of the fluid is shaken with 50 mg. of quinhedrone and allowed to stand 2 min. before the measurement.

MARY JACOBSEN

A new method for determination of dielectric constants of electrolytes of high conductivity. H. HELLMANN AND H. ZAHN. *Physik. Z.* 26, 680-2(1925).—The "second Drude method" (a system of parallel wires, bounded on one side by a liquid condenser) is modified in that the damping of (Barkhausen) high-frequency oscillations at resonance in a circuit contg. the condenser is used as a measure for D instead of the place of the resonance point itself. The amplitude measured is compared with that obtained on replacing the condenser by a resistance wire of known inductivity. From curves of the resonance amplitudes as functions of the cond. σ of the soln. it is shown that between very low and very high σ values a sensitive range exists in which the amplitude varies considerably with D ; for a damping decrement of zero for the rest of the app. a ratio of 6:1 for $D = 50$ and 81 is possible. Low decrement of the instruments is absolutely essential. The sensitivity range can be varied by varying D or frequency; for D about 80 and using the shortest waves obtainable it lies around $\sigma = 0.05-0.1$ (5% NaCl).

B. J. C. VAN DER HOEVEN

The quantum theory of the dielectric constant of hydrogen chloride and similar gases. I. PAULING. *Proc. Nat. Acad. Sci.* 12, 32-5(1925).—Calcs. on the quantum theory. The exptl. points lie much nearer to a type of curve required by the classical theory.

GEORGE L. CLARK

Diamagnetism of nematic substances. G. FOEX AND L. ROYER. *Compt. rend.* 180, 1912-3(1925).—The magnetization coeff. of *p*-azoxyanisole in the solid state is independent of temp. At 116° , the nematic phase appears and the magnetization diminishes abruptly by about 17%, because of orientation of mols. by the magnetic field. The nematic phase ($116-134^\circ$) shows great variations of the magnetization coeff. with temp.; the value approaches the original value as the temp. increases and remains const. when the liquid phase is attained. The curve, magnetization coeff.-temp. may be produced to 95° for the nematic phase and the max. difference observed between 2 magnetizations in the liquid and nematic phases is greater than 18%. Whenever the substance solidifies, a different value is observed for the coeff. because of imperfect distribution of the tiny crystals making up the solid. Anisaldazine gave similar results.

B. C. A.

Magnetization of ferro-nickel (alloys) (thermomagnetic properties). M. PESCHARD. *Compt. rend.* 180, 1475-8(1925); cf. *C. A.* 19, 2773, 2907.—Alloys contg. more than 34.4% of Ni (Fe_2Ni) are reversible in the sense that their magnetic properties disappear and reappear at the Curie point, while alloys contg. less than this amt. of Ni are irreversible. If sufficiently cooled the latter acquire a strong magnetization which is connected with the change of the Fe from the γ to the β modifications. Under certain conditions, alloys in the " β " state exhibit reversibility. The various cases possible are discussed and the exptl. results expressed diagrammatically.

B. C. A.

Electrical birefringence of limonene. R. DE MALLEMAN. *Compt. rend.* 180, 1483-5(1925); cf. *C. A.* 18, 1078, 3527.—The Kerr const. for limonene has been detd. M.'s method measuring elec. birefringence (*Ibid* 176, 380(1923)) being used. The rotatory power remains const. within the limits of exptl. error in the elec. fields employed. The birefringence is small and positive in sign. The value of the Kerr const. in abn. units, 6.5×10^{-8} (15° , 0.546μ), is intermediate between the values of benzene and of toluene and about 4 times that of pinene. The significance of this no. from the point of view of structural formulas is discussed.

B. C. A.

Measurement of the light-scattering coefficients of some saturated vapors. SCOTT EWING. *J. Optical Soc. Am.* 12, 15-26(1926).—The intensity of the scattered light was detd. over the temp. range $0-100^\circ$ for Et_2O , C_6H_6 , CHCl_3 , EtOH and MeOH , and was compared with the intensity of the incident light by a photographic method. The effective wave length of scattering was found to be 4446 \AA . U. with a probable error of 7 \AA . U. Coeffs. of scattering deduced exptly. are in good agreement with the measurements of Ramanathan and with theoretical values calcd. from the Einstein-Smoluchowski equation. In using the E.-S. equation, the compressibilities β were estd. from the velocity of sound in the vapors, their ds. and sp. heats. The values of ρ (ratio of intensity of vertically and horizontally polarized components of scattered light) were taken from the literature.

H. R. MOORE

Colors shown by Nobili's rings. B. N. CHUCKURTI. *Proc. Indian Assoc. Cult. Sci.* 9, 82-91(1924).—Nobili's rings may be obtained with a variety of cathodes and electrolytes, but the finest display results when a brass plate is used in PbSO_4 or MnSO_4 soln. The rings consist of granular particles of metal or oxide and are largest ($d = 500 \mu$) near the center and smallest ($d = 275 \mu$) at the periphery. It is suggested

that the colors are due to diffraction by these granules, and the similarity to metal colors produced by heat is pointed out.

Very thin, transparent metal foils. CARL MÜLLER. *Z. Physik* 34, 43-6(1926).—A review (cf. *C. A.* 20, 525) and Brit. pat. 230,456 (*C. A.* 19, 3225).

H. C. UREY

World-geometrical properties indicated by quantized world-lines of the electron in the hydrogen atom. E. REICHENBÄCHER. *Z. Physik* 32, 505-17(1925).—From a consideration of the relativity geometry of the quantized electron orbits in the H atom, it is deduced that the electron is characterized by a fundamental "proper time," h/m_0c^2 (h = Planck's const., m_0 = mass of electron at rest, c = velocity of light); at the end of this time, or some multiple of it, the electron must return to its original condition, or emit radiation.

B. C. A.

Equilibrium of the calcium chromosphere. E. A. MILNE. *Month. Not. Roy. Astr. Soc.* 85, 111-41(1924).—A full soln. is obtained of the problem of the equil. under radiation pressure of an atm. consisting of atoms supposed to possess only 2 stationary

states--the normal and 1 excited state. This special case of the general problem of equil. corresponds fairly with an atm. absorbing spectral lines derived from the normal state of the atom, such as the principal series of Na, Ca, Ca^+ , etc. The law of d. deduced for an atm. fully supported by radiation pressure is that the d. at any point is inversely proportional to the square of the height of the point above a certain fixed level. For an atm. only partly so supported, the law is quite different, and the d. decreases exponentially with height. The least departure from exact balance between radiation pressure and gravity at great heights should cause an overwhelming concn. of the atmosphere into the lowest levels. This is in agreement with the great variations observed in the height of the Ca chromosphere. Conclusion: The high-level Ca chromosphere of the sun must be fully supported by radiation pressure. The investigation confirms M.'s previous est. of the life of an excited atom deduced from solar data.

B. C. A.

Diamagnetism and the size of ions. G. JOOS. *Z. Physik* 32, 835-9(1925).--The distance of the outer electrons from the nucleus is calculated from Langevin's theory and agrees remarkably well with the result obtained from the theory of the crystal lattice.

B. C. A.

The relative size of atoms and ions. RITA BRUNETTI. *Atti accad. Lincei* [6], 2, 410-5(1925).--In extending previous work (C. A. 20, 540) B. has investigated the existence of variations in vol. of electronic systems. From the considerations and data developed, it is concluded that while the ions of the alkali metals have a smaller vol. than that of the atoms, the vol. of negative ions of the halogens and of the metalloids is greater than that of the atom.

E. J. WITZEMANN

Polarization of resonance radiation and the duration of excited state. K. R. RAMANATHAN. *Proc. Indian Assoc. Cult. Sci.* 9, 93-102(1925).--The changes of polarization of the resonance radiation of Hg vapor in weak magnetic fields (Wood and Ellett, *Proc. Roy. Soc.* 103A, 396(1923); cf. C. A. 18, 1610) can be explained by taking into account the Larmor precession of the orbit of the electron round the direction of the magnetic field, and the finite duration of the excited condition of the atom. The duration of the excited state required to explain the decrease of polarization in Hg vapor resonance when a magnetic field is applied parallel to the direction of observation, and perpendicular to the incident beam of light, is consistent with Wien's detn. of the same quantity (C. A. 18, 2107). The changes in intensity and polarization of the resonance radiation when the Hg vapor is mixed with H, He, Ar, or air (Wood, C. A. 17, 493) can be explained by assuming a finite time of excitation of the atom, and that the effect of a collision is either to destroy the radiation or to disturb the polarization so as to make its direction random.

B. J. C. VAN DER HOEVEN

The translation of kinematical and mechanical relations into terms of the quantum theory. W. HEISENBERG. *Z. Physik* 33, 879-93(1925).--An attempt is made to develop a quantum mechanics such that the observed frequencies and amplitudes of the light emitted by atoms shall be those entering into the "motion" of the particles composing the atom. This is done by assuming that the motion can be expanded into a periodic function similar to a Fourier expansion but having the quantum frequencies required by the Bohr frequency condition instead of the usual frequencies of the classical mechanics. The amplitudes are those required to give the intensities of the light emitted. The quantum condition is stated in the form of a difference equation. The energy of the steady states of an inharmonic oscillator and a rotator is derived and it is found that half quantum nos. are to be used for the inharmonic oscillator and that the energy of the rotator is of the form const. $(n^2 + n + 1/2)$, where n is the quantum no. The frequency in the "motion" is shown to be equal to $(W_1 - W_2)/h$ as required by the Bohr frequency condition. The Goudsmit-Kronig-Hönl intensity formula is derived (cf. following abstr.).

H. C. UREY

Quantum mechanics. M. BORN AND P. JORDAN. *Z. Physik* 34, 858-88(1925).--An extension of the work of Heisenberg (cf. preceding abstr.). It is shown that Heisenberg's quantum mechanics can be most easily handled by means of the mathematics of matrices and his method of multiplication, the quantum condition, etc., are expressed in terms of matrices. The original must be consulted for details. The more outstanding features of the system are: the frequency in the "motion" is the quantum frequency; time can be eliminated from the equations so that the terms mechanics, motion, velocity, etc., have no real meaning; the steady states, measured frequency and amplitudes as

detd. by the light emitted remain. The inharmonic oscillator is considered in detail and the entire soln. secured without reference to classical mechanics and the correspondence principle. An electromagnetic theory of light in terms of matrices is suggested. H. C. UREY

Commercial production of radium, mesothorium and helium. R. B. MOORE. *Ind. Eng. Chem.* **18**, 198–211 (1926).—Perkin Medal address in which the work of M. and his collaborators of the Bureau of Mines in the production of Ra, MsTh and He is reviewed and compared with other methods. The history of the use of He in aviation, including the Army and Navy developments, is also related in detail. S. C. L.

Uranium X, its extraction and estimation. RAJENDRALAL DE. *J. Sci. Assoc. Maharajah's Coll.* **2**, 43–52 (1925).—By using a β -ray electroscope and very thin films, the amt. of U X in a sample of $\text{UO}_2(\text{NO}_3)_2$ purified in 1921 was detd. The method of extn. was to dissolve the salt in a satd. soln. of NaF and then carry down the U X with a colloidal sol of $\text{Fe}(\text{OH})_3$. Various explanations of the process are offered

MARIE FARNSWORTH

Observations on space radiation penetrating to sea level. G. HOFFMANN. *Physik. Z.* **26**, 669–72 (1925).—H. previously found (*C. A.* **18**, 3001) that the ionizing radiation present in a brass vessel with 2-mm. walls at Koenigsberg had a power of 4.70 J (one J produces one ion pair per sec. in one cc. of normal air), inside 3-cm. lead armor 1.56 J, 12-cm. lead 1.00 J. In order to test for more strongly penetrative space radiation expts. were made inside 32 cm. lead; 0.96 J was measured. This proves that besides the own radiation of armor and instruments some radiation penetrates from outside but only $1/8$ of that calcd. from the 1.4 J. (Kolhörster) value for open-air radiation at sea level. The latter value is apparently too high. H. even feels inclined to assume that this small amt. of strongly penetrative radiation is solely due to the presence of known Ra elements (γ -rays). He gives evidence that even 32 cm. lead does not entirely hold back short γ -waves (the coeff. of absorption may be as low as 0.18 per cm). In a discussion of the original Hess expts. (*C. A.* **7**, 3568) it is shown that because of the scattering instead of absorption of γ -rays by light elements (water and air) Hess' principal arguments are invalid.

B. J. C. VAN DER HOEVEN

The dispersion constants and critical electron velocities of molecular hydrogen. H. SCHÜLER AND K. L. WOLF. *Z. Physik* **34**, 343–6 (1925).—It is possible to calc. the dispersion of H by means of the formula $n-1 = c_1/(v_1^2-v^2) + c_2/(v_2^2-v^2)$ by substituting for the characteristic frequencies v_1 and v_2 values corresponding to the wave lengths $\lambda_1 = 942.6$ A. U. and $\lambda_2 = 734.5$ A. U. (13.1 and 16.8 v. resp.). These 2 characteristic frequencies are assumed to be centers of gravity for some absorption spectrum of the hydrogen molecule.

H. C. UREY

The excitation of the spectrum of hydrogen by electron collision. P. M. S. BLACKETT AND J. FRANK. *Z. Physik* **34**, 389–401 (1925).—It is shown experimentally that in 1 collision between an electron and a H_2 mol. the H_2 can be decomposed into a normal atom and an excited atom and that the continuous spectrum appears at the same time. When a discharge tube is in the red condition (at. H) the Doppler effect of the H_α line is small but when the tube is white (mol. H_2) this line shows a large Doppler effect even at liquid-air temps. This must be due to the velocity of sepn. of the 2 atoms of the mol. It is suggested that the sepn. of the atoms is due to an electron being removed very suddenly to a higher energy level so that the nuclei are under a large force of repulsion, resulting in their sepn. into a normal atom and an excited atom moving with high velocity.

H. C. UREY

Lead peroxide as a detector (in wireless telegraphy). J. CAYREL. *Compt. rend.* **181**, 1127–8 (1925).—A piece of PbO_2 from a storage-battery plate or a film of PbO_2 deposited electrolytically on a Pb, Pt or C plate possesses, under certain conditions, intense detecting properties, the detecting current passing from the plate to the point. Al, Mg, Ca, Zn, Sn, etc., points can be used without special precautions. Pt, Au, Ag, Ni, Cu, Fe, etc., points do not ordinarily detect, but can detect if the contact is exceedingly light. If sliding contact is used instead of a permanent contact, detection is extremely sensitive, irrespective of the nature of the point. With 2 points of the same nature, better detection is obtained with the lighter contact and the one having the smaller contact area. With 2 points of different nature, the degree of detection depends mainly on the nature of the resp. points. Above a certain current d. detection ceases, so that a fairly large contact point, or a sliding contact, should be used. The favorable action of a sliding contact may be due to the suppression of coherence when the passing of the current through the contact tends to produce.

A. PAPINEAU-COUTURE

Red limit and work of escape of photoelectric electrons. R. SUHRMANN. *Z. Physik* **33**, 63–84 (1925).—The curves of photoelectric sensitivity for Pt, Au and Ag near

the red limit were measured with the most delicate instruments possible. All 3 metals show the influence of surface films, but only Pt and Au show any considerable diminution in emission after continued heating at a high temp. to remove occluded gas—probably H in the case of Au and Pt, O in that of Ag. From the curves characteristic consts. can be deduced by applying the theory of thermionic emission, and the value for the work of escape and the red limit can be calcd. for zero abs. A temp. scale can be constructed and the photoelectric cell may be used as a total-radiation pyrometer.

B. C. A.

The energy required to split hydrochloric acid into atomic ions. E. C. KEMBLE. *J. Optical Soc. Am.* 12, 1-13(1926).—A new analysis of the band system of the HCl mol. is given, taking into account the displacement of the lines due to the isotopic effect. —Preliminary studies showed that the current flowing from a Pt foil to a grid in a tube designed for detection of secondary emission increased when the foil was illuminated with light from a C arc, tungsten-filament lamp, and a Nernst lamp. With an improved app. the velocity distribution of the secondary bundle was detd. for incident electrons of 4-12 v. velocity and with a negative p. d. of 15 v. applied to the foil. The effect of light is attributed to a diminution of electron reflection, since with opposing fields its action is negligible (cf. Farnsworth, *C. A.* 17, 235; 19, 1092). Further, it was impossible to demonstrate a systematic dependence of the effect on the velocity of the primary electrons, possibly because the intensity of the reflected bundle is not influenced by a high velocity of incident electrons. The conclusion is reached that light exerts a purely thermal effect in accentuating secondary emission, since no change was noticed in studying restricted spectral regions from the ultra-violet to the infra-red, and identical results were obtained on illuminating the back side of the foil. This evidence frustrates a possible photoelec. interpretation of the effect.

H. R. MOORE

A characteristic effect produced by bombarding platinum with slow electrons. ERIK RUDBERG. *Medd. Vetenskapsakad. Nobelinst.* 6, No. 12, 9 pp.(1925)(in German). —Preliminary studies showed that the current flowing from a Pt foil to a grid in a tube designed for detection of secondary emission increased when the foil was illuminated with light from a C arc, tungsten-filament lamp, and a Nernst lamp. With an improved app. the velocity distribution of the secondary bundle was detd. for incident electrons of 4-12 v. velocity and with a negative p. d. of 15 v. applied to the foil. The effect of light is attributed to a diminution of electron reflection, since with opposing fields its action is negligible (cf. Farnsworth, *C. A.* 17, 235; 19, 1092). Further, it was impossible to demonstrate a systematic dependence of the effect on the velocity of the primary electrons, possibly because the intensity of the reflected bundle is not influenced by a high velocity of incident electrons. The conclusion is reached that light exerts a purely thermal effect in accentuating secondary emission, since no change was noticed in studying restricted spectral regions from the ultra-violet to the infra-red, and identical results were obtained on illuminating the back side of the foil. This evidence frustrates a possible photoelec. interpretation of the effect.

H. R. MOORE

Molecular refraction of simple compounds. K. F. HERZFELD AND K. L. WOLF. *Ann. Physik* 78, 195-203(1925); cf. *C. A.* 19, 1223.—From dispersion data of NaCl and KCl conclusions are drawn on mol. refraction calcs. of simple salts with ions similar to those of noble gases. The characteristic wave length of the cation is calcd. from the relation $Q = Q_G + Q_E = N_A h \nu = 289/\lambda$, where Q_G is the Coulomb fraction of space energy, and Q_A is the electron affinity of the free Cl atom. The "electron no. per ion" is a fundamental datum, and is estd. from the total no. of electrons of the corresponding noble gas. The dispersion attributed to the main term is produced by 95% of these electrons, and the remaining 5% is ascribed to the resonance line or characteristic frequency secured from the limit of continuous absorption. With this method the mol. refractivities of the anions and cations of the halide alkali salts are calcd., and are found to be in substantial agreement with the data of Fajans and Joos (*C. A.* 18, 2103) and Spangenberg (*C. A.* 18, 488). The following values of the electron affinity of the halide ions in kg. cal. are given: F 105, Cl 88, Br 89, I 81. Finally, data are given for the mol. refraction of the O ion in alk. earth oxides, and similarly the fractions attributable to the cations and anions, resp., for the H halides.

H. R. M.

Diffusion of slow electrons in an electric field. G. HERTZ AND R. K. KLOPPERS. *Physik. Z.* 26, 868-70(1925); cf. *C. A.* 19, 2908.—The mean wandering velocity or diffusion of electrons in an elec. field is a function of the mean free path, velocity and the elec. field. In several detns. a const. accelerating p. d. is maintained between a wire supported in the center of a tube and 2 plates placed equidistantly. When the ratio of the currents for 2 different p. ds. is plotted against $V_2 - V_1$ (difference of the applied voltages), curves are obtained in Ne and A which bear a formal resemblance to the curve developed from theoretical considerations.

H. E. MOORE

Action of visible light on electrodes. RENÉ AUDUBERT. *J. phys. radium* 6, 313-22(1925).—When light from a 20-amp. Hg arc maintained at 110 v. and from a 2500-c. p. W N₂-filled lamp is allowed to fall on electrodes of Hg, Ag, Cu and Au immersed in solns. of their salts and other inorg. salts, e. m. fs. of the order of 10^{-7} to 5.0×10^{-7} v. are produced. Gas occlusion vitiates the reproducibility of the results. Some attempt was made to study the variation of the effect with wave length, and in general

the threshold frequency of the photovoltaic effect was displaced to higher frequencies for the more electropositive metals. The photovoltaic effect thus bears a resemblance to the photoelec. effect, although V in Einstein's fundamental equation $eV = h\nu - h\nu_0$ is a function of the incident luminous intensity. E. m. fs. resulting in the movement and diffusion of ions mask the primary electron emission occurring at the electrodes. Hence $e = \phi(I, C, T)$, denoting intensity concn., and temp., resp. Athanasiu's interpretation, attributing the photovoltaic effect to chem. action and heat effects at the electrodes is criticized in the light of these new results (cf. Athanasiu, *C. A.* 18, 1243, 3008).

Action of light on chlorine dioxide. H. BOOTH AND E. J. BOWEN. *J. Chem. Soc.* 127, 510-3(1925).—In the abstract in *C. A.* 19, 2453 "ClO" should read "Cl₂O."

H. R. MOORE

E. J. C.

Relations involving internal pressure, intensity, mercury transfer, cross-section and electric conditions in mercury-vapor lamps. GEO. S. FORBES AND P. A. LEIGHTON. *J. Optical Soc. Am.* 12, 53-63(1926); cf. *C. A.* 19, 1093, 2915. —Numerous curves establish the dependence of internal pressure on cross-section, voltage gradient and current. Internal pressure, however, is independent of the cathode or anode temps., as measured with thermocouple inlets and also arc length within the range 15-37 cm. With increased potential gradients, the positive-ion current gains on the electron current as expected from kinetic considerations.

H. R. MOORE

An attempt to derive the lattice type from the assumption of isotropic polarizable ions. F. HUND. *Z. Physik* 34, 833-57(1925).—A mathematical study of the crystal lattice types to be expected on the assumption of isotropic ions of given charge and polarization const. and a non-coulomb repulsion of the form b/r^n . Three types of lattices are found to be stable, depending on the magnitude of the polarization of the ions. Ions with slight polarization form the coordination type lattice, those with larger polarization form a mol. lattice or a layer lattice. The crystal structures of many substances are discussed.

H. C. UREY

The K β lines in the X-ray emission spectra of the elements phosphorus and potassium. O. LUNDQUIST. *Z. Physik* 33, 901(1925).—It is shown that the intensities and wave lengths of the group of K β lines in the spectrum of P depend on its chem. combination, and also, with the element, on material of the anticathode of the X-ray tube. Twelve different K compds. were tested for a similar effect of the K β lines, but none could be found.

S. K. ALLISON

Continuous X-ray spectrum and Planck's radiation law. A. MARCH. *Ann. Physik* [iv], 75, 711-42(1924).—Mathematical, with a discussion of exptl. results. The continuous background is regarded as a heat radiation emitted by atoms of the anticathode which have been strongly heated by collision with electrons.

B. C. A.

Crystal for wave-length measurements of soft X-rays. L. PAULING AND A. BJÖRKESSON. *Proc. Nat. Acad. Sci.* 11, 445-7(1925).—Hexagonal β -alumina possesses an unusually large grating-const., rendering it very suitable for measurements of soft X-rays. For the line CuK α , the const. is 11.240 A. U. and for AgL α , 11.225 A. U. The difference is a real effect. The crystal gives strong reflection.

B. C. A.

Barium sulfate as a protective material against Röntgen radiation. F. L. HUNT. *Am. J. Roentgenology* 14, 524-8(1925).—BaSO₄ in the form of bricks or plaster is sometimes used as a substitute for metallic Pb as protection against X-rays. Comparisons of plaster (1 part finely ground and 2 parts coarsely ground BaSO₄ and 1 part of portland cement) with various thicknesses of metallic Pb were made, with X-rays of a large range of penetrating power. A "protective coeff." was obtained by dividing the Pb equiv. thickness by the thickness of the plaster. This coeff. varies with the voltage, passing through a max. at 110 kv. for the thickness of plaster used. For complete protection at 100 kv. 3 mm. of Pb is necessary, and at 200 kv., 6 mm. The plaster equivalents are 25 mm. and 70 mm., resp.

EDITH H. QUILMBY

The line and band absorption spectrum of copper and its fine structure lines. HILDEGARD STRÜCKLEN. *Z. Physik* 34, 562-85(1925).—The absorption spectrum of Cu was investigated, a spark under water being used. The line absorption spectrum consists of doublet and quartet systems. The former is due to the excitation of the 4₁ electron and the latter to excitation of one of the 3₁ electrons. The fine structure of the at. lines varies greatly with the conditions of excitation and it is suggested that these are very short bands due to very unstable mols. It is shown that the moment of inertia calcd. is of the expected order of magnitude. An absorption band (probably CuH) with P and R branches at 2240 A. U. is observed and is degraded toward the red. The moments of inertia in the initial and final states are 12.7×10^{-40} and 14.2×10^{-40} g. sq. cm., resp.

H. C. UREY

The theory of broadening of spectral lines. LUCY MENSING. *Z. Physik* **34**, 611-21(1925).—The broadening of spectral lines due to the perturbing fields of neighboring atoms should be greater when the perturbing effect is due to like atoms, since the perturbations will be greater because the frequencies in the motion are commensurable. H. C. UREY

Influence of different nuclei on absorption spectra of substances. J. E. PURVIS. *J. Chem. Soc.* **127**, 2771-6(1925); cf. *C. A.* **18**, 498, 1242, 1434.—The absorption spectrum bands of Ph, PhCH₃, thymol and camphor salicylates are comparable with those of salicylic acid, the difference from the latter and from one another being chiefly in position and strength. The basic nucleus is the chief agent in the sp. absorption of the benzoate, citrate and hydrochloride of caffeine. In the salicylates of theobromine, caffeine, phenazone and quinine the acid nucleus modifies that of the basic nucleus to a larger extent, but least in the quinine compd. In *o*-acetoxybenzoic acid, and in the *o*-acetoxybenzoates of theobromine and quinine the replacement of the H of the OH group by the acetyl group exerts a very great influence on the final absorption. The sp. and general absorption of these substances, therefore, depends upon 3 factors, the nature of the base, the nature of the acid and the presence of H in the OH group. The expts. indicate that the replacement of the H atom of the OH groups by another radical, not itself possessing sp. absorption, decreases the absorption capacity of the other parts of the mol. E. P. WIGHTMAN

Quantum analysis of new nitrogen bands in the ultra-violet. R. T. BIRGE AND J. J. HOPFIELD. *Nature* **116**, 15(1925).—A group of strong bands in the predicted position (cf. *C. A.* **19**, 600) has been analyzed, but the progressions are unexpectedly not related to those of any other analyzed group of N, or of any other substance. The equation for the new group is $\nu = 68,956.6 + (1681.45n' - 15.25n'^2) - (2345.16n'' - 14.445n''^2)$, where n' varies from 0 to 9 and n'' from 0 to 3 only. B. C. A

Hydrogen spectrum of constant frequency-difference. J. W. NICHOLSON. *Month. Not. Roy. Astr. Soc.* **85**, 656-9(1925).—Among the lines of the secondary spectrum of H showing a normal Zeeman effect, and therefore probably of at. origin, a no may be picked out between 3732.25 and 4966.98 Å. U. which have an approx. const. wave-number difference of 1313. Another large group nearer the red end has a wave-number difference which is nearly the same, namely, 1300. The lines of these 2 groups which have certain members in common, are also most characteristically unaffected by the presence of He. They appear to belong to a series spectrum nearer to the Ne than to the He type, and they show a certain resemblance to the nebular and to the Wold Rayet spectra. Another class of lines previously described (*C. A.* **19**, 3220), which show no Zeeman effect, form widely sepd. bands of mol. origin. B. C. A

Infra-red emission and absorption of potassium vapor. A. L. NARAYAN AND D. GUNNAYA. *Proc. Indian Assoc. Cult. Sci.* **9**, 1-14(1924); cf. *C. A.* **18**, 1086.—In K vapor at 500-700°, the existence of Moll's line at 3.65 μ and Paschen's line at 2.72 μ has been confirmed, and a new line at 1.2 μ found. Below about 600°, the vapor exhibits no selective absorption. B. C. A

Absorption spectra of benzophenone derivatives. T. TASAKI. *Acta Phytochim.* **2**, 49-73(1925).—Benzophenone in 0.0001 *M* alc. soln. shows an absorption band at frequency 4000 Å. U., uninfluenced by methylation of the benzene nucleus. *o*- and *p*-hydroxy substitution have a much greater effect than *m*-hydroxy substitution. The *o*-hydroxy deriv. shows 2 bands, while *p*-hydroxy substitution has a bathochromic influence which is much stronger in the dihydroxy derivs. The 2,3,4-substituted compds. show in general a broad band at frequency 3200. Substitution in both nuclei shows in general a greater effect than substitution in one nucleus. The structural formulas of the naturally occurring cotoin, phlorhizin and phloretin are confirmed spectrographically. B. C. A

Opalescence of binary liquid mixtures. J. C. K. RAO. *Proc. Indian Assoc. Cult. Sci.* **9**, 19-60(1924).—The intensity and polarization of light scattered by dust-free mixts. of toluene and AcOH at the ordinary temp. and of MeOH and CS₂ over a range of temps. has been measured. Intensities show max. values at definite concns. and temps.; these maxima are steepest at the crit. temp. and very steep indeed at the crit. concn. The degree of polarization follows a similar course, and at the crit. temp. and concn. the scattered light is almost completely polarized. A formula based on Lorentz's electromagnetic theory is developed to express the amt. of scattering at right angles to the primary beam. B. C. A

The Zeeman effect in spectra of high order. S. GOUDSMIT. *Physica* **5**, 419-23(1925); cf. following abstr. B. J. C. VAN DER HOEVEN

The "g" values of terms in spectra of high order. S. GOUDSMIT. *Naturwissenschaften*

schaften 13, 1090-1(1925).—Preliminary report. When an electron is added to the electronic structure of an ion, the values of the resultant vectorial quanta \bar{R} and \bar{K} (Pauli) may or may not change independently of each other. In the first case the Landé "g" (spectral splitting) factor for weak magnetic fields can be calcd. according to Landé as for normal multiplets of high order. In the second case the J values (J is resultant of R and K) of atom (1) and electron (2) can be compounded immediately to \bar{J} of the complex, only limited by the condition: $\bar{J}_1 - J_2 + \frac{1}{2} \leq \bar{J} \leq \bar{J}_1 + J_2 - \frac{1}{2}$. Calcg. according to the Landé method, G. now finds for g from the g_1 and g_2 values of atom and electron: $\bar{g} = g_1(\bar{J}^2 - \frac{1}{4}) + (\bar{J}_1^2 - J_2^2)/2(\bar{J}^2 - \frac{1}{4}) + g(\bar{J}^2 - \frac{1}{4} + J_2^2 - \bar{J}_1^2)/2(\bar{J}^2 - \frac{1}{4})$. Other cases are briefly discussed. B. J. C. VAN DER HOEVEN

The spectra of hydrogen and helium. S. GOUDSMIT AND G. H. UHLENBECK. *Physica* 5, 266-70(1925).—A discussion of the theory of Wentzel (C. A. 19, 2913). According to W.'s theory the hydrogen and alkali spectra are similar; the electron energy $W(n,k) = RZ^2/n^2$ for both. The spectrum of neutral He can on the same principle be considered as similar to the alk. earth spectrum, the narrow doublets of ortho-He being undissolved triplets (cf. Pauli, C. A. 19, 2450). However, Wentzel's scheme is far from sufficient for explanation of the magnetic properties of the spectrum, particularly the normal Zeeman effect of the H fine structure and the He doublet. B. J. C. VAN DER HOEVEN

Chemiluminescence and heteropolar combination. A. PETRIKALN. *Z. Physik* 32, 569-74(1925).—The decompn. of the iodide of Millon's base is shown to be an endothermic reaction; above 350°, the decompn. is accompanied by the emission of light, the spectrum exhibiting the bands of HgI_2 and the Hg lines 4017, 4359, 5461 Å U; with a specially made spectrograph the line 2537 was obtained. Conclusion: The electron holding the Hg and N atoms together belongs to the 2s orbit. B. C. A.

Theory of diminution of fluorescence. A. PREDVODITELEV. *Z. Physik* 32, 861 71(1925).—The energy absorbed by a fluorescent substance is partly transformed into heat and partly radiated as fluorescence. A relationship is exhibited between the amt. of fluorescence and the sp. heat at const. vol. of the active mols. A method of calcg. the mean energy of the resonators is given and its relation to the amt. of fluorescence is deduced. B. C. A.

The chemical effects in ionized organic gases. S. C. LIND AND D. C. BARDWELL. *Science* 62, 422-4(1925).—This study initiated with C_2H_6 (C. A. 19, 440) has been extended to detns. of the M/N ratios and chem. behavior of the following substances when mixed with Rn: CH_4 , C_3H_8 , C_4H_{10} , C_2H_4 , C_2H_2 , $(CN)_2$, HCN and NH_3 . The satd. hydrocarbons CH_4 , C_3H_8 , C_4H_{10} show the same behavior as pure C_2H_6 ; i. e., they condense with elimination of H_2 instead of decomposing. CH_4 as well as H was found to be a product of condensation of C_2H_6 , C_3H_8 and C_4H_{10} ; for higher polymers small quantities of C_3H_8 and C_4H_{10} were formed. Nothing is known of the exact compn. of the yellowish brown liquid and solid condensates resulting from the action of the α -rays, but it is inferred that they possess some degree of unsatn. or consist of ring compds. since the H/C ratio is 1.8/1. The value of the M/N ratio (no. of mols. reacting per ion pair produced) increases with the degree of unsatn.; thus for satd. hydrocarbons $M/N = 1.4-2$, for double-bonded compds. approx. 5 as in C_2H_4 , and for triple-bonded compds. still higher (e. g., $(CN)_2$, 7; HCN, 10; C_2H_2 , 20). The oxidation of all the above compds is studied except C_3H_8 and HCN. Reaction kinetics of the oxidations of CH_4 and C_2H_6 are in conformity with the principle of the exclusivity of oxidation (C. A. 20, 145). Hydrogenation of C_2H_2 , of C_2H_4 (?) and of $(CN)_2$ and polymerization of C_2H_2 , $(CN)_2$ and HCN have been accomplished. It was found that Na ions are as effective in causing the polymerization of C_2H_2 , $(CN)_2$ and HCN as their own ions. Since the N_2 did not enter permanently into combination, it seems clear that this phenomenon is an instance of a new type of catalysis in the gaseous phase, namely *ionic catalysis*. H. R. MOORE

The absorption spectrum and the photochemical decomposition of acetone. C. W. PORTER AND C. IDINGS. *J. Am. Chem. Soc.* 48, 10-4(1926). A detn. was made of the molal extinction coeffs. for ultra-violet light of gaseous Me_2CO . All the light absorbed is effective in bringing about decompn. By means of Me_2CO filters it was found that radiation corresponding to the peak of the absorption curve does not possess any special significance with regard to the light which brings about the reaction. By means of crotonic acid filters it was shown that decompn. is not dependent upon the presence of the shorter wave lengths within the absorption region. E. P. WIGHTMAN

Visible decomposition of silver halide grains by light. A. P. H. TRIVELLI AND

S. E. SHEPPARD. *J. Phys. Chem.* **29**, 1568-82(1925).—The photochem. darkening of specially prepd. AgBr crystals has been studied microscopically. It is shown that the decompn. occurs in definitely oriented patterns depending upon the growth and structure of the crystals. The visible darkening of the AgBr grains of emulsions was studied statistically. In contrast to the specially prepd. crystals, the decompn. is largely irregular. The visible sensitivity increases with the size of grain in the same emulsion. The lack of parallelism between the developable sensitivity and the visible sensitivity of different emulsions is due to the fact that the visible sensitivity is relatively independent of sensitivity nuclei. A tentative hypothesis is proposed. It is suggested that the photochem. decompn. is oriented in the crystal according to the gradients of ionic deformation, or perturbation of electron orbits following certain directions of growth. Since sensitivity nuclei, as also reduced Ag, will induce marked deformation in contiguous AgBr, the decompn. becomes autocatalytically oriented. This explains the contrast in behavior between the special AgBr crystals and emulsion grains as well as the effect of size.

E. P. WIGHTMAN

Photochemical kinetics (reply to J. Plotnikov). RUDOLPH WEGSCHEIDER. *Rec. trav. chim.* **44**, 1118-20(1925). (In German.)—Reply to P.'s criticisms (*C. A.* **19**, 3427) of the work of W. (*C. A.* **17**, 1747) and of Langedijk (*C. A.* **19**, 2301). W. and L. are in agreement against P.

E. J. WITZEMANN

Production of ozone by silent discharge at low pressures. E. WARBURG AND W. RUMP. *Z. Physik* **32**, 245-51(1925).—Siemens tubes were used in which the passages for the gas varied from 1 to 3.5 mm. in width. The O contained 3.5% of N, and the potential varied from 5000 to 9000 v. As the pressure was reduced the current across the tube increased, but the yield of O₃ diminished, at first slowly, then more rapidly, and for pressures below 200 mm. it was proportional to the pressure. With air the yield of O₃ is greater than the value corresponding with the partial pressure of the O

B. C. A.

Polymerization and hydrogenation of ethylene by means of excited mercury atoms. A. R. OLSON AND C. H. MEYERS. *J. Am. Chem. Soc.* **48**, 389-96(1926).—C₂H₄ in presence of Hg vapor was exposed alone and with H₂ in a quartz vessel at low pressures and moderate temps. to radiation from a Hg lamp. Pressure readings showed that C₂H₄ first decompd. slightly, and then the remainder polymerized. With H₂, C₂H₆ was formed, the rate being proportional to the sq. root of the H₂ concn. A mechanism is proposed

A. W. FRANCIS

Measurements of the energy absorption attending certain photochemical reactions with iodine. B. K. MUKERJI AND N. R. DHAR. *Z. Elektrochem.* **31**, 621-5(1925).—The kinetics of the reactions of I₂ with KCHO₃, K₂C₂O₄, FeSO₄, NaNO₂ were investigated and the true energy absorptions calcd. by subtracting the measured value for pure H₂O in the same reaction cells. (For previous studies of the kinetics of the I₂-NaCHO₂ and I₂-K₂C₂O₄ reactions, see Dhar, *C. A.* **12**, 111; **17**, 3837. For the I₂-FeSO₄ reaction, Banerji and Dhar, *C. A.* **18**, 2634.) A 100-c. p. Pointolite lamp was used as source, and the energies were detd. with a radiomicrometer. Photographs taken with a quartz spectrograph revealed absorption for all solns. of wave lengths in the range 4600-3160 Å. U. The mean wave length 3880 Å. U. was taken for the quantum efficiency calcs., on the assumption that the reactions are due entirely to activation of the I₂ mol. The yields of the K₂C₂O₄, FeSO₄, and NaNO₂ reactions indicate the transformation of only 1 mol. of I₂ for every 28, 15 and 49 hν absorbed, a substantial departure from Einstein's law of photochem. equivalence. For the KCHO₃ reaction, on the other hand, 10 I₂ mols. are transformed per hν absorbed. A possible interpretation is suggested, taking into account the exothermal and endothermal character of the various reactions.

H. R. MOORE

Ozone formation by electron impact. F. KRÜGER AND O. UTESCH. *Ann. Physik* **78**, 113-56(1925).—A repetition of Moeller's work (*Dissertation*, Danzig, 1912) on the action of cathode rays admitted through a Lenard window on flowing O₂. In these expts. a glow rectifier was used in the secondary circuit imparting electrons with an av. velocity of 24-26 kv. O₃ was estd. by liberation of I₂ from neutral KI soln. The ratio of the no. of O₃ mols. formed to the no. of ions produced (*M/N* ratio) was secured by measuring the satn. current in a condenser filled with O₂ of d. sufficient to absorb all the electrons. The no. of O₃ mols. was always in large excess of the no. of ions formed, usually of the order of 20-40 according to the speed of flow of O₂. The distribution of the total energy of the cathode rays was detd., and found to be 5-11% for O₃ formation, 2-4% for secondary rays produced in the gas and 80-90% as heat. The following reaction mechanism is recommended: O₂ + e → O₂* (1), O₂* → O + O (2), O + O₂ → O₃ (3), where O₂* is an energy-rich mol. according to the

Stern-Volmer conception. The formation of O_2^* should, therefore, add to the transformation produced by O_2 ions alone. K. and U. point out that the action of light and electrons in O_2 synthesis should be comparable according to the quantum relation $eV = h\nu$, but a dense stream of electrons of velocity less than the ionization potential of O_2 should be employed for testing the efficacy of the relation. H. R. MOORE

Characteristic reactions induced by light-excited bromine. J. EGGERT, F. WACHNOLTZ AND R. SCHMIDT. *Physik. Z.* 26, 865-8(1925).—A continuation of work previously reported by E., and by E. and Borinski (*C. A.* 18, 3548; 19, 1224) on the photochem. sensitization of Br in the conversion of *diethyl maleate* into *diethyl fumarate*. The reaction is carried out in CCl_4 soln. with the blue light 436 $m\mu$ of the Hg arc. The exptl. characteristics of the isomeric change are given in a table recording the dependence of ϕ , the no. of mols. transformed per quantum absorbed, and α , the no. of Br_2 mols. added, on various conditions. The postulate of the existence of the intermediate compd. diethyl dibromosuccinate in the direct as well as the reverse change is borne out by the facts, although no attempt was made to isolate this substance. At 21° and with 0.1 N Br_2 the values of ϕ and α are 295 and 8.2, resp. These quantities, moreover, are independent of the following factors: (1) light intensity with the limits 1.5-0.25 Hefner candles, (2) ester concn. within the limits pure ester to 70 mols. CCl_4 , (3) reaction temp. The exptl. independence of ϕ of the concn. of Br_2 within the limits 0.03-0.3 N is taken as the essential datum in formulating theories of reaction mechanism. Time of transformation of the maleic ester mol. must be of the order of 3×10^{-11} sec., since this is the approx. duration of the excited Br_2 mol. H. R. MOORE

4—ELECTROCHEMISTRY

COLIN G. FINK

New electric furnace. ANON. *Iron Age* 116, 1453(1925).—The Kay furnace has 2 spouts, 1 at each end. The lining converges toward the spouts and makes possible the pouring of metal from considerable depth below the slag. The position of the electrodes can be altered with respect to the furnace wall so as to prevent the concn. of heat at any particular part of the furnace. A. D. SPILLMAN

New high frequency induction furnaces. DUDLEY WILLCOX. *Metal Industry* (N. Y.) 23, 401-2(1925); cf. *C. A.* 19, 1170.—In the brass melting furnace described the crucible is surrounded by a coil, an in. of insulation sepg. the two. The furnace housing can be lowered away from the crucible so that the latter may be readily poured and any no. of different alloys may be produced. Among the advantages and features of this furnace are: that the crucible is never hotter than the metal and therefore the crucible life is longer; violent stirring results from the induced currents set up in the bath. The crucible is practically the only thing that needs replacing, the efficiency, if operation is just a few hrs. a day, drops off very little. On red brass 303 kw.-hrs. are required per ton on 8 hr. operation, and 286 kw.-hrs., on continuous operation, as against 351 and 273 kw.-hrs., resp., for other types of elec. furnace. High frequency furnaces are also in successful operation in melting precious metals and ferrous alloys and in heat treating steel. A. D. SPILLMAN

Ajax-Wyatt induction furnace for brass melting. ANON. *J. four élec.* 34, 233-5 (1925).—The standard capacity of the European type is 300 to 500 kg. of brass. The furnace requires for a 300-kg. charge 74 kw., 50 cycle, monophasic current at about 440 v. in the primary circuit. The av. for 1 heat is 4.69 kg. per kw.-hr. or about 200 kw.-hrs. per ton with 78.5% efficiency for a 70-kw. furnace. Loss by volatilization is about 1.5%. Production costs are tabulated in francs for a 65:35 brass. Sketches of the furnace are given. C. J. BROCKMAN

Electric furnace linings. G. F. HUGHES. *Metal Ind.* (N. Y.) 23, 487-90(1925).—H. discusses refractory problems in non-ferrous induction and rocking arc elec. furnace

melting, emphasizing furnaces in which the refractory acts as an insulator for the generated heat. In the rocking arc type of furnace for brass melting, asbestos paper is placed next the shell followed by a course of fire-brick. Trouble is encountered in failure of the refractory bushing by which the C electrode is held in the shell wall, it generally being necessary to replace the bushing twice before completely relining. Several days of preheating with a charcoal fire before starting the arc is important. In the *Ajax-Wyatt* type of induction furnace, asbestos paper is placed next the shell followed by a layer of *sil-o-cel* or *non-pareil* brick. In melting yellow brass alloys, $\text{Al}_2\text{O}_3\text{-SiO}_2$ refractory linings have also been used successfully. The desired refractory is one which will permit melting of alloys contg. 80% Cu and over, combined with Zn and alloys of Sn and Cu contg. 1-8% Sn. *Chrome base cements* have given consistently good results.

Power factor problems. E. V. CLARK, E. W. DOREY, *et al.* *Electrician* **96**, 167, 172(1926).

C. G. F.

Electrical manufacture of carbon black. J. J. JAKOSKY. U. S. Bur. of Mines, *Tech. Paper* **351**, 42 pp.(1924)—The ordinary types of app. for the fixation of N by elec. methods proved unsuitable for the production of C black from natural gas. By passing natural gas through an arc formed by direct or alternating current in an exptl. app. it is possible to sep. a considerable proportion of C. It is also possible to produce C black by means of an elec. arc from various oils or org. liquids, e. g., kerosene, gasoline, benzene, creosote, or alc.; O compds., such as creosote, appear to need less expenditure of power than paraffin hydrocarbons. C black produced by such elec. processes compares favorably with the better grades of ordinary C black both in tinting strength and particle size. When dispersed in oil, unlike ordinary C black, it does not tend to agglomerate. The elec. process is considered to have good industrial possibilities, particularly in view of the present uneconomical method of producing C black by burning natural gas.

B. C. A.

The formation of ozone from air under increased pressure. H. V. WARTENBERG AND M. TREPPENHAUER. *Z. Elektrochem.* **31**, 633-6(1925). It has been observed by Warburg (*C. A.* **18**, 1946) that in mixts. of O and N there was a proportionality between the amt. of O_3 formed by elec. discharge and the partial pressure of O, the total pressure of the gas mixt. having been kept const. This fact suggested the study of formation of O_3 at pressures higher than normal. Theoretically an increase in the amt. of O_2 should be expected; on the other hand an increased pressure might affect the discharge. Actually it was found that the amt. of O_3 first increases with increased pressure, but quickly decreases when the pressure exceeds 2 atm. There is no prospect of a technical application of this method, since the necessity of building of gas-tight and more resistant ozonizers renders the production of O_3 too expensive.

EMIL KLARMANN

The production of ozone by high frequency alternating currents. H. V. WARTENBERG AND M. TREPPENHAUER. *Z. Elektrochem.* **31**, 636-41(1925). The influence of the frequency of elec. discharges on the yield of O_3 has been previously investigated (cf. *C. A.* **18**, 24), alternating currents having been applied with a number of cycles up to 10,000. Recently it has been shown by Warburg (cf. *C. A.* **18**, 1946) that the O₂ producing low frequency a. c. induces the formation of a superposed a. c. with a cycle number of about 10^6 ; the latter current, however, produces no O_3 . In order to verify this statement W. and T. studied the formation of O_3 with a c. the cycle number of which was between 10^4 and 10^6 . In pure O the energy yield, expressed in g. O_3 per kw. hr., decreases with the increase of the number of cycles when currents with 500 and 23,000 cycles are compared, the velocity of the O current being the same. An increased velocity of O, however, furnishes an increased energy yield (although a lower concentration) so that currents of 10,000 cycles may give the same energy yields as those of 500 cycles. Currents of 300,000 cycles give practically no yields in a stream of gas of normal velocity. In air higher frequencies do not increase the energy yields, but decrease the formation of NO. The expts. permit the conclusion that there is no pronounced difference between the chem. action of low- and of high-frequency currents. To account for the lower yields of O_3 when high-frequency currents are used, the assumption is made that the acceleration of the impacting electrons must reach a min. value before being able to split O_2 into O atoms; this is prevented by a too quick change of the direction of the elec. field. Similar conditions seem to prevail in the system $\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3$.

EMIL KLARMANN

The electrodeposition of nickel. C. H. PROCTOR AND O. J. SIZELOVE. *Metal Ind.* (N. Y.) **23**, 415-6(1925).—The value of inert salts in Ni plating solns. and their max. of efficiency is a question which should be detd. Solns. high in Na_2SO_4 are probably beneficial in Ni plating any type of die casting. The following formula for the

castings resulting in a high luster without polishing is. H_2O 1 gal., single Ni salts 12 oz., boric acid 1.5 oz., anhyd. Na_2SO_4 12 oz., NH_4Cl 2 oz.; *brightening agent*, Cd sticks or 5 grains CdCl_2 per gal. of soln. The p_{H} of this soln. should be 5.4, acidulating with HF, temp. 27° , voltage 4–5, anodes 99% Ni, current 10–25 amp./sq. ft. of surface. MgSO_4 can be used in place of Na_2SO_4 , giving a whiter plate. The following formula was used successfully: H_2O 1 gal., MgSO_4 12 oz., single Ni salts 12 oz., boric acid 2 oz., NH_4Cl 2 oz., acidulating with HCl , p_{H} 5.4, brightening agent CdCl_2 . The following formula for electrolytes is also suggested: H_2O 1 gal., single Ni salts 32 oz., CoCl_2 4 oz., MgSO_4 16 oz., boric acid 2 oz., AcOH 0.5 oz.

The production of metal coatings on Fe (KRÖHNKE) 9. Use of the Hg cathode in anodic oxidation processes (SCHERBAKOV) 2.

WOODRUFF, L. F.: *Principles of Electric Power Transmission and Distribution*. New York: John Wiley & Sons, Inc. 340 pp. \$4.00.

5—PHOTOGRAPHY

C. E. K. MEES

Photochemistry of silver iodide. LÜPPO-CRAMER. *Phot. Ind.* 1925, 1116–7, cf. C. I. 19, 1382.—AgI in gelatin, when sensitized with metol and sulfite, as in the Johnson process, prints out more strongly than when treated with sulfite alone, yet it is more sensitive for development when treated with sulfite alone than with metol plus sulfite. C. is unable, by any means of sensitizing or ripening, to obtain a AgI emulsion of speed even equal to that of a bromide lantern plate. In the case of some iodide emulsions prep'd, he observed an apparent increase in sensitivity by the action of CrO_3 soln. This was found to be due to the action of the H_2O alone, followed by drying; and is attributed to an effect of the swelling and drying of the gelatin on the AgI grain. C. E. K. M.

Photographic sensitometry. A. ODENCRANTS. *Phot. J.* 65, 191–3 (1925).—O. used a 10-volt, 0.5-watt lamp, with filter, and controlled voltage to 0.2%. If 2 curves are plotted, one with the time scale, and the other with the intensity scale, the time scale will fall above the intensity scale. The difference is the Schwarzschild const., which varies with time, temp., developer and probably, gamma. In plate testing, the intensity curve is the most important, the variations being obtained by use of a Sanger-Shepherd step-wedge, which does not require great intensity. O. used 2 different solns. for developing, first soaking the plate in a reducer, and then in the alk. soln., finally stopping development by a rinse in $\text{HC}_2\text{H}_3\text{O}_2$. He recommends that a density curve be given for (1) a standard developer, (2) for process plates with a constant developer, and (3) with the manufacturer's formula, and advises the use of the intensity scale in plate testing.

M. A. YERGER

Enhancing the sensitivity of papers by optical sensitizing. K. JACOBSON. *Phot. Ind.* 1925, 1127–8.—By bathing fast papers, as used for enlarging, in a 1 in 1,000,000 erythrosin soln. to which 2 drops of NH_3 per 100 cc. has been added, for 2 min., washing for 3 min. in change of H_2O , and drying, J. obtains an increase in speed to 2–4 times. The paper may be developed by bright red light, or alternatively by a yellow safelight if a little pinakryptol green be added to the developer. Pinachrome instead of erythrosin increases the speed up to 15 times, but renders the paper red-sensitive and also increases the rate of development, so that it is not easy to avoid fog. C. E. K. M.

Optical sensitizing. II. G. KÖGEL AND A. STEIGMANN. *Phot. Ind.* 1925, 1169–70.—These facts support the generalized photochem. hydrogenation-dehydrogenation theory: Methylene blue is hydrogenated by neoarsphenamine even in the dark; eosin is not hydrogenated in the dark, even on warming, but almost instantly in sunlight or in the light of a quartz lamp, the color returning almost as quickly in the dark unless the insolation has been unnecessarily prolonged; in this case the eosin is irreversibly changed into a strongly fluorescing substance. Instead of neoarsphenamine, hyposulfite, alk. arspenamine, arsenophenylglycine, or Na_3AsO_3 may be used as bleach-out sensitizer.

C. E. K. M.

What do we mean by light-sensitivity? A. STEIGMANN. *Camera (Luzern)* 4,

97-100(1925).—The light-sensitivity of substances has been largely measured by the visible effects produced in photographic processes. These effects, however, are dependent upon both light and dark reactions, the nature of the developer, the complex nature of the sensitive surface, etc. This point is illustrated by the discovery by Shepard of the influence of substances like allylthiourea on the sensitivity of AgBr. What is needed is a true criterion of the inherent light-sensitivity of substances, and an understanding of the conditions on which it depends. Investigation in the field of org. photochemistry will help solve the problems of the photochemistry of the Ag salts. For example, allylthiourea has been found by Kögel and Steigmann to be one of the best sensitizers for bleach-out dyes. The optical sensitizing and desensitizing of Ag salts has also been explained on the basis of org. photochemistry. Under the influence of light certain dyes are assumed to be capable of activating labile H atoms (e. g., in allylthiourea). If this H is taken up partly by the dye, and partly by the Ag halides, with reduction of the Ag salt, optical sensitizing takes place; if the H (which may also be activated by AgBr, or finely divided Ag) is taken up exclusively by the dye, desensitization takes place. M. W. SEYMOUR

Remarks on measurement of densities in parallel light. W. SCHEFFER. *Phot. Ind.* 1925, 1093-4.—Using a Martens photometer under suitable divergent conditions, S. has made comparative measurements of photographic densities in parallel light and in light approaching a numerical aperture of unity. He finds that the steeper gradation in parallel light becomes less marked the finer the grain of the deposit. C. E. K. M.

Measurement of photographic densities. F. C. TOY. *Phot. J.* 65, 164-77(1925).—A sketch is given of work on photographic densities, beginning with the attempts of Hurter and Driffield and Abney (1890). Because of the complexities of the problem it is unlikely that an accepted standard visual method for measuring printing value of photographic densities will be reached. Printing density is defined and a statement made of the variables: (a) printing light; (b) printing medium. Details are given for carrying out the actual measurements. Variation in printing intensity and time of exposure has no effect on printing densities (D_ϕ). The value of a printing density is independent of the kind of plate or paper used in its detn. The effect of quality of light was detd. by varying the voltage on the printing lamp and using a green filter. Little variation was found in printing density. An expression is developed giving the relation between projection densities (D_H) and printing densities (D_ϕ), $D_H/D_\phi = 1 - (1/D_\phi) \log(1-f)$, where f is the fraction of light scattered by the negative being measured. The equation $D_H = kD_\phi$ satisfactorily expresses the relation between printing density and density measured with diffused light for higher values. It is in error in measuring low densities. M. A. YERGER

Photographic development. Measurement of densities and the interpretation of results. F. F. RENWICK. *Phot. J.* 65, 188-9(1925).—R. recommends that a manufacturer should designate the details of development suitable for a given material and that all plates for portraiture should be compared at a gamma of 0.6-0.8 and 0.9-1.1 for plates for general work. Density measurements should be made with diffused light, the diffusing medium being an accepted standard material. The objection is made that the H. & D. system devotes attention only to the straight portion of the characteristic curve, consideration of threshold exposure values being omitted. M. A. Y.

Development in bright light. A. HÜBL. *Phot. Rund.* 62, 461-4(1925); cf. *C. A.* 20, 153, 555.—Desensitizers behave differently with different developers. Pinakryptol green and phenosafranine are insol. in hydroquinol developers and sol. in glycine, metoquinone or elon-hydroquinol when the ratio of elon to hydroquinol is 2:1, or more. Used as a preliminary bath the desensitizer sometimes accelerates development and sometimes retards it. An energetic amidol developer loses its rapidity while a slow hydroquinol developer is accelerated. V. MOVES

Divided development. P. VON JOANNOVICH. *Phot. Ind.* 1925, 1176-8.—After bathing for 1 min. in a soln. of metol 5, hydroquinol, 5, Na₂SO₃ 100, H₂O 1000, plates are transferred to 10% K₂CO₃ soln., in which in 30 sec. (or a few sec. less or more) development is complete. The first soln. may be used to the last drop, but the second must be renewed after about 30 plates have passed through it. C. E. K. M.

P. P. v. Veimarn's opinions on the states of matter in their application to the photographic ripening and development processes. A. SREIGMANN. *Camera (Luzern)* 4, 66-9(1925); cf. *C. A.* 19, 1668.—Fine, highly dispersed crystals may be obtained by mixing either an extremely dil. soln. of NH₃-free, KBr gelatin and AgNO₃ gelatin, or a very concd. soln. of these salts. Large crystals cannot form from the dil. soln. because of the lack of dissolved material; nor from the concd. soln. because of the very slight solv. of AgBr in H₂O and the spontaneous formation of an immense no. of nuclei. Only the

second method is of practical value in the prepn. of emulsions. The use of NH_3 favors the formation of larger crystals by increasing the soly. of AgBr , and thereby reducing the no. of nuclei. Slow mixing and the use of KBr favor the formation of large crystals. The addition of KI favors the formation of smaller crystals and more light-sensitive emulsions. The mechanism of the action of the iodide is explained in detail. S. has developed a means of detecting the presence of $1/40$ mg. of colloidal Au and 1 cu. m. of H_2O , based upon the ability of colloidal Au to catalyze the reduction of certain soln. of Ag salts. The Ag nuclei of exposed plates may be analogously detected by the use of Lumière's intensifier. The difference in the dispersity and color of the Ag deposits on chemically and physically developed plates is explained on the basis of the degree of supersatn. with respect to Ag occurring in the 2 kinds of developing soln.

M. W. SEYMOUR

Interpretation of results of photographic plate tests. O. BLOCH. *Phot. J.* 65, 186-7(1925).—B. notes the important factors that must be considered in making various kinds of photographic plates and points out the characteristics which may be analyzed with the small data.

M. A. YERGER

The prevention of graininess in small negatives. A. STEIGMANN. *Camera (Luzern)* 4, 91-2(1925).—Care must be exercised in the choice of the negative material. The best materials are to be found among plates and films of medium sensitiveness. The use of a pyro developer is recommended, since the oxidation products of the pyro tend to surround the Ag grains, and to prevent development spreading to proximal grains.

M. W. SEYMOUR

New experiments on the effect of color filters. F. FORMSTECHE. *Phot. Rund.* 62, 467-8(1925).—In the printing-out process the use of a yellow filter made from auramine increases the contrast of the image, especially in the middle tones, while the finished picture shows a bluer tone, which is more permanent than the usual red one. A red filter of Ponceau 2R gives soft pictures with a greater tone scale. A green filter produces less than normal contrast but more contrast than the red filter. A blue filter increases contrast and gives a bluish image.

V. MOYES

Effect of a yellow filter on the printing of printing-out paper. M. MÜNZINGER. *Phot. Ind.* 1925, 1094-6.—While AgCl in presence of AgNO_3 has a single sensitivity max. in the near ultra-violet (at about $375 \mu\mu$), the same material after printing out to a rose to violet colored "photo-chloride" has in addition another max. in the yellow-green, thus explaining the steeper gradation obtained by printing under a yellow or green filter.

C. E. K. M.

Palladium toning. F. FORMSTECHE. *Camera (Luzern)* 4, 70-2(1925).—Pd toning is used mostly in combination with Au toning. The chief difficulty with Pd toning is a yellow stain over the whites, consisting of PdS . This is caused by the fact that the AgNO_3 cannot be completely washed out of the print before toning. AgNO_3 and PdCl_2 give $\text{Pd}(\text{NO}_3)_2$, which is hydrolyzed to insol. $\text{Pd}(\text{OH})_2$. $\text{Pd}(\text{OH})_2$ is converted into PdS by "hypo." One remedy is to use NH_4Cl instead of "hypo" for fixing. Another remedy is to ppt. the Ag in the paper by inserting a NaCl bath before toning. This method makes toning slow, and gives yellowish brown tones. These may be avoided by using a Au bath for a short time before the Pd bath. Pure Pd toning is recommended for buff papers only.

M. W. SEYMOUR

Oxidation fog. PATHÉ-CINÉMA. *Bull. soc. franç. phot.* 67, 28-9(1925); cf. C. A. 19, 1384.—Observations of Dundon and Crabtree on the effect of desensitizers, particularly pinakryptol green, in preventing oxidation fog with developers have been confirmed. The desensitizer, basic scarlet N, when added to an elon-hydroquinol developer in the proportion of 1 g. of dye to 1000 l. of developer, is effective in preventing aerial fog.

J. I. CRABTREE

Action of photographic fixing baths and their components on various metals. I and II. M. EULE. *Phot. Ind.* 1925, 1244-5, 1273-4.—The metals tested for their action on fixing baths were Pb , Cu , Sn , Al , Zn , brass and nickel-plated brass. These, in the form of rectangular strips, were immersed, at room temp. for about 40 days, in each of the following solns.: (1) "hypo" 20%; (2) Na_2SO_3 50 g., H_2SO_4 6 cc., H_2O 1 l.; (3) soln. 2 in which 200 g. of hypo per l. had been dissolved; (4) a used fixing bath contg. 20% of hypo, a little H_2SO_4 , and 3.19 g. of Ag per l. The amt. of metal depositing as oxide or sulfide, or passing into soln., and the Ag displaced from the used bath, were compared, and the results summarized in 2 tables. Al , Sn and Pb are, in the order named, the metals least attacked by the fresh acid fixing bath.

C. E. K. M.

Fixing baths and fixing times. E. KARGE. *Phot. Ind.* 1925, 1319-22.—The rate of fixing of Agfa cine positive film is greater in an $(\text{NH}_4)_2\text{S}_2\text{O}_8$ than in a $\text{Na}_2\text{S}_2\text{O}_4$ soln. of corresponding S_2O_4 content, and the optimum concn. in each case corresponds to

about 16% S_2O_3 . In an iodide-contg. emulsion this optimum concn. is higher, fixing is slower, and the superiority of the $(\text{NH}_4)_2\text{S}_2\text{O}_3$ is relatively more marked.

C. E. K. M.

Improvements and simplification pertaining to the dichromated gum process. C. DUVIVIER. *Camera (Luzern)* **4**, 59-63, 88-90, 117-20(1925).—The 2 principal modifications which D. has introduced into the dichromated gum process for making prints are: (1) That the gum and the coloring matter are added, in powdered form, to the soln of $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$; (2) the prints are allowed to "ripen" for 24 hrs. after exposure and before development, whereby the action produced by the light is increased. Full directions are given for carrying out the process according to the method of D.

Interpretation of the H. and D. curve. T. T. BAKER. *Phot. J.* **65**, 181-5(1925).—General summary of the views of various leading workers.

M. A. YERGER

Red filter in the printing-out process. F. FORMSTECHE. *Phot. Ind.* **1925**, 1119.—The use of a red filter of Ponceau 2K in gelatin diminishes the contrast obtained with printing-out paper considerably. In consequence of the color adaptation, the color of the print is a striking crimson. This disappears for the most part in toning and fixing, the loss of density being greater than when no filter is used, so that considerable overprinting is required.

C. E. K. M.

Washing motion picture film. K. C. D. HICKMAN. *Trans. Soc. Mot. Picture Eng.* No. **23**, 62-73.—Motion picture film loses "hypo" exponentially in a rapid stream of H_2O . The actual rate of washing under practical conditions depends on 3 factors: nature and degree of swelling of the emulsion; the rate of stirring of the H_2O ; and the rate of renewal of H_2O in the washing vessel. Washing takes place most efficiently when the rate of diffusion from the film is equal to the rate of diln. in the vessel. As this requires that the H_2O be changed every 0.5 min. such a condition is impracticable. Washing by "changes" or in "cascade" can be made to give rapid washing, especially if vigorous stirring is employed. The nature of town water supplies, the effects of high temps. and partial washing in sea water are examd. The theoretical advice is reinforced in the practical recommendations.

A. R. MIDDLETON

Proposals of the German Nomenclature Committee for Inorganic Chemistry. R. J. MEYER AND A. ROSENHEIM. *Z. angew. Chem.* **38**, 713-5(1925).—A preliminary report.

AUSTIN M. PATTERSON

Antimony sulfides. L. M. CURRIE. *J. Phys. Chem.* **30**, 205-38(1926).—Pptd Sb sulfides, Sb_2S_3 and Sb_2S_5 , are amorphous solids. All the amorphous products are converted into black cryst. Sb_2S_3 by long heating at approx. 200° . Amorphous Sb_2S_3 in a very fine state of subdivision is yellow while larger particles are crimson; intermediate shades contain particles of intermediate size or are mixts. of yellow and crimson. Maroon shades are mixts. of crimson and black sulfides. A cryst. yellow Sb_2S_3 can be found by elec. disintegration of stibnite under H_2O . Pigments pptd. in the presence of S'' or HS' will not darken through crimson and maroon shades but instead darker through varying shades of golden to brown and then to the black modification. The difference between the brown and maroon pigments is due to an adsorbed film of H_2S by the former which prevents growth of the particles. Cryst. crimson pigment has not been prepd.

HARRY B. WEISER

An investigation of the green color of tungstic oxide. NICOL H. SMITH AND HIRAM S. LUKENS. *Chem. News* **132**, 33-5(1925).—Samples of WO_3 , varying in color from light to dark green did not change in wt. or in color when heated in a current of O . All green samples contained Na salts, whereas yellow oxides contained only traces. Furthermore addn. of Mn or Fe compds. in the prepn. of the yellow oxide did not give a green product on ignition. Ignited green WO_3 on being dissolved in NH_4OH and reprecipd. with acid gave a yellow oxide free of Na salts. On the other hand the depth of green could be controlled in the prepn. of the WO_3 by the concn. of the Na_2WO_4 treated with acid and therefore by the amt. of Na compds. in the final product. It was thus proved that the green color of WO_3 is due to Na compds. and that the depth of color varies with the amt. Light does not turn yellow WO_3 to green WO_3 , and in fact it has,

contrary to the view of v. Liempt (*C. A.* **16**, 880), no part in the phenomena described. During the evapn. of a soln. of $(\text{NH}_4)_2\text{WO}_4$, NH_4Cl , NH_4OH and NaCl , a white cryst. Na-NiI_4 complex of the compn. $10\text{WO}_3 \cdot 4\text{Na}_2\text{O} + 4(10\text{WO}_3 \cdot 4(\text{NH}_4)_2\text{O}) + 50\text{H}_2\text{O}$ was obtained (cf. Gibbs, *Am. Chem. J.* **1**, 229(1879)). On ignition it first became yellow and then intense green, the latter color arising from the presence of Na compds. which could not be extd.

C. C. DAVIS

Some double fluorides of zirconium. M. M. WINDSOR. *J. Am. Chem. Soc.* **48**, 310-2(1926).—The following 6 new double fluorides of Zr were prepd. by dissolving ZrO_2 in HF, adding an equiv. amt. of the base in EtOH and either crystg. or pptg. with Me_3CO : *aniline (A) deriv.*, $\text{A}_2\text{H}_2\text{ZrF}_6 \cdot \text{H}_2\text{O}$; *brucine (B) deriv.*, $\text{B}_2\text{H}_2\text{ZrF}_6 \cdot 7\text{H}_2\text{O}$; *cinchonine (C) deriv.*, $\text{CH}_2\text{ZrF}_6 \cdot 2\text{H}_2\text{O}$; *quinine (D) deriv.*, $\text{D}(\text{ZrF}_6)_2$; *quinidine (E) deriv.*, $\text{E}(\text{HIZrF}_6) \cdot \text{ZrF}_6 \cdot 4\text{H}_2\text{O}$; *strychnine (F) deriv.*, $\text{F}_3(\text{HIZrF}_6)_2 \cdot 2\text{H}_2\text{O}$. All were white and transparent when dry and were sol. in EtOH and in hot and cold H_2O . A double fluoride with cinchonidine could not be crystd. from the impure jelly first obtained. In the prepn. of the aniline deriv., a red cryst. compd. was obtained which was probably a double fluoride of some oxidation product of aniline, contg. 29.87% F and 32.68% Zr. Solns. of the quinidine deriv. were bluish and opalescent. These compds. should be of value in the development of a method for the sepn. of Zr and Ti similar to that of Schaeffer (*C. A.* **3**, 519) for the sepn. of Ti from Co and Ta.

C. C. DAVIS

Tellurium nitride. WILHELM STRECKER AND WERNER LEBERT. *Ber.* **58B**, 2527-34(1925).—Tellurium nitride, Te_3N_4 , was prepared in the form of deep yellow amorphous fragments by the action of liquid NH_3 on TeCl_4 or TeBr_4 , at -15° to -70° , in the complete absence of H_2O . The complete reaction would be, $3\text{TeBr}_4 + 16\text{NH}_3 = \text{Te}_3\text{N}_4 + 12\text{NH}_4\text{Br}$. This reaction is an ammonolysis and in practice does not go to completion, so that the Te_3N_4 is mixed with small amts. of ammonobasic salts, e. g., $\text{Te}_3\text{Br}_5\text{N}_2$. The NH_4Br was removed from the reaction products by repeated extn. with liquid NH_3 . Te_3N_4 explodes violently upon slight mechanical shock and when touched by Br or H_2SO_4 , or when dropped into Cl_2 gas. When moist with liquid NH_3 it is only slightly explosive. It is decompd. by H_2O . The compn. suggested for Te_3N_4 is, $\text{N} \equiv \text{Te} - \text{N} = \text{Te} = \text{N} - \text{Te} \equiv \text{N}$. The compd., TeN , described by Metzner (*Ann. chim.* **15**, 257-63 (1898)) as the product of the above reaction, is not formed.

R. H. LOMBARD

Correction to a paper on aluminum sulfide. WILHELM BILTZ. *Z. anorg. allgem. Chem.* **146**, 289-90(1925); cf. *C. A.* **5**, 3019, 3661.—The colorless, needle-like crystals that appeared during the sublimation of Al_2S_3 have been identified as SiS_2 .

R. L. DODGE

Metal-carbon monoxide salts. XII. The behavior of carbon monoxide toward palladium salts and platinum salts; and a separation of palladium and platinum based thereon. W. MANCHOT. *Ber.* **58B**, 2518-21(1925); cf. *C. A.* **19**, 942.—Dry or moist PdCl_2 does not form compds. with CO at 260° . The compds., $\text{PdCl}_2 \cdot \text{CO}$, $\text{PdCl}_2 \cdot 2\text{CO}$ and $2\text{PdCl}_2 \cdot 3\text{CO}$, reported by Fink (*Compt. rend.* **126**, 646(1898)) in sublimates obtained by the action of CO on PdCl_2 at 260° , were the analogous compds. of Pt which were present in the PdCl_2 as impurity. Small amts. of Pt in Pd can be detected or detd. and Pd can be freed from Pt as follows: Pass dry CO over the dry mixt. of PdCl_2 and PtCl_2 at about 250° so long as a sublimate of the CO compd. of Pt continues to form. Wash the sublimate from the tube with H_2O and aqua regia, evap., ignite and weigh as Pt, Ru, Rh and Os, if present, will also be in the sublimate in the form of their CO compds. CO reduces PdCl_2 rapidly in aq. soln., but in H_2SO_4 or fuming HCl soln. there is no reduction until 20 and 10% H_2O , resp., are added; and there are no compds. formed. The relative stabilities of the CO compds. of the metals of the Pt group are discussed.

R. H. LOMBARD

Researches on stannous chloriodide, bromiodide, and chlorobromide. T. KARANTASSIS. *Compt. rend.* **182**, 134-6(1926).—I dissolved in a HCl acid soln. of SnCl_2 gives a red soln. which becomes pale yellow upon reduction by tin plate in excess. On cooling needles of SnClI are obtained. The crystals are colorless and unstable in moist air. Their compn., checked by thermal analysis, corresponds to that calcd. for SnClI . SnBrI is obtained in soln. by reducing a soln. of SnBr_2 , HBr and I with tin plate. Analysis of the crystals indicated a solid soln. of SnI_2 in SnBrI . SnBrCl cannot be obtained in a wet way because of its great soly. In a dry way, SnBr_2 and SnCl_2 give a mixt. that swells greatly during crystn. but no stable mixed salt results. These results differ from those of Young and Maxwell (*J. A. C. S.* **9**, 515(1897)).

7—ANALYTICAL CHEMISTRY

WILLIAM T. HALL

The purposes and aims of agricultural chemical analysis. C. A. BROWNE. *J. Assoc. Official Agr. Chemists* 9, 15-23(1926).—An address. A. P. C.

The reliability of qualitative analytical procedures in the hands of beginning students. G. B. HEISIG. *J. Chem. Education* 3, 177-88(1926). E. J. C.

Critical remarks about iodometric methods. M. BÖTTGER. *Chem. Umschau Fette, Öle, Wachse u. Harze* 32, 275(1925).—Possible titration errors in the reaction between As_2O_3 , HCl and iodides were investigated. Atm. O_2 may cause greater pptn. of I than light, especially when the titration is made after fixed time intervals, but even immediate titration may cause high results and the end point may become indefinite by re appearance of the blue color. Standardization of the oxidizing agents must be made with I ions to obtain correct results; a direct oxidation of the $Na_2S_2O_3$ soln. as in the back titration of its excess may cause partial conversion into sulfate. $K_2Cr_2O_7$ gives correct values only when air is excluded. P. ESCHER

The use of uranous sulfate in volumetric analysis. G. VORTMANN AND F. BINDER. *Z. anal. Chem.* 67, 269-76(1925).— $U(SO_4)_2$ is fairly stable in aq. soln. toward atm. oxidation and is not oxidized readily by H_2O_2 and I_2 . Ferric salts are reduced quickly but molybdates are not. $U(SO_4)_2$ is, therefore, a moderately strong reducing agent which can be used for the titration of trivalent Fe in the presence of molybdic acid and for the indirect titration of substances which are capable of oxidizing ferrous Fe. To prep. the standard soln. dissolve 50 g. UO_2SO_4 in 200 cc. of water, make strongly acid with H_2SO_4 and reduce on the hot water bath with granulated Zn. Dil. the soln. to make it approx. 0.1 N and standardize against $KMnO_4$. Kept in the dark, the titer of a soln. changed to about 0.75 of its original value after standing 26 days. Procedures are given for the titration of ferric salt, evaluation of pyrolusite, detn. of HNO_3 , $HClO_3$ and H_2CrO_4 . The results given are accurate to about 0.5%. W. T. H.

Critical studies on the fusion of rare metal ores. II. The separation of tantalum and columbium. GEO. W. SEARS. *J. Am. Chem. Soc.* 48, 343-8(1926); cf. C. A. 19, 2000.—The sepn. of Cb and Ta is based on the difference in decompn. temps. of Na tantalate and columbate, and on the difference in soly. of the compds. formed. The ore is fused with $Na_2S_2O_7$ at 835-875°, leached, filtered and the residue washed with 3 N HCl. Conc'd. H_2SO_4 dissolves out the Cb compd., leaving the insol. Ta oxide.

ALBERT THOMAS FELLOWS

A new method of separation of iridium from rhodium and platinum and the separation of platinum and rhodium. ISABURO WADA AND TAMAKI NAKAZONO. *Sci. Papers Inst. Phys. Chem. Research* 1, 139-54(1925).—Rh and Pt are reduced to metal by $Ti_2(SO_4)_3$, but Ir is not. The Ir can be pptd. as sulfide in the remaining soln. and sepd. from the Ti. To the soln. contg. chlorides of Ir, Rh and Pt add $Ti_2(SO_4)_3$ soln. and after 5 minutes filter off the reduced Rh and Pt, washing first with 2 N H_2SO_4 and then with water. To the filtrate add an equal vol. of glycerol or 30 g. of tartaric acid for each 100 cc. of soln. (to prevent hydrolysis of Ti^{++}) and sat. with H_2S in the cold. Stopper and heat an hour in the water bath. Filter, dissolve the sulfide in aqua regia, evaporate to dryness, dissolve in conc'd. HCl and again evaporate to dryness. Repeat the evaporation with conc'd. HCl and finally dissolve the last residue in a few drops of 6 N HCl. Sat. with powdered NH_4Cl and with Cl_2 and allow to stand 30 minutes. A black crystalline ppt. shows that Ir is present. The presence of Ir can be confirmed by heating the HCl soln. contg. Ir with 1 cc. of conc'd. H_2SO_4 , evaporate to fumes and adding powdered NH_4NO_3 in small portions. A blue color should develop. For the Rh and Pt tests, treat the ppt. produced by the $Ti_2(SO_4)_3$ reduction with aqua regia and if a black residue remains, Rh is present. For the Pt test, evaporate the aqua regia soln. to dryness, dissolve the residue in a few drops of 6 N HCl and rinse the soln. into a test tube. Add a strip of Al and allow to stand 20 minutes. A black residue indicates Pt, Ir or both. Fuse the residue with $K_2S_2O_7$, cool and extract with water. A black residue indicates Pt. To detect traces of Pt and Ir, treat the aq. soln. of the pyrosulfate melt with H_2S and sat. with H_2S in the cold. Stopper and heat on the water bath. Cool, filter, dissolve in aqua regia and evaporate to dryness twice with HCl to remove all HNO_3 . Dissolve the residue in a very little HCl, add 1 cc. of alc. and nearly sat. with NH_4Cl . A small yellow ppt. of K_2PtCl_6 indicates Pt and a red soln. Rh. W. T. H.

Standardization of hydrochloric acid against potassium iodate compared with results obtained against soda and borax. I. M. KOLTHOFF. *Pharm. Weekblad* 63, 37-48(1926).—For standardization of 0.1 N HCl, dissolve 0.3566 g. KIO_3 in 100 cc.

H₂O, add 0.5 g. KI and 3 g. Na₂S₂O₃ and titrate with acid, using methyl red as indicator. No color change is obtained until all the KIO₃ is reduced. Titrations by this method check closely with those performed with Na₂CO₃ or borax. Anhyd. Na₂CO₃ is not recommended as a standard since it is hygroscopic and the end point to dimethyl yellow is not sharp when the CO₂ is boiled off. Borax is preferable to Na₂CO₃ on account of its high equiv. wt. and its sharp end point to methyl red and dimethyl yellow. The titration confirms the at. wt. of 10.82 for B. A. W. DOX

Determination of bismuth and its separation from lead and other metals by hydrolysis. LUDWIG MOSER AND WLADIMIR MAXYMOWICZ. *Z. anal. Chem.* 67, 248-56 (1925).—The hydrolysis of Bi salt takes place quantitatively with about 2 g. of KBrO₃ in dil., nearly neutral soln. by slowly adding about the same wt. of KBr in a concd. aq. soln. On boiling off the liberated Br₂, all of the Bi is pptd. The reaction is of the same order to sensitiveness as the test for Bi by means of the sulfide ion. W. T. H.

Determination of thallium. W. STRECKER AND P. DE LA PEÑA. *Z. anal. Chem.* 67, 256-69 (1925).—Five methods were found satisfactory for the detn. of Tl. (1) Ppt. the Tl as NaTl₂Co(NO₂)₆ by means of freshly prepd. Na₃Co(NO₂)₆ and weigh the ppt. after drying at 110°. (2) Ppt. Tl by means of Mg in a flask provided with a Bunsen valve. After all the Tl is pptd., add NH₄Cl soln. and heat till all the excess Mg has dissolved. Dissolve the pptd. metal in HCl and measure the vol. of liberated H₂. (3) Same as (2) but heat the Tl sponge to 200° in H₂ and weigh as Tl. (4) Same as (2) but add some Woods' metal, which in the hot soln. will alloy with the Tl in a form convenient for weighing. (5) Ppt. the Tl as TlI by adding a known vol. of KI soln. and titrate the excess iodide with thiosulfate after oxidation to I₂ by means of HNO₃. W. T. H.

Micro-iodometric determination of copper. N. SCHOORL AND H. BEGEMANN. *Rec. trav. chim.* 44, 1077-86 (1925).—Details are given of a method suitable for the detn. of Cu in the blood of invertebrates, such as snails. The method is based on that given in Pregl's book and depends on (a) destruction of org. matter and conversion of Cu to CuSO₄ by treatment with HNO₃ and H₂SO₄, (b) deposition of Cu electrolytically, (c) soln. of the deposit in HNO₃ and (d) titration with Na₂S₂O₃ of the I₂ liberated when Cu⁺⁺ reacts with KI. E. J. WITZEMANN

The method of Feigl for the determination of copper. F. AZZALIN. *Ann. chim. applicata* 15, 373-7 (1925).—Though the method of Feigl (*C. A.* 18, 30) is claimed to be accurate even with other metals present, tests show it to be very unreliable. Excess benzoin monoxime cannot be completely washed from the ppt., and because of this the method is quicker and much more accurate if the ppt. is incinerated and weighed as CuO. Under these conditions, however, there is a great tendency to form graphite and this cause of high results is avoided only by heating very slowly. With this precaution the method is practically as accurate as standard ones, provided that Cu alone is present. But when Fe, Zn, Al, Pb or Sn is also present, systematic expts. show that even with the most careful technic the error increases progressively with the amt., because of occlusion in the Cu benzoin oxime ppt. The method is in general inaccurate if small amts. of a second metal are present, and is useless with larger amts. C. C. DAVIS

The nephelometric determination of calcium and magnesium. L. KRISS. *Biochem. Z.* 158, 203-4 (1925).—In the presence of NH₄ salts, Mg gives no cloud with Na sulfocinoleate (*C. A.* 17, 3351). Ca, therefore, can be detd. nephelometrically with this reagent. F. A. CAJORI

Two methods for the separation of lead and silver. G. VORTMANN AND O. HECHT. *Z. anal. Chem.* 67, 276-9 (1925).—If (NH₄)₂HPO₄ is added to a slightly ammoniacal tartrate soln. contg. Ag and Pb ions, the latter are pptd. as Pb₃(PO₄)₂. The ppt. can be filtered off and weighed after gentle ignition. If KI is added to a slightly ammoniacal soln. contg. Ag and Pb in the presence of an excess of tartrate ions, the Ag ions are pptd. as AgI which can be weighed. For 0.5 g. of the metals, 2.5 g. of tartaric acid should be used before adding NH₃ in the latter sepn. W. T. H.

Estimation of iron by reduction with hydriodic acid. F. J. WATSON. *Chem. Eng. Mining Rev.* 18, 80-1 (1925).—Directions are given for carrying out the well-known iodometric method of C. Mohr (*Ann.* 105, 53). L. W. RIGGS

A method for the determination of arsenic. I. BANG. *Biochem. Z.* 161, 195-209 (1925).—Org. material contg. As is oxidized with a HNO₃-H₂SO₄ mixt. The As is then reduced to As₂O₃ by use of FeSO₄, and is converted to AsCl₃ by the addn. of KCl and KBr. If the KBr is omitted, reduction is not complete. The AsCl₃ is then distd. directly into a flask contg. H₂O, is neutralized with NaHCO₃, and titrated with I, with starch as an indicator. W. D. L.

A sensitive differential reaction of cerium. L. FERNANDES. *Gazz. chim. ital.* 55,

616 8(1925) —In the study of the various complexes formed by the rare earth hydroxides and pyrocatechol, pyrogallol and hydroxylated org. compds. (to be described in a later paper) a new sensitive reaction for Ce, even in the presence of the other rare earth elements, was discovered. One part Ce per million can be detected, but in the presence of the other rare earths the reaction is somewhat less sensitive. One part Ce in 400,000 of H_2O is easily detected. A soln. of a Ce salt treated with pyrocatechol and then NH_4OH gives a violet ppt. due to $[Ce(C_6H_4O)_3](OH)_3$ which darkens in the air and which is completely sol. in acids and in strong bases. With NH_4OH the violet salt $[Ce(C_6H_4O)_3](ONH_4)_3$ is formed. By reason of the browning of alk. solns. of pyrocatechol in air the violet color may be obscured unless $Na_2S_2O_3$ is added which delays this browning. The other rare earths give colorless compds. with this reagent. Other elements that give colored compds. with the reagent must be removed before a test is made for Ce.

H. J. WITZEMANN

Sensitive color reactions of zirconium, hafnium and fluorine with hydroxyanthraquinones. J. H. DE BOER. *Rec. trav. chim.* **44**, 1071-6(1925) —Atack (C. A. **9**, 3186) described a color reaction for Al with alizarinsulfonic acid. Lately de B. reported (C. A. **19**, 793) that nearly all rare metals give red to violet color reactions with alizarinsulfonic acid but these all disappear on adding HCl except the red-violet color with Zr, which persists even in the presence of concd. HCl. In 1 cc. contg. enough HCl so that no other metal reacts, 0.02 mg. Zr gives a distinct color. Since they readily form complexes with Zr, F ions disturb the color reaction. Alizarinsulfonic acid is a sensitive reagent for F. 0.02 g. Zr as $ZrOCl_2 + 0.015$ g. alizarinsulfonic acid in 10 cc. H_2O with 60 cc. concd. HCl is a good reagent for F and the red reagent gives a yellow color with 10^{-6} g. F in 1 cc. H_2O . A fairly accurate volumetric method for Zr is described. To the unknown soln. contg. 0.050-0.200 g. ZrO_2 add 15 cc. concd. HCl and 1 cc. of alizarinsulfonic acid soln. Add 1% NaF soln. from a buret until the soln. becomes yellow. Titrate a known soln. in exactly the same way. Repeat the titration with different quantities of the unknown until the blank and the unknown are not more than 0.5 cc. apart on the NaF used. This is done because the NaF required also depends on the HCl present. Most other metals, including Ti, Ce, Er, Yt, Mn, Al, etc., do not interfere. Fe^{+++} must first be reduced with $SnCl_2$; the method fails in the presence of Th. Of the compds. purpurin, rufigallic acid, alizarin blue-S, quinizarin, purpuroxanthin and hystazarin, all those having OH groups in the 1,2-positions (at least) give characteristic colors for Zr as with alizarinsulfonic acid. The results with the other 3 dyes are not similar. The behavior of Hf with these dyes resembles that of Zr. In concd. HCl solns. the color faded somewhat sooner with Hf especially with rufigallic acid. Hf stands between Zr and Th but closer to Zr in this respect since Th gives stronger colorations in almost neutral solns. that fade in even dil. HCl.

E. J. WITZEMANN

Platinum and palladium dimethylglyoximes. R. A. COOPER. *J. Chem. Met. Min. Soc. S. Africa* **25**, 296-7(1925).—Pt dimethylglyoxime forms a fine blue, cryst. ppt. having a characteristic metallic bronze luster when Na formate is added to a slightly acid soln. of H_2PtCl_6 contg. an alc. soln. of dimethylglyoxime. Pptn. is quant. but the compd. cannot be ignited to metal without loss, although it can be dried at 100° to $C_8H_{14}O_4N_4Pt$ for weighing. When NaOH is added to water in which Pt dimethylglyoxime is suspended, it dissolves completely, but an excess causes pptn. of a purple unstable compd.; Pd dimethylglyoxime dissolves in NaOH and is not further affected by excess.

B. C. A.

Methods for the determination of sodium sulfide. P. BUDNIKOV. *Z. anal. Chem.* **67**, 241-8(1925).—Seven well-known methods were studied and satisfactory results obtained except in 1 case in which some H_2S was lost upon neutralizing with AcOH prior to titration with $ZnSO_4$. The method of Podreshetnikov (*Z. Farben. Ind.* **6**, 388) gives good results after a little practice and provides for the detn. of Na_2S and NaSH in 1 operation.

W. T. H.

The reduction of chloric acid and chlorates by ferrous sulfate. CECIL O. HARVEY. *Analyst* **50**, 538-43(1925).—In neutral soln. the reduction is incomplete, better results are obtained in acid soln. but it is advisable to provide a little KI in the analysis of chlorates. The following method gave over 99% of the theoretical value of the oxidizing power. Place 10 cc. of chlorate soln. (0.2 N or less), 25 cc. of acid $FeSO_4$ soln. and 5 g. KI into a glass-stoppered bottle. Tightly stopper and keep in hot water ($45-50^\circ$) for 20 min. Cool, add 50 cc. of recently boiled water and titrate with $Na_2S_2O_3$. Run a blank using 10 cc. of water in place of the chlorate soln.

W. T. H.

Determination of the extract. A new micro method. A. C. RÖTTERING. *Oesterr. Chem.-Ztg.* **29**, 1-4(1926).—The extract, or total solids, of wine, spirits, vinegar, honey solns., etc., is sometimes detd. directly by merely evapg. to dryness and weighing the resi-

due or *indirectly* by detg. the original sp. gr. and that of the soln. after distg. off alc. The direct method as usually accomplished gives reliable results only when the extract is low. By using 0.05–0.2 g. of sample, on a roll of dried filter and heating in an evacuated tube immersed in hot CaCl_2 soln. it is possible to get a very accurate direct detn. of the *extract* or portion non-volatile at 100° .

A method of analysis of colored gas, based on the use of a photoelectric cell and application to the case of nitrous gases. H. COPAUX AND A. COPAUX. *Compt. rend.* **181**, 1058–60 (1925).—The photoelec. cell mentioned in the title is used as a photometer, a column of the gas to be analyzed being interposed between it and a steady light source.

W. T. H.
F. C. KRACEK

Examination of cream of tartar and raw materials containing tartaric acid. FRITZ GLASER. *Z. anal. Chem.* **67**, 279–81 (1925).—The method of Goldenberg (*Z. anal. Chem.* **47**, 57) gives satisfactory results only when all the conditions are kept uniform. The more sensitive the litmus paper used is to acids, the higher the results and the more sensitive to bases, the lower the results. If this method is to be used in cases of dispute, all labs. should use the same litmus paper and keep all conditions as uniform as possible.

W. T. H.

A simple method for determination of nitrobenzene. I. M. KOLTHOFF. *Chem. Weekblad* **22**, 558–9 (1925).—Nitro compds. are reduced to amines by TiCl_3 . Qual test for PhNO_2 : To 10 cc. soln. add 3 to 4 drops 15% TiCl_3 soln. and 1 cc. 4 N NaOH; after 1 or 2 min. make the soln. acid with HCl, add phenol and try the indophenol reaction. The intensity is maximal 3 to 5 min. after addn. of Cl_2 (1:200,000 sensitive). Quant. detn. (a 0.1% soln. nitrobenzene was used): Add to 25 cc. soln. in a glass-stoppered Erlenmeyer flask, 5 cc. 4 N NaOH and 15% TiCl_3 soln. dropwise, until the black remains for 2 min. (flask closed). After 5 min. more, open the flask and shake until all Ti^{++} is oxidized by the air to Ti^{+++} (about 5 min.). Then add 0.5 to 1 g. alkali bromide, 10 cc. 4 N HCl, 25 cc. 0.1 N KBrO_3 , close the flask, after 5 min. add 1 g. KI and titrate back after another 2 min. with thiosulfate. One cc. 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$ corresponds to 2.05 mg. PhNO_2 .

B. J. C. VAN DER HOEVEN

Application of capillary measurements to the study of mixtures of fatty acids. R. DUBRISAY. *Compt. rend.* **181**, 1060–2 (1925).—The author attempts to identify fatty acids by the surface tension of their aq. solns.

F. C. KRACEK

Microchemical identification of metaldehyde. GEORGES DENIGÈS. *Bull. soc. pharm. Bordeaux* **63**, 207–12 (1925).—Place a small quantity of the material (less than 1 mg. is sufficient) on a glass slide, suspend another slide above it and sublime with the aid of a very low flame. The sublimate, when examd. under the microscope, will be found to consist of long, brilliant prismatic needles emerging from the face of the slide and pointing in diverse directions. Below these larger crystals will be found other smaller ones which also are prisms, but which appear to be branched because of their juxtaposition with respect to other similar crystals. If a small quantity of the material is dissolved in CHCl_3 and the latter allowed to evap. spontaneously, the metaldehyde will be deposited in the form of rhombic needles. These are frequently grouped or interlaced in a characteristic manner. To confirm the microcryst. tests, the following color reaction may be applied: Dissolve a little of the material in a droplet of concd. H_2SO_4 and add a small crystal of guaiacol. If the material is metaldehyde, a blood-red color will develop. Other phenols will also give the test.

A. D. DUMÉZ

Detection of small quantities of arsenic in cocoa. H. LÜHRIG. *Pharm. Zentral-halle* **67**, 1–3 (1926).—Mix intimately in a porcelain dish 15 g. of the sample with 0.5 g. MgO and 5 cc. concd. As-free HNO_3 , evap. to dryness on the H_2O bath and carefully incinerate. Treat the ash with As-free HCl, filter, add H_2SO_4 and heat to appearance of SO_3 fumes, cool, add H_2O and test in a Marsh app. The As test may be more expeditiously made *via* Reinsch by treating 15 g. of the sample with 75 cc. As-free HCl (about 16%), immersing a narrow bright Cu foil (1×4 cm.) and boiling gently 20–25 min., cooling and dilg. with H_2O , rejecting the liquid and examg. the Cu strip which in the presence of As (as little as 0.15 mg.) is colored gray. The As may be sublimed by repeated dipping of the foil in fresh H_2O , rolling and gently heating over a micro-flame and under a cooled cover glass.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY

The use of the Skita apparatus in experimental mineralogy. N. NIKOLOFF. *Centr. Mineral. Geol.*, A 1925, 183-91.—Exptl. results on the action of CO_2 solns. on orthoclase, olivine, augite, serpentine, bronzite and diopside are given. The app., briefly described, provides a continuous supply of fresh CO_2 throughout the expt.

J. E. GILL

Dilute coloring of minerals. R. KLEMM AND G. O. WILD. *Centr. Mineral. Geol.* A 1925, 291-5.—The coloring of idiochromatic minerals is probably due to complex structures. Many others are believed to be colored by subsequently sepd. colloidal particles.

J. E. GILL

Coloration of quartz. R. KLEMM AND G. O. WILD. *Centr. Mineral. Geol.*, A 1925, 270-3.—Chem. and spectral analyses show no marked differences between quartzes of different colors. Li and Na are the only foreign elements showing lines in the spectra not present in the spectrum of the electrodes. It is planned to det. whether the coloring is due to Na and Li, or to splitting off of Si from the mol. No reference is made to the work of Holden (*C. A.* 19, 3447) in solving this problem.

J. E. GILL

Spectroscopic investigation of minerals. I. Sapphire. G. O. WILD AND R. KLEMM. *Centr. Mineral. Geol.*, A 1925, 273-4.—Comparison of blue-green sapphire from Anakie, Australia with an artificial stone of the same color showed that both contained Fe and Ti. Colorless sapphire from Ceylon contained no Fe, but CN bands and lines of B, Ge, Ag were present. Blue sapphire from Australia showed Fe, CN and B. II. Beryl containing cesium. *Ibid* 295-6.—A Cs content is typical of rose beryl and is regarded as the coloring agent.

J. E. GILL

Lead sulfobismuthite of volcanic origin. F. ZAMBONINI, O. DE FIORE AND G. CAROBBI. *Rend. accad. sci. Napoli* [iii], 31, 24-9(1925).—A cryst. mineral, for which the name *cannizarite* is proposed, has formed since 1921 in the lower parts of fumaroles on Vulcano (Eolie, Lipari Islands), where the emission of acid volcanic gases is greatest and access of air is prevented. The temp. of the region is 550-615°. The crystallographic const. were not detd. accurately, but the mineral appears to be rhombic, and isogonal with bismuthinite and stibnite in the 001 zone. $d_{100} 6.54$. The analysis corresponds with the formula $\text{PbS}_2\text{Bi}_2\text{S}_3$. It is probably formed by the action at high temps. of H_2S on the chlorides of Bi and Pb.

B. C. A.

Heating curves of Tichvinski bauxites. N. S. KURNAKOV AND G. G. URAZOV. *Ann. Inst. Phys.-Chem. Anal. Leningrad* 2, 495-6(1924).—The heating curve of Ural diasporite exhibits an arrest at 509-555°, but no exothermic effect at a higher temp. Artificial hydrargillite shows 2 arrests, at 200-295° and 509°, resp. After expulsion of the bulk of its water at 100°, colloidal hydrated alumina shows both the diasporite and the hydrargillite arrests. Tichvinski bauxites with high silica contents also show the diasporite and hydrargillite arrests, and, in addn., an arrest at about 567°, corresponding with kaolinite. An exothermic effect at a higher temp. is observed sometimes, but not always.

B. C. A.

Thermal analysis of clays and bauxites. N. S. KURNAKOV AND G. G. URAZOV. *Ann. Inst. Phys.-Chem. Anal. Leningrad* 2, 496-8(1924).—When a pure kaolin $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot n\text{H}_2\text{O}$ (n = about 2), is heated, an endothermic arrest occurs at 558-605° because of the elimination of H_2O and an exothermic effect (recalcination) at 950-1000°. Under identical conditions the cryst. monohydrated alumina, diasporite, shows a temp. arrest at 509-555°, but, like other hydrated forms of alumina investigated, no exothermic effect. The natural trihydrate (gibbsite) or artificial trihydrate is characterized by 2 endothermic arrests on its heating curve, at 202-296° and about 500°, the latter coinciding with that observed with diasporite. With the richly aluminiferous Tichvinski bauxites contg. up to 15% of water and not more than 12-15% of SiO_2 , only endothermic arrest is found corresponding with that of diasporite (509-555°); if the silica exceeds 12-15% the kaolinite arrest (558-605°) also is encountered. The latter bauxites evidently consist of a mixt. of diasporite and kaolinite; further, bauxites contg. more than 14-15% of H_2O exhibit also a lower arrest at 200-296°, indicating the presence of hydrargillite.

B. C. A.

Determination of the plagioclases. ALADÁR AND MIKLÓS VENDL. *Centr. Mineral. Geol.*, A 1925, 177-82.—Useful microscopic data are given. J. E. GILL

Chemical composition of the sanidine from Vegardo. VICTOR ZSIVNY. *Centr. Mineral. Geol.*, A 1925, 279-84.—A discussion. J. E. GILL

The system CaSiO_3 - MgSiO_3 - FeSiO_3 , especially in diallage, augite and hornblende of the gabbro-basaltic magmas. PETER CHIRVINSKII. *Centr. Mineral. Geol.*, A 1925, 199-202.—Av. analyses of diallage, augite and basaltic hornblende suggest 2CaSiO_3 - $3(\text{Mg, Fe})\text{SiO}_3$ as a basic formula for these minerals. MgSiO_3 : FeSiO_3 averages 3:1. This empirical av. formula can be variously interpreted, e. g., as representing diopside, $\text{CaMgSi}_2\text{O}_6$ (77.14 mol. %), with isomorphous mixt. of $(\text{Fe, Mg, Mn})\text{SiO}_3$ (22.8 mol. %) or as an unstable double salt involving the actinolite and wollastonite mols., $\text{Ca}(\text{Fe, Mg})_2\text{Si}_4\text{O}_{12}$. J. E. GILL

The relationship between davynite and hauynite. B. GOSSNER. *Centr. Mineral. Geol.*, A 1925, 169-77.—The minerals have analogous chem. structure plans, are similar in d., n, crystal form, in spite of the fact that they belong to different crystal systems. It is suggested that this similarity be expressed by writing the formulas hauynite $3[\text{Na}_2\text{SiO}_3 \cdot \text{SiO}_2 \cdot \text{Al}_2\text{O}_3] \cdot 2\text{CaSO}_4$; and davynite $3[\text{Na}_2\text{SiO}_3 \cdot \text{SiO}_2 \cdot \text{Al}_2\text{O}_3] \cdot \text{CaSO}_4 \cdot \text{CaCl}_2$. Variations in davynite are small and probably result from partial replacement of Na_2SiO_3 by CaSiO_3 or slight variations in the ratio CaSO_4 : $\text{CaCl}_2 = 1$; some CaCO_3 may also enter. J. E. GILL

Chemical constitution of the gehlenite-melilite group. B. GOSSNER. *Chemie der Erde* 2, 103-13(1925).—The isomorphous mixing of such complex mols. as suggested by Buddington (*C. A.* 16, 1058) is regarded as improbable; and G. traces a connection between the minerals of the gehlenite-melilite group and the monoclinic ("pseudo-tetragonal") pyroxenes. They are regarded as double compds. $\text{CaO} + \text{pyroxene}$, of the form $\text{CaO} \cdot [\text{SiO}_3\text{Ca} \cdot \text{SiO}_3\text{Mg}]$, where SiO_3Mg is replaceable by Al_2O_3 , and $\text{Si}_2\text{O}_6\text{MgCa}$ by $\text{Si}_2\text{O}_6\text{AlNa}$. Gehlenite is written $\text{CaO} \cdot [\text{SiO}_3\text{Ca} \cdot \text{Al}_2\text{O}_3]$ and melilite as $2\text{CaO} \cdot [\text{Si}_2\text{O}_6\text{MgCa} \cdot \text{Si}_2\text{O}_6\text{AlNa}]$. Åkermanite approaches $\text{CaO} \cdot [\text{SiO}_3\text{Ca} \cdot \text{SiO}_3\text{Mg}]$. B. C. A.

Simple stoichiometric relations of the average biotite of granite and the connection between the anorthite and the biotite content of granite. PETER CHIRVINSKII. *Centr. Mineral. Geol.*, A 1925, 304-13.—Av. analyses of biotite in granites suggest that the equl. center for this mineral is an equimolar mixt. of the muscovite and olivine mols. Granites and closely related rock types contain anorthite and biotite in about equal proportions. The anorthite-biotite system in idealized form may accordingly be represented thus: $[\text{CaAl}_2\text{Si}_2\text{O}_8 + \text{CaAl}_2\text{Si}_2\text{O}_8] + [(\text{K, Na, H})\text{Al}_2\text{Si}_2\text{O}_8 + (\text{Fe, Mg})\text{Si}_2\text{O}_6]$. J. E. GILL

Druse minerals in a granite of southern Schwarzwald. ECKART SCHRÖDER. *Centr. Mineral. Geol.*, A 1925, 260-70.—The occurrence and characteristics of biotite, K-feldspar, albite, quartz, molybdenite, pyrrhotite, chalcopyrite, pyrite, tourmaline, zinnwaldite, fluorite, epidote, hematite, prehnite, apophyllite, zeolites, calcite, kaolin and bitumen are described. An analysis of epidote is given. J. E. GILL

Hydrolysis of mica. P. A. ZEMYATCHENSKII. *Ann. Inst. Anal. Physico-Chem. Leningrad* 2, 484-5(1925).—When heated with water, muscovite undergoes energetic hydrolysis and gradually approaches kaolinite in compn. The extent to which this change takes place depends on the duration of the action and on the fineness of the mica; the change may be accelerated and rendered complete by raising the temp. Muscovite is decomposed more readily than kaolinite when treated with 10% HCl soln. Slight hydrolytic decompn. of muscovite doubtless plays a large part in the process of the decay of mica. B. C. A.

Notes on swedenborgite. B. GOSSNER. *Centr. Mineral. Geol.*, A 1925, 289-91.—Similarities in phys. properties and crystal form suggest that swedenborgite consists of an intergrowth of 2 similar corundum-like networks of Al_2O_3 and NaSbO_4 . J. E. GILL

Graphite in Ukraine. V. N. CHIRVINSKII. *Ann. inst. polyt. agr. Kiev* 1924, 61-94; *Mineralog. Abstracts* 2, 557.—Chem. analyses and a bibliography of the Ukraine graphites are given. J. F. SCHAIRER

Barite in Ireland. T. HALLISSY. *Mem. Geol. Survey Ireland, Mineral Resources* 1923, 81 pp.; *Mineralog. Abstracts* 2, 556.—Ba reached the fissures from a deep-seated source and the deposition of BaSO_4 resulted from a reaction between an ascending soln. of BaCl_2 and a descending soln. of sulfate formed by oxidation of sulfides. J. F. S.

The small iodine occurrences in the north German salt deposits. HANS STÖBBE AND K. F. STEINBERGER. *Centr. Mineral. Geol.*, B 1925, 337-40.—Several explanations for the low I content are reviewed. Recent data suggest another theory. Metallic iodides in sea water and in the sap of marine plants become decomposed by atm. CO_2

and photo-oxidation. The I forms tri-iodides or polyhalogen compds., which easily dissociate and give up free I, which volatilizes. J. E. GILL

Coal formation as a tectonic phenomenon. HANS STILLE. *Braunkohle* 24, 913-8 (1926).—A discussion of various European coal deposits from the above standpoint. W. B. PLUMMER

The Secondary [Mesozoic] era and petroleum. A. MONTIBELLI. *Rass. min. met. chim.* 63, 130-2(1925).—The fact that petroleum in Mexico, Roumania and Galicia may be traced to the Mesozoic era led to a study of the westerly basin of Resegone (from Lecco to Maggianico) which is of Lio-triassic formation. The presence of petroleum was further indicated by the presence of feldspar metamorphosed from gabbro in eruptive rock, bituminous shales, rock-salt, waters contg. CaSO_4 and MgSO_4 , sulfurous fluorescent waters, S (perhaps deposited from the action of hydrocarbons on CaSO_4) and emanations of CH_4 . These theoretical considerations were substantiated by the discovery of horizons of petroleum C. C. DAVIS

Quantitative mineral composition of two German gabbros. PETER CHIRVINSKIT. *Centr. Mineral. Geol.*, A 1925, 275-9 —Detns were made by the Rosiwal method, on olivine-gabbro from Volpersdorf, Silesia and amphibole-gabbro from Frankenstein, Odenwald. J. E. GILL

The so-called picrites in Banat. ALADAR VENDL. *Centr. Mineral. Geol.*, A 1925, 297-304.—Petrographic and chem. analyses show that 3 rocks formerly called picrites are actually limburgite, plagioclase-basanite and nepheline-basalt. J. E. GILL

The calcite-rich bombs from the upper Devonian limestone of Oberscheld. ERNA FRERICHS. *Centr. Mineral. Geol.*, A 1925, 161-8 —Petrographic and chem. analyses lead to the conclusion that the calcite-rich volcanic bombs are limestone fragments ejected after metamorphism by a basic magma J. E. GILL

The primary formation of crystalline magnesite. M. ROZSA. *Centr. Mineral. Geol.*, A 1925, 195-7.—Investigations of Paleozoic carbonate rocks have yielded geologic, mineralogic and physico-chem facts which indicate that cryst. MgCO_3 formed as a primary marine sediment. J. E. GILL

The clays of the Lake Agassiz basin. J. E. MAYNARD. *Trans. Roy. Soc. Can., Sec. IV* (3) 18, 103-14(1925).—The paper contains mech., chem. and colloidal analyses of the layers of clay deposited by fresh water in glacial lake Agassiz near Winnipeg. M. claims to have established a relation between hygroscopicity and fineness of grain in the clay particles. Temps from 200° upwards gradually destroy the colloids in the clay until at 1000° they are completely destroyed. J. W. SHIPLEY

Chalk and flint. G. LINCK AND W. BECKER. *Chemie der Erde* 2, 1-14(1925).—An outline is given of the various views on the formation of flint in chalk. Expts were made with solns. of colloidal silica (contg. 0.5-0.8% SiO_2) in the presence of pptd. CaCO_3 (vaterite and calcite). The amt. of silica adsorbed is greater with smaller sizes of grain of the Ca carbonate. Ppts. obtained from solns. of $\text{CaH}_2(\text{CO}_3)_2$ in the presence of sol. silica contain up to 17% SiO_2 , the amt. depending on the concn. of the solns. Treatment of these ppts. after heating at 50 - 200° , with dil. solns. of NaCl , NaOH , NH_3 , etc., causes a portion of the adsorbed silica to pass into soln. again. It can be again coagulated by the action of MgCO_3 or of CaCO_3 soln. in the presence of NaCl . Conclusion: In the formation of chalk the silica was originally distributed throughout the material, as a pellicle around the min. grains of Ca carbonate. There re-soln. of the silica in the presence of alkali and NH_3 from org. remains would leave the CaCO_3 with a loose open texture. Migration and coagulation in cavities and crevices would give rise to nodules, bands, and veins of flint. Analyses of chalk from Rügen show 0.81-1.54% SiO_2 , the amt. varying with the distance from the bands of flint. B. C. A.

Chemical alteration of granite beneath peat. P. BLANCK AND A. RIESSER. *Chemie der Erde* 2, 15-48(1925).—A detailed review and discussion is given of the literature on the formation of clay or kaolin by weathering processes, more particularly in association with peat and lignite deposits. Analyses are compared of fresh granite, from the Harz Mts., and of the weathered rock taken from below a layer of peat and from the surface. There is no evidence of the formation of kaolin under these conditions. SO_2 was found in the weathered products, in peat, sphagnum-moss and moor-waters, and it is concluded that this has some action in the weathering processes. B. C. A.

Weathering of sandstone by circulating solutions. F. KLÄNDER. *Chemie der Erde* 2, 49-82(1925).—The peculiar forms of weathering shown by the sandstones of Saxon Switzerland and the Palatinate are attributed to the action of circulating solns. contg. humus compds. and sulfates derived from the surface vegetation. Analyses are given of the portions extd. by water from the rocks and from the soils derived from them. B. C. A.

Bleached rings and zones containing vanadium in the clay shale of the red beds from the Heinrich shaft, Olsnitz, Erzgebirge. R. SCHREITER. *Centr. Mineral. Geol.*, A 1925, 214-22, 242-50.—Bleached rings, zones and interbeds contain appreciable quantities of V oxides, nuclei of bleached rings having an especially high content. Bleaching results from chem. reactions involving reduction of Fe and oxidation of V.

J. E. GILL

Sources of carbon in the Pre-Cambrian formations. E. S. MOORE. *Trans. Roy. Soc. Can.*, Sec. IV (3) 18, 21-8(1925).—M. reviews the recent discoveries of evidence of plant life in the Pre-Cambrian and describes oölites and concretions of algal origin in the Animiki Fe-bearing rock near Port Arthur, Ontario. Graphitic carbon to the extent of 0.21% was found in the concretions. The occurrence of anthraxolite at Sudbury, Ontario, is attributed to the formation of solid bitumen from oil-producing algae which flourished in the Animiki period.

J. W. SHIPLEY

Origin of terrestrial helium and its association with other gases. S. C. LIND. *Proc. Nat. Acad. Sci.* 11, 772-9(1925).—Review of theories regarding He supports radioactive origin as most probable. The He accumulation of the richest pools requires vertical migration from a depth of only 1 or 2 miles, over a period of 1-2 hundred million years, leaving out of account lateral migration and deep vents. The rarity of these rich He pools is probably dependent on a combination of circumstances favorable to migration and local storage. It is suggested that removal from the radioactive mineral and migration are both aided by the gases generated by certain chem. decomps. produced in the earth's crust by the original high-velocity He atoms (α -rays), such as the decompn. of H_2O , of nitrogenous material, or of carbonates to give CO_2 . Analyses are presented of the gases from 2 samples of uraninite (Katanga and South Dakota) and from 2 secondary minerals (carnotite of Colorado and a mixt. of curite and becquerelite from Katanga). The universal presence of N_2 in uraninite is discussed, as well as the occurrence of O_2 and the low He content of the secondary minerals. The latter is attributed to porosity and the "seeping" effect of the generated gases. The great scarcity of H_2 in natural gases is attributed to catalytic reduction of metallic oxides.

Study of flotation oils applied to the blendes of Ingurtosu. PAUL AUDIBERT. *Rev. ind. minérale* 1926, No. 122, 21-40.—It has already been found that the flotation of Ingurtosu blende is a difficult process, for which pine oil has been used in the past. Lab. expts. with various other oils, including mixts. in different proportions, showed that especially good results can be obtained with the following mixts.: pine oil 50, cresylin 60; crude petroleum 75, pine oil 25; crude petroleum 50, pine oil 50; cresylin 50, Puertollano oil 50; pine oil 50, Diesel oil 50; and pine oil 25, Diesel oil 75. The mixt. pine oil 50, Diesel oil 50 gave the best results of all. This comparison is based on the max. yield of Zn. Calcns., however, of the relative economy showed the mixt. crude petroleum 50, pine oil 50 to be the most economical, followed closely by the mixt. pine oil 50, Diesel oil 50. On an industrial scale, however, a mixt. of pine oil 40, Diesel oil 60 gave the best results. By using excess $CuSO_4$ there was a great economy of oil effected, the amt. being reduced to about $\frac{1}{4}$, and the use of H_2SO_4 eliminated.

Producing gold and arsenic at Jardine, Mont. EDWARD H. ROBIE. *Eng. Mining*

J.-Press 120, 765-72(1925).—An account of the production and treatment of concentrates carrying 38% As and 2 oz. Au per ton. These are roasted to produce As_2O_3 and then shipped to a smelter. A. BUTTS

Manganese and manganiferous ores in 1924. HELENA M. MEYER. *U. S. Geol. Survey, Mineral Resources of U. S., 1924*, Pt. I, 89-103(preprint No. 9, publ. Feb. 3, 1926). E. J. C.

Manganese, its alloys and uses. G. M. DYSON. *Chem. Age (London)* 14, No. 347, Metallurgical Sect. 10-11, 15(1926). E. J. C.

Manganese poisoning and its effect on the central nervous system. R. F. GAYLE. *J. Am. Med. Assoc.* 85, 2008-11(1925).—Mn, more often than is recognized, causes symptoms in workmen handling this ore. Certain persons are not susceptible to the poisoning effects of Mn as encountered in handling the ores. Others are susceptible to the invasion of the central nervous system by this poison and show a gradual progression of the symptoms as long as they absorb Mn ore dust. There appears to be a destruction of cerebral tissue, which, except in the mildest cases, will cause permanent disability. Mental changes were found in each of the 6 cases of this series. Daily baths with change of clothing and the wearing of suitable masks while at work, are suggested as prophylactic measures. L. W. RIGGS

The determination of certain curves and their application to the desilverization of lead by the Parkes process. G. K. WILLIAMS. *Proc. Australasian Inst. Mining & Metallurgy* 1925, No. 58, 47-97.—A study was made of the interdependence of variables in the Parkes process, and also of the possibility of decreasing the quantity of Zn required and raising the Ag content of the crusts for retorting. Various mixts. of Pb, Zn and Ag were melted and crystd., by means of a kettle of 25 lb. capacity wound with resistance wire to permit close temp. control; bullion and crusts were sampled accurately with bullet molds. Curves were detd. showing the Ag and Zn content of the various molten mixt. at successive temp. as they cooled. The bullion which solidified, being the residu after the sepn. of the Zn crusts, was in each case a eutectic mixt. of Pb, Zn and Ag. The interpretation and use of the curves are explained, and different methods of zincking based on the curves are discussed. By liquefaction of the crusts and again cooling, an enriched crust is obtained which results in raising the Ag content of the retort bullion from 2000 to 16,000 oz. per ton. Formation of Ag_2Zn_3 does not play an essential part in desilverization and this compd. does not always exist in the crusts. It is not true that a fixed amt. of Zn (usually stated as 0.7%) must be added to the kettle before Pb will give up any of its Ag; this amt. varies with other factors and is lower the higher the Ag content of the bullion. A. BUTTS

Cyanide plant details. F. C. NINNIS. *Eng. Mining J.-Press* 120, 856-8(1925).—Describes a new device for adding CaO to cyanide solns., a crushing unit, an automatic sampler, an agitating tank, a pulp sampler, a furnace-charging hopper and a furnace gas-washing method. A. BUTTS

Complete heat balance of a standard blast furnace for the manufacture of Thomas iron, including that of the Cowpers and of the engines burning the furnace gases. MAURICE DERCLAYE. *Rev. métal.* 23, 1-7(1926).—The heat balance given in detail shows an efficiency of 46.5% from a metallurgical standpoint and of 8.9% from a power-generating standpoint, so that the overall efficiency is 55.4%. A. P.-C.

Evaluation of the characteristics of a blast furnace as a function of the quantity of slag. MAURICE DERCLAYE. *Rev. universelle mines* 8, 270-85(1925).—A mathematical paper, based on calcs. of the heat necessary for reducing the metallic oxides, fusing the crude metal and slag, decomp. the carbonates and evapg. and decomp. the H_2O . Equations are derived by which it may be detd. whether the furnace operation is normal, the influence of an increase in temp. of the blast, a change in the ash of the coke, an increased yield from the charge and a change in the coeff. of utilization of coke, either by a modification of the tuyères or by a change in the method of charging. Do free alkyl radicals occur in the Kolbe electrochemical hydrocarbon synthesis? H. ERLÉNMEYER. *Helvetica Chim. Acta* 8, 792-7(1925).—An attempt to decide between the free-radical theory of Crum Brown and Walker (*Ann.* 261, 107(1891)) and that based on Schall's assumption that peroxides are the intermediate products (*Z. Elektrochem.* 3, 83(1896)). Repetition of Kaufler and Herzog's expts. (C. A. 4, 212, 1049) on a quant. basis showed the yield of C_2H_6 on electrolysis of 40% KOAc soln. to remain as high (ca. 33%) after addn. of I_2 or Br_2 as in their absence, and that the amt. of MeI or MeBr formed did not exceed 0.6%, indicating its formation as a result of a side reaction. As Fichter (C. A. 18, 1438) has postulated the intermediate formation of AcO_2H (I) this might react in part according to $AcO_2H + HBr \rightarrow MeBr + CO_2 + H_2O$. I was prepd. in 80% yield according to d'Ans and Frey (C. A. 6, 2737) except that it was found better to add the H_2O_2 to a cooled H_2SO_4 - Ac_2O mixt. I reacted with NaBr in HOAc at 60°, giving a small amt. of MeBr, isolated as $PhNM_2Br$ (0.62 g. from 20 g. I). K. and H.'s work, therefore, does not support the theory of intermediate free radicals, as claimed. M. HEIDELBERGER

Electronic interpretation of the ethylenic linkage. HENRY GILMAN AND J. M. PETERSON. *J. Am. Chem. Soc.* 48, 423-9(1926).— $RMgX$ do not add in Et_2O soln. to substituted ethylenic compds. Under the conditions of the expts., there appear to be no active or polar forms of the ethylenic linkage, or the concn. of active forms is extremely small, or the active forms are not sufficiently active to add $RMgX$. $EtMgBr$ reacts 100% with di-*p*-tolylidysulfonylethylene but the nature of the reaction is as yet unknown. C. J. WEST

Nitrosate formation in olefins. F. W. KLINGSTEDT. *Ber.* 58B, 2363-70(1925); cf. Schaarschmidt and Hofmeier, C. A. 19, 2634.—Expts. on the action of N_2O_4 (partly with pure N_2O_4 , partly with the N oxides evolved from AmONO and HNO_3) on $Me_2C=CHMe$ (I) and $Me_2C=CH_2$ (II) showed that the yield of bisnitrosates (III and IV) depends greatly not only on the temp. and length of the reaction and on the qual. and quant. compn. of the reaction mixt. but also on the abs. amt. of the latter. With pure N_2O_4 in Et_2O or petroleum ether the yield of III is about 0.1 that obtained with AmONO

and HNO_3 at about -10° . II with free N_2O_4 in Et_2O at $3-10^\circ$ gave materially higher yields of IV. To obtain the max. yield of solid product some time must be allowed for the polymerization process and the temp. must not be allowed to rise much above 0° . On longer standing there set in, sooner or later, secondary reactions, depending on the temp., which may result finally in a complete disappearance of the bisnitrosates. This decompn., proceeding slowly with gas evolution at room temp., has its seat in the liquid, blue-green portion of the reaction product. The liquid undergoes, depending on the temp. of addn. and on that at which it is kept after the addn., a more or less rapid auto-decompn., often accompanied with a quite marked evolution of heat. Even during the addn. oxidation reactions may set in. In working up large amts. the temp. within the mixt. may easily rise too high, in spite of vigorous external cooling, with a consequent diminution in yield. Too great an excess of HNO_3 and the use of acid more dil. than 65% also result in a diminished yield. From 7.5–25 g. I with AmONO and H_2SO_4 was obtained 28–40% III, with N_2O_4 3.7–4.3%; from 3.8–10 g. II, 27.0–35.8 and 40%, resp., of IV. The quant estn. of the olefins on the basis of the yield of bisnitrosates is therefore very uncertain. Schmidt maintains (*Ber.* 35, 2336(1902)) that the blue-green liquid formed on the addn. of nitrous gases consists chiefly of the monomol. form of the dimeric nitrosate and gradually polymerizes to the latter in a cool dark place, but K. found that in all his expts. the polymerization was rapid (2–4 hrs., working with 4–25-g. portions of material), if the solid was removed at the end of this time, the liquid part showed no further tendency to polymerize and, unlike the solid nitrosate, which, when entirely pure, is stable, it was characterized by a marked lability. According to Wallach (*Ann.* 306, 281(1899)) the nitrolamines obtained from the bisnitrosates are monomol. compds. and it seemed possible that if the primary product of the addn. of N_2O_4 contained a nitrosate which for some reason did not polymerize or a dinitrosate which did not cryst. out it might, by the use of a suitable org. base, be isolated as the nitrolamine, especially as the well-washed but not recrystd. solid dinitrosates gave, with PhNH_2 , *c. g.*, const. (70–80%) yields of nitrolamine. The products obtained from the blue-green liquids with PhNH_2 or *p*- $\text{MeC}_6\text{H}_4\text{Me}$, however, were brown oils from which no solid nitrolamine could be isolated nor a solid chloride be pptd. with HCl in Et_2O ; owing to their instability, the oils could not be purified by distn.; that obtained from I gave, to be sure, in poor yield a N-contg. dark red chloroplatinate whose complete compn. has not been established but which is of a different type from the orange to yellow salts obtained in the same way from the solid nitrolamines. K. concludes that the liquid addn. products formed by the action of N_2O_4 consist chiefly of substances which in constitution or configuration are different from the monomol., easily polymerized nitrosates. Pure IV m. 116° (cor.) Hexenenitrolamine m. 86° . C. A. R.

The stereoisomers of chloriodoethylene. H. VAN DE WALLE AND A. HENNE. *Bull. sci. acad. roy. Belg.* [5], 11, 360–74(1925).—By absorbing $\text{CH}_2=\text{CHI}$ in a soln of ICl in 4 vols. aq. HCl crude $\text{CHCl}:\text{CHI}$ is obtained and is sepd. into its isomers by fractional distn. of its mixt. with an equal wt. of PrOH , the azeotropic mixt. of the *trans*-form with PrOH b_{760} $87.5-85^\circ$ and contg. 4% of alc., while the azeotropic mixt. of the *cis*-form b_{760} $93.6-4.0^\circ$ contg. 44.4% alc. After sepn. of the alc. from the azeotropic mixts. the yields from 2.475 kg. of crude $\text{CHCl}:\text{CHI}$ were 0.2 kg. of the *trans*- and 0.98 kg. of the *cis*-isomer. The const. of the *trans*- and *cis*-isomers arc, resp., b_{760} $113-4^\circ$, $116-7^\circ$. m. -41.0° , -36.4° ; d_4^{15} 2.1048, 2.2080; d_4^{20} 2.1355, 2.2399; n for various lines, n_D 1.56562, 1.57684, D 1.57146, 1.58288, H_B 1.58598, 1.59808, H_γ 1.59858, 1.61131; sp. inductive capacity (dielec. const.) 2.95, 2.72; relative rapidity of action with KOH 0.55, 1.00. If either isomer is exposed to sunlight for 1 hr. the same equil. mixt. is obtained, whose const. (n and d .) show it to contain 17.5% of the *trans*-isomer, the actual decompn. being slight although some reddish color is developed. W. B. P.

A new method for the separation of ethyl alcohol from acetaldehyde and acetone. G. GORR AND J. WAGNER. *Biochem. Z.* 161, 488–91(1925).—The mixt. is treated with HgCl_2 and NaOH (1 mol. aldehyde to 3–4 mols. HgO) and refluxed 4 or 5 hrs. The AcH ppts. as a Hg salt of unknown compn. The residue is then distd. and the alc. content of the distillate detd. by use of a pycnometer. Acetone ppts. much as does AcH , and the same method may be used for its removal. This sepn. is useful in a study of alc. fermentation. W. D. L.

Electropyrogenic decomposition of ethyl alcohol. F. G. MÜLLER. *Helvetica Chim. Acta* 8, 821–5(1925).—An arc was used at 30–35 v. and 25–30 amp. burning between a fixed Fe electrode and a movable C electrode insulated from the glass or Cu reaction vessel by asbestos packing. A 50-cm. Cu reflux condenser was used, provided with a U tube with arms 15–20 cm. long, through which 100 cc. alc. could be added every 40–5 min. in order to keep the arc under alc. (originally 300 cc.). In 5 hrs. *ca.* 1 l. alc.

was decompd., yielding *ca.* 1200 l. gas which gave *ca.* 48 cc. condensate at 12–15° (I) and 60 cc. at –40–80° (II). C was liberated, part of which may have come from the C electrode. 30% aq.-alc. was left in the flask, depositing very little tar on distg. off the alc. I yielded 4 cc. AcH and 44 cc. alc., while II gave 2.5 cc. acetylenes (III), 8 cc. AcH, and alc. The gases consisted of C₂H₂, 7–9.9%; C₂H₄, 6–9.6%; satd. hydrocarbons, 6.8–20.4%; CO, 20.4–23.8%; and H₂ 46.2–49.9%. PHH was absent. The isolation of HC:CC:CH in small amt. from III (cf. following abstr.) is new, and this is considered a possible intermediate in the formation of C₁₀H₈ and C₁₄H₁₀ in other pyrogenic decompns.

M. HEIDELBERGER

Diacetylene (butadiene). F. G. MÜLLER. *Helvetica Chim. Acta* **8**, 826–32(1925); cf. preceding abstr.—0.5–1.0 g. HC:CC:H (I) was isolated from each l. of alc. decompd. I could not be sepd. entirely from AcH by fractionation, but with cold Ag⁺-NH₃ soln. it gave the yellow explosive Ag salt, stable under H₂O. Decompd. with HCl this yielded I still contg. C₂H₂ and homologs. The final purification was accomplished at 10 mm. and low temps. in a somewhat modified Stock app. (*C. A.* **8**, 1248, 12, 547; **15**, 3256). The vapor pressure of I at –40° is 66.2 mm.; at 0°, 466.7 mm., and is calcd. to be 760 mm. at 13.6°. Values between –40° and 0° are given, also the difficult analyses and mol. wt. detn. Polymerization begins above 0°, the color becoming yellow within 5 min. in the light, longer in the dark with formation of a brown-black mass (II) in several days to 4 weeks. I m. –36–7°, and was once obtained as a blue, instead of colorless, liquid. It reacts violently with Br₂; the hexabromide, m. 181° (cor.) (cf. Noyes and Tucker, *J. Am. Chem. Soc.* **19**, 123(1897); Lespieau and Prévost, *C. A.* **19**, 1693, 2472, 2635), probably has the open-chain structure and a double bond, as it reacts with KMnO₄. I gives a brown-red, explosive Cu salt with Illosvay's reagent (*Ber.* **32**, 2698(1899)); with I₂ the Ag salt gives C₂H₂I₂, m. 93°, explodes 95°. II does not m. 350°, explodes at higher temps., is insol.

M. HEIDELBERGER

Some derivatives of ethyl selenomercaptan. E. H. SHAW, JR., and E. E. REID. *J. Am. Chem. Soc.* **48**, 520 8(1926).—EtSeH was prepd. by a modification of Siemens' method (*Ann.* **61**, 360(1847)), the av. yield being 40%. EtSeH condenses with ketones (HCl gas) giving about 97% of mercaptols: Me₂CO gives 2,2-bis[selenoethyl]propane, b₁ 81°, d₄⁰ 1.4577, d₂₅²⁵ 1.4329, the butane deriv., b_{3.5} 91.5°, d₄⁰ 1.4294, d₂₅²⁵ 1.4064; the pentane deriv., b₃ 104.5°, d₄⁰ 1.3825, d₂₅²⁵ 1.3608; oxidation of either of these gave a nearly quant. yield of EtSeO₂H. The HNO₃ compd., EtSeO₂H·HNO₃, m. 80° (cor.), gradually decompd. at 100°; the HCl compd., m. 107° (decompn.), when the heating is 14° per mm. With HBr there results, instead of the expected HBr compds., 89% of ethyl-selenium tribromide, darkens 50°, decompd. 73°. Oxidation of the mercaptols with 3% H₂O₂ yields a soln. of EtSeO₂H which can be concd. to a thick sirup without crystg. Free halogens break the bonds between the Se and the C in the mercaptols; SeCl₄ and SeBr₄ result, together with viscous evil-smelling oils. (ClCH₂CH₂)₂S and EtSeH in NaOH give 63% of bis-[β-ethylselenomercaptoethyl] sulfide, b₄ 171°, m. 15°, d₂₅²⁵ 1.4724. The sulfide decompd. on heating. The sulfone, m. 72.5°; yield, 84%. Anthraquinone 1-butylsulfone 5-ethyl selenide, deep red, does not m. at 300°. Other Na salts are reduced to the non-reactive hydrol form before the reaction takes place.

C. J. WEST

Esterification of aliphatic acids in glycerol. A. KAILAN and H. RAUPENSTRAUCH. *Monatsh.* **45**, 485–518(1925).—The rates of esterification of heptico acid in abs. glycerol, of iso- and n-valeric and hexoic acids in abs. and aq. glycerol, in presence of HCl, at 25°, have been measured. Contrary to esterification in mixts. rich in water, the unimol. reaction consts. are proportional to the total concn. of HCl. With valeric acid, a measurement was also made of the rate of esterification in presence of H₂SO₄ in aq. glycerol. Expressions are derived for the variation of the velocity consts. with the water content of the system with the valeric acids. The velocity consts. for the esterification of the above normal aliphatic acids have the same value, with the same catalyst, as that for butyric acid, while the const. for isovaleric acid is much smaller. The retarding influence of water is also the same as that with butyric acid, and similarly much less with glycerol than with EtOH. Thus, in presence of N/6 HCl, the above aliphatic acids are esterified, with EtOH, in mixts. contg. 0.03 mol. of water per l., about 4 times as rapidly as with glycerol, while when the water concn. is 4/3 mols. per l. the rates are about the same. The rate of esterification at 35° is 2.7 times that at 25°. The rate of esterification of H₂SO₄ with glycerol in presence of water is proportional to the 2/2 power of its concn. Valeric acid is esterified with glycerol about 1.7 times as fast in presence of HCl as in presence of H₂SO₄. Measurements of the rates of esterification of iso- and n-valeric, hexoic and heptico acids, in absence of catalyst, were made at 183.5°,

both with abs. and aq. glycerol, and showed that the rate of esterification under these conditions is proportional to the 3/2 power of the concn. of the acid present, indicating a catalysis by H ions. Water acts as an accelerator up to a concn. of 7 mols./l., thereafter exerting a retarding influence.

B. C. A.

Aliphatic nitro alcohols. ERICH SCHMIDT, ALFONS ASCHERL, AND LUDWIG MAYER. *Ber.* 58B, 2430-4 (1925); cf. C. A. 16, 2475.—In the present paper are reported the conditions under which hydroxylamino alcs. may be obtained in pure form by the catalytic reduction of the NO₂ alcs. 1-Nitro-2-pentanol (71% from PrCHO and MeNO₂ in cold H₂O with KOH), b₃ 87-8°, n_D²⁰ 1.4421, d₄²⁰ 1.0847. Me₂CHCH(OH)CH₂NO₂ (67.5% from iso-PrCHO), b₄ 83-4°. Me₂CHCH₂CH(OH)CH₂NO₂ (64.5% from iso-BuCHO), b₂ 90-1°, b₆ 99-100°, n_D²⁰ 1.4433, d₄²⁰ 1.0519. The catalyst was palladinized BaSO₄ (5% Pd). (McNHOH)₂ (CO₂H)₂ (9 g. from 6.1 g. MeNO₂, 6.3 g. crystd. (CO₂H)₂ and 1 g. catalyst in 77 cc. H₂O), m. 158° (decompn.). 1-Hydroxylamino-2-propanol oxalate (81% from MeCH(OH)CH₂NO₂), m. 111°. 1-Hydroxylamino-2-butanol oxalate (79%), m. 100-1° (decompn.). 4-Hydroxylamino-2-methyl-3-butanol oxalate (76%), m. 106-8° (decompn.). 1-Hydroxylamino-2-pentanol oxalate, (prepd. in 96% alc.; yield, 81%), m. 99° (decompn.). 5-Hydroxylamino-2-methyl-4-pentanol oxalate (prepd. in AcOH-EtOH; yield, 69%), decomp. 144-5°. 1-Hydroxylamino-2-octanol oxalate (prepd. in AcOH-EtOH-H₂O; yield, 69.5%), decomp. 142-3°.

C. A. R.

Preparation of neutral phosphites from the hydrogen esters. (MLLE.) M. JANCZAK. *Roczniki Chem.* 4, 180-1 (1924).—The action of dialkyl phosphites on their Na salts leads to trialkyl phosphites; the Na salts have, therefore, the same structure as the latter and contain trivalent P, e. g., (RO)₂P^{III} ONa, while the H esters themselves have the formula (RO)₂PV(O)H; the formation of the Na salts thus involves tautomeric change. The formation of neutral esters can also be brought about by the action of AcOH on the above Na salts; the change is accompanied by partial conversion of the neutral esters into alkylphosphonates, (RO)₂PV(O)R. The Na salts are immediately decomposed by water, but not by alc.

B. C. A.

Tautomerism of dialkyl phosphites. III. T. MILOBEDZKI. *Roczniki Chem.* 4, 183-4 (1924); —It has been suggested by Nylén (C. A. 18, 3167) that Na di-Et phosphite is a deriv. of quinquevalent P from its behavior towards ClCH₂-CO₂Et. This view is contradicted by the results obtained by Janczak (preceding abstr.), which point to the existence of tautomerisms between pseudo-acids of the type (RO)₂PV(O)H and true acids, (RO)₂P^{III}(OH), in the process of salt formation. The fact that Nylén could not oxidize the salt by means of I in aq. soln. is due to the fact that it is immediately decomposed by water. The corresponding Ag salt, which is stable, may be a deriv. of quinquevalent P as suggested by Stelling (C. A. 18, 1239).

B. C. A.

Boroacetic anhydride as a reagent. II. OTTO DIMROTH, R. RUCHTI, K. SAGS, TETTER, J. HETZER, H. BERNZOTT, C. BAMBERGER, O. REBMANN AND R. SCHWEIZER. *Ann.* 446, 97-122 (1925); cf. C. A. 16, 1766.—The boroacetic anhydride of Pictet and Geleznoff (*Ber.* 36, 2219 (1903)) is obtained only as a pyroboroacetate (I), B₂OAc₄, m. 150-2°; slowly heated at 150-60°, it splits off Ac₂O, giving metaboroacetate, BO₂Ac; crystn. from Ac₂O regenerates I. The use of this reagent in detg. the structure of certain classes of compds is illustrated. I and hystazarin give only the di-Ac deriv. Anthragallol and I in Ac₂O give the boroacetate of 2,3-diacetylanthragallol, orange, easily decompd. into H₂BO₃, AcOH and 2,3-diacetylanthragallol, m. 214°. 1-Aminoanthraquinone gives an orange soln. in Ac₂O, changed to red-violet by I, from which crystals the boroacetate, deep violet tablets heating *in vacuo* in a C₆H₄Me₂ bath for 38 hrs. gives the red-violet melaborate, C₁₄H₇O₂NHBO. Heating 0.5 hr. with Ac₂O gives the Ac deriv., m. 203°. The 2-NH₂ deriv. shows no color change with I but yields the Ac deriv. The 1,4-(NH₂)₂ deriv. gives a diboroacetate, deep violet prisms. The 1,5-(NH₂)₂ deriv. gives a brown-violet diboroacetate, brown, glistening prisms. The 1,8-(NH₂)₂ deriv. gives only the di-Ac deriv. 1,5-Dihydroxy-4,8-diaminoanthraquinone gives a violet-blue color in Ac₂O, with I a green-blue color, from which crystals. the diboroacetate, brown prisms; hydrolysis yields diacetylanthranthrafin, m. over 270°. 1-Hydroxyxanthone yields a deep yellow boroacetate, while the 2- and 4-HO derivs. are not colored by I. 1,8-Dihydroxyxanthone yields a mono-Ac boroacetate, citron-yellow prisms, slowly hydrolyzed by H₂O. 1-Hydroxy-4-aminophenanthraquinone gives a dark boroacetate, hydrolyzed to a N-Ac deriv. I and 2,3,4-trihydroxybenzophenone in Ac₂O give in the cold a labile ester, which upon standing or warming yields the 3,4-di-Ac deriv., m. 119°. 2-Aceto-1-naphthol boroacetate, honey-yellow, with green fluorescence. 1-Aceto-2-naphthol boroacetate, orange-yellow 3-Aceto deriv., orange. 2-Benzo-1-naphthol boroacetate, light orange glistening prisms. 2,4-Diaceto-1-naphthol boroacetate, dirty yellow. 2-Aceto-1,8-dihydroxynaphthalene-1-

boroacetate, brick-red. If the soln. stands, the color changes from red-brown to a deep greenish brown and on diln. with Ac_2O shows a very strong green fluorescence. Hydrolysis gives *8-acetoxy-2-aceto-1-hydroxynaphthalene*, pale green, m. 168–9°, which gives a *boroacetate*, glistening yellow leaflets. The *di-Ac deriv.*, m. 146°, likewise gives the same *boroacetate*. 8-Acetoxyquinoline, m. 55.5–6.5°; from 50% AcOH it crystals with 1 AcOH , m. 59–60°; from H_2O as a hydrate. $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ and **I** in Ac_2O give *salicyl boroacetate*, whose formula is not definitely established; on warming with Ac_2O complicated decompn. follows. AcOH gives borodisalicylic acid, which also results from $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ and **I** in Et_2O or C_6H_6 . *m*- and *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ give only the *Ac* derivs. of the acids.

C. J. WEST

The reaction of organomagnesium compounds on nitriles. P. BRUYLANTS. *Bull. sci. acad. roy. Belg.* [5], 11, 261–80 (1925).—Previous studies (cf. *C. A.* 18, 529, 815, 816; 19, 37, 288, 822) have shown that nitriles of the type $\text{R}_2\text{NCHR}'\text{CN}$ generally react with $\text{R}''\text{MgX}$ to substitute R'' for the CN group, although in some cases the product is $(\text{R}_2\text{NCHR}')_2$ by doubling up the original mol. with elimination of CN. The present work shows this also to be general for nitriles of the type $\text{R}_2\text{NCR}_2'\text{CN}$. $\text{Me}_2\text{NCMeEtCN}$ (**I**) with PhMgBr gives $\text{Me}_2\text{NCMeEtPh}$, b_{776} 234–5°, d_{20} 0.9275, n_D^{20} 1.5097; picrate, m. 178°. With PhCH_2MgBr **I** gives $\text{Me}_2\text{NCMeEtCH}_2\text{Ph}$, b_{771} 258°, d_{20} 0.9265, n_D^{20} 1.5152; chloroplatinate, m. 194°. With EtMgBr **I** gives $\text{Me}_2\text{NCMeEt}_2$, b_{769} 146°, d_{20} 0.7830, n_D^{20} 1.4306. α -Methyl- α -piperidobutyronitrile (**II**) with PhCH_2MgBr gives $\text{MeEt}(\text{C}_6\text{H}_{10}\text{N})\text{CCH}_2\text{Ph}$, b_{760} 310°, d_{20} 0.9614, n_D^{20} 1.5277; chloroplatinate, m. 192°. With PhMgBr **II** gives $\text{MeEt}(\text{C}_6\text{H}_{10}\text{N})\text{CPh}$, b_{760} 288–90°, d_{20} 0.9611, n_D^{20} 1.5253; chloroplatinate, m. approx. 205°. With EtMgBr **II** gives $\text{Me}(\text{C}_6\text{H}_{10}\text{N})\text{CEt}_2$, b_{768} 214°, d_{20} 0.8614, n_D^{20} 1.4637. By the reaction of $\text{CH}_2\text{:CHCHO}$ with KCN and $\text{Me}_2\text{NH}\cdot\text{HCl}$ is obtained 30% of $\text{Me}_2\text{NCH}_2\text{CH}_2\text{CH}(\text{NMe}_2)\text{CN}$ (**III**), b_{110} 90°, d_{20} 0.8876, n_D^{20} 1.4416. With PhMgBr **III** gives $\text{Me}_2\text{NCH}_2\text{CH}_2\text{CH}(\text{NMe}_2)\text{Ph}$, $b_{110.5}$ 128.5°, b_{768} 259°; HCl salt, m. 245°. The strong influence of the $\alpha\text{-NR}_2$ group in causing exchange of CN for the radical of the RMgX is very evident here, since $\gamma\text{-NR}_2$ substituted nitriles are ordinarily polymerized by RMgX . By reacting the HCl salt of piperidine with $\text{CH}_2\text{:CHCHO}$ and KCN is obtained 30% of $\text{CH}_2\text{:CHCH}(\text{NC}_5\text{H}_{10})\text{CN}$, b_{110} 94°, d_{20} 0.9813, n_D^{20} 1.4746, which with PhMgBr gives 40% of $\text{CH}_2\text{:CHCHPhNC}_5\text{H}_{10}$, b_{702} 271°, d_{20} 0.9704. n_D^{20} 1.5305; chloroplatinate, m. 176°. From MeCH:CHCHO with $\text{Me}_2\text{NH}\cdot\text{HCl}$ and KCN (g. mol. quantities) is obtained 17 g. of $\text{MeCH:CHCH}(\text{NMe}_2)\text{CN}$, $b_{110.5}$ 64–5°, d_{20} 0.8761, which with PhMgBr gives 60% of $\text{MeCH:CHCH}(\text{NMe}_2)\text{Ph}$, b_{768} 237°, d_{20} 0.9135.

W. B. PLUMMER

The reaction of organomagnesium compounds on nitriles. VELGHE. *Bull. sci. acad. roy. Belg.* [5], 11, 301–8 (1925).—Continuation of the preceding work (cf. preceding abstr.) with various α -aminoisobutyronitriles gives the same general result, viz., the CN group is exchanged for the radical of the RMgX . α -Piperidobutyronitrile (**I**) with EtMgBr gives $\text{Me}_2\text{EtCNC}_5\text{H}_{10}$, b. 188°, d_{20} 0.8608, n_D^{20} 1.4593. With MeMgBr **I** gives $\text{Me}_2\text{CNC}_5\text{H}_{10}$, b_{768} 166°, d_{20} 0.8465, n_D^{20} 1.4532; chloroplatinate, m. 235°. With PrMgBr **I** gives $\text{Me}_2\text{PrCNC}_5\text{H}_{10}$, b_{769} 205–7°, d_{20} 0.8517, n_D^{20} 1.4592. $\text{Me}_2\text{NCMe}_2\text{CN}$ (**II**) with MeMgBr gives doubling, with the formation of 67% of $\text{Me}_2\text{C}(\text{NMe}_2)\text{C}(\text{NMe}_2)\text{Me}_2$, b_{767} 149°. With EtMgBr **II** reacts mainly in the sense of the last reaction above to give 69% of diamine, but 15% of $\text{Me}_2\text{NCMe}_2\text{Et}$, b. 115°, also is formed by the normal reaction. With PrMgBr **II** forms a small amt. of the same diamine together with 20% of $\text{Me}_2\text{NCMe}_2\text{Pr}$, b. 138–9°, d_{20} 0.7950; chloroplatinate, m. 230°.

W. B. P.

Basis for the physiological activity of certain -onium compounds. IV. The sulfur analog of choline. R. R. RENSHAW, N. BACON AND J. H. ROBLER. *J. Am. Chem. Soc.* 48, 517–20 (1926); cf. *C. A.* 20, 364.— Me_2S and $\text{ICH}_2\text{CH}_2\text{OH}$ give *hydroxyethyl-dimethylsulfonium iodide*, hygroscopic needles, which soon decomp. on standing. Similarly Me_2S and BrCH_2OAc give *acetoxymethyl-dimethylsulfonium bromide*, m. 104° (cor.); in the presence of moisture or any foreign material, they decomp. on standing. Heated in EtOH it dissociates, giving Me_2S and HCHO . The pharmacol. examn. of the latter substance indicates that the -onium element is significant in detg. the stimulating nicotine effect.

C. J. WEST

The decomposition of diazo compounds under the influence of copper. J. S. P. BLUMBERGER. *Chem. Weekblad* 22, 599–604 (1925).—A review of the literature. Only Cu^+ halides form intermediate compds. with the diazo compds. Cu and all other Cu salts act merely by surface catalysis. In discussing the Sandmeyer and related reactions and the nature of the cupro-diazo compds., it is pointed out that the theory of induced alter-

nate polarity ought to prove valuable for the understanding of the influence of substituents on these reactions.

MARY JACOBSEN

Identification of monosubstituted acetylenes. Derivatives of diethynyl mercury. J. R. JOHNSON AND W. L. McEWEN. *J. Am. Chem. Soc.* **48**, 469-76 (1926).—Simple Hg salts of the formula $(RC \equiv C)_2Hg$ are formed by treating monosubstituted acetylenes with an alk. soln. of HgI_2 or $Hg(CN)_2$. *Dipropynyl Hg*, m. 203-4° (16% yield on the 1,2- $C_3H_5Br_2$ used). *Dibutynyl Hg*, m. 162-3° (34% yield on the 1,2- $C_4H_9Br_2$ used). *Di-[3,3-dimethylbutynyl] Hg*, m. 91-2° (94%). *Diheptynyl Hg*, m. 61° (80%). *[2-Bromo-1-decene, b₂₂ 115-6°, b₃ 76-7°, d₂₀⁰ 1.1044, d₂₀²⁰ 1.0844, n_D²⁰ 1.46015, 1.46290, 1.47011 for C, D and F, MR_D 55.630 (calcd., 55.628), in 60% yield from $C_7H_{15}MgBr$ and $BrCH_2-CBr:CH_2$; $NaNH_2$ gives 68% of 1-decine; *didecynyl Hg*, m. 83-4° (70%). *Diphenylpropynyl Hg*, m. 106.5-7.5°. $PhC \equiv CMe$ did not give a Hg salt. *4-Phenyl-2-bromo-1-butene*, b₆ 77-8°, b₂₁ 117-8°, d₂₀⁰ 1.3102, d₂₀²⁰ 1.2924, d₄²⁰ 1.2901, n_D²⁰ 1.5450, MR_D 51.73 (calcd. 52.03); 44% yield; $NaNH_2$ gives 63% 4-phenyl-1-butene. *Diphenylbutynyl Hg*, m. 83.5-4.5° (95% yield). *Di-p-tolyethynyl Hg*, m. 199-202° (75%), di-p-anisylethynyl Hg, m. 207-9° (95%). *Dicyclohexylpropynyl Hg*, m. 104° (78%). *Diphenoxypropynyl Hg*, m. 120.5-1° (84%).*

C. J. WEST

The action of halogens on acrolein in dilute aqueous solution and the preparation and properties of certain trihalogenated propionic acids. A. BERLANDE. *Bull. soc. chim.* **37**, 1385-94 (1925).— α, α, β -Trihalogenated propionic aldehydes are readily prepd in good yield by the action of halogens on α -monohalogenated acrolein in an inert solvent. Cautious oxidation with HNO_3 gives the corresponding acid. B. sets out to improve the methods of prep. α -monobromo- and α -monochloroacrolein and to prep. α -moniodoacrolein. He does so by acting on acrolein with halogens in dil. aq. soln. The mechanism of the reaction is discussed and shown to be as follows: $CH_2:CHCHO + X_2 \rightleftharpoons CH_2XCHXCHO \rightleftharpoons HX + CH_2:CXCHO$. Details of the prep. and properties of $CH_2:ClCHO$ and of the aldehydes, acids and *Et* esters corresponding to the following acids are given: $CH_2BrCBr_2CO_2H$, $CH_2ClCIClBrCO_2H$, $CH_2ClCCl_2CO_2H$ and $CH_2BrCClBrCO_2H$.

R. E. GIBSON

Platinum oxide as a catalyst in the reduction of organic compounds. XII. Selective reduction of citral by means of platinum oxide-platinum black and a promoter. ROGER ADAMS AND B. S. GARVEY. *J. Am. Chem. Soc.* **48**, 477-82 (1926); cf. *C. A.* **20**, 376.—Citral may be reduced quant. to geraniol by means of PtO - Pt black and H in the presence of small amts. of promoters such as $FeSO_4$ or $Zn(OAc)_2$. When 2 mol equivs of H instead of 1 are used, pure citronellol results, while with 3 equivs. tetrahydrogeraniol is obtained. Geraniol is reduced to citronellol and then to tetrahydrogeraniol. Promoters for the citral reduction act as poisons in this reduction.

C. J. WEST

Polarimetric study of mixtures of optically active organic acids with aldehydes and ketones. MARIO PASSERINI. *Gazz. chim. ital.* **55**, 726-9 (1925).—In some previous papers (*C. A.* **16**, 555, 556; **18**, 245) P. suggested that in mixts. of org. acids with ketones or aldehydes addn. products, $RR'C(OH)OCOR''$, are formed. This having been confirmed for aldehydes (and ketones) and organic acids (*C. A.* **19**, 822), P. has now investigated optically active acids. The data on the rotation of optically active org. acids mixed with various ketones and aldehydes conform with the previous results and it is suggested that the formation of the same addn. product accounts for the large changes observed in the optical rotation for the optically active acids used.

E. J. W.

Separation of the liquid linolic acids by fractional solution of their zinc salts in alcohol. GG. AGDE. *J. prakt. Chem.* **112**, 37-56 (1926).—A careful re-exam. of the work of Erdmann (*C. A.* **6**, 862) shows that his results cannot be reproduced and that it is impossible to sep. the liquid linolic acids by the fractionation of their Zn salts in $EtOH$.

C. J. WEST

X-ray crystal analysis as an auxiliary in organic chemical research. R. ROBINSON. *Nature* **116**, 45 (1925).—A brief account of the successful application, by Shearer, of X-ray analysis to the detn. of the length of C chains and the position of a C:O group. Similar investigations indicate that the acetylenic linking of stearolic acid is hydrated in each of the theoretically possible directions, i. e., $Me[CH_2]_7CO[CH_2]_nCO_2H$ and $Me[CH_2]_nCO[CH_2]_7CO_2H$, when the substance is treated successively with H_2SO_4 and water.

B. C. A.

The catalytic decomposition of amides. ALPHONSE MAILHE. *Bull. soc. chim.* **37**, 1394-7 (1925).—When the vapors of acid amides are passed over a freshly reduced Ni catalyst heated to ca. 400°, CO is split off and an amine contg. one C atom less than the amine is unaltered and appears in the end products, but with the alkyl amides, of which $Me_2CHCH_2CONH_2$, $EtCONH_2$ and $AcNH_2$ are described in full, the amine is

further decompd. to a nitrile, $\text{AcNH}_2 \rightarrow \text{MeNH}_2 \rightarrow \text{HCN}$. This is important as a ready method of degradation in an homologous series. R. E. GIBSON

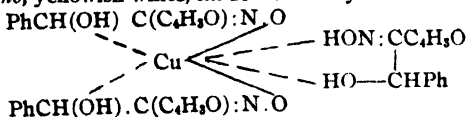

The imine residue. K. F. SCHMIDT. *Ber.* 58B, 2413-5(1925).—Reply to Oliveri-Mandalà (*C. A.* 19, 2791). C. A. R.

Butyl esters of the simpler amino acids. W. T. J. MORGAN. *J. Chem. Soc.* 1926, 79-84.—These esters were prepd. as a possible means of sepg. the hydrolysis products of proteins. They were first isolated as the HCl salt and liberated by $\text{Ba}(\text{OH})_2$ in Et_2O followed by a little 70% KOH . *Bu glycine*, b_{18} 81-1.5°, d_{18} 0.9703; in a sealed tube it changed in 24 hrs. to a cryst. solid, charring at 240° (triglycylglycine *Bu ester*?); *HCl salt*, m. 69-71°; *picrate*, pale yellow, m. 113°; *benzoquinone deriv.*, scarlet, m. 179-80°. *Bu carbamidoacetate*, m. 119°. *Isobutyl glycine*, b_{18} 79.5-80.5°, d_{17} 0.9618, d_{20} 0.9609; *HCl salt*, m. 84-8°, very hygroscopic and quickly liquefies in the air; *picrate*, m. 82-7°, *benzoquinone deriv.*, scarlet, m. 171-2°. *Bu dl-alanine*, b_{18} 81.5-2°, d_{19} 0.9342; *HCl salt*, m. 58-61°, rapidly deliquesces in moist air; *picrate*, m. 124°. *Isobutyl dl-alanine*, b_{19} 77-8°, d_{18} 0.9330; *HCl salt*, m. 60-3°, changes to a sirup on exposure to the air for a few min.; *picrate*, m. 132-3°. *Bu dl-valine*, b_{17} 98-8.5°, d_{14} 0.9266; *HCl salt*, m. 59-60°, *picrate*, yellow, m. 91-2°. *Bu dl-leucine*, b_{18} 113.5°, $d_{18.5}$ 0.8733; *HCl salt*, m. 110-1°, very hygroscopic; *picrate*, yellow, m. 139°. *Isobutyl dl-leucine*, b_{19} 110°, $d_{18.4}$ 0.9066; *HCl salt*, m. 97-9°; *picrate*, m. 135-6°. C. J. WEST

Relations between atomic grouping and specific affinity. The copper-affinity effectiveness of the atomic grouping $>\text{C}(\text{OH})\cdot\text{C}(\text{:N}\cdot\text{OH})\cdot$. F. FEIGL, G. SICHER and O. SINGER. *Ber.* 58B, 2294-303(1925); cf. *C. A.* 18, 30.— $\text{PhCH}(\text{OH})\text{C}(\text{:NOH})\text{Ph}$ (I), as shown in the earlier paper, may be used for the quant. detn. of Cu ; as in the ppt. formed with Cu^{++} in NH_4OH the Cu atom is unable to add NH_3 as a neutral component with the formation of ammine salts the ppt. was formulated as an inner complex salt,

$\text{Ph} \overline{\text{CH} \text{ O} \cdot \text{Cu} \cdot \text{O} \cdot \text{N} \cdot \text{C}} \cdot \text{Ph}$, in which the affinity field of the C double bonds of each

Ph group occupies a coordination position on the Cu atom and therefore sats. a secondary valence just as an added NH_3 mol. would. This assumption had to be proved by a study of the homologs of I and it was found that all acyloin oximes, $\text{RCH}(\text{OH})\text{C}(\text{:NOH})\text{R}'$, yield green, H_2O -insol. Cu salts of the same compn., which are decompd. by acids. Varying R and R' produces no change in this respect; their influence is shown only in the behavior towards NH_3 ; it is the grouping $=\text{C}(\text{OH})\text{C}(\text{:NOH})\cdot$, therefore, to which a Cu affinity must be ascribed. Insol. in NH_4OH or inability to add NH_3 results when R and R' are able to sat. Cu coordinatively; aromatic radicals are always able to do this, and there is no difference between sym. and asym. acyloin oximes. Substituents in the Ph group have no influence. In the aliphatic acyloin oximes only those radicals in which the C chain has more than 3 members have such a power to sat. Cu coordinatively. Cu salts of the oximes of the following compds. have been prepd., those marked s being sol. in NH_3 : fructose, s; acetol, s; acetoin, s; propioin, s; butyroin, s; valeroïn; capronin; enanthoin; diphenylacetoin; benzoin; furoin; anisoïn; cuminoïn; piperonyloïn; phenyloxyethenylamide, difficultly sol.; benzofuroin; benzanisoin; cumin-anisoin; p-dimethylaminobenzoin; p-chloro-p'-dimethylaminobenzoin; phenylbenzoin, s. benzylbenzoin, s. Valeroïn, from BuCO_2Et by the method of Bouveault and Locquin (*Bull. soc. chim.* [3], 35, 629(1906)), b_{12} 100-2°. Enanthoin, from Et enanthate in abs. Et_2O with Na on the H_2O bath, b_{10} 165-8°. Diphenylacetoin, from $\text{PhCH}_2\text{CO}_2\text{Et}$, b_{12} 160°. Benzoin oxime with $\text{Ni}(\text{OAc})_2$ also forms a flesh-colored amorphous compd. $[\text{PhCH}(\text{OH})\text{CPh}\cdot\text{NO}]_2\text{Ni}$, whose sepn. is hindered in tartaric acid and it is therefore probably a normal salt. Cuminoin oxime, yellowish white, m. 137°. Benzofuroin oxime, m. 158°; this also gives a brown Cu salt, $\text{PhCH}(\text{OH})\text{C}(\text{C}_6\text{H}_5\text{O})\cdot\text{N}\cdot\text{O}$

prepd. by treating the normal salt in H_2O suspension with concd. H_2SO_4 ; with NH_3 it gives the normal salt. C. A. R.

Keto-enol isomerism of ethylenebisacetylacetone. G. T. MORGAN and C. J. A. TAYLOR. *J. Chem. Soc.* 1926, 43-9.— $\text{C}_2\text{H}_5\text{Br}_2$ and Ac_2CHNa give ethylenebisacetylacetone, sepd. by fractional distn. into the keto form (I), b_{20} 97-9°, sol. in dil. NaOH to a yellow soln., and gives a Na salt with metallic Na in Et_2O ; the EtOH slowly develops a color with FeCl_3 ; a possible dehydration product, $\text{C}_{10}\text{H}_{10}\text{O}_4$, which does not give a color with FeCl_3 ; the mono-enol form (II), m. 99°, which gives an instantaneous deep violet

color with FeCl_3 and a Cu salt with $\text{NH}_4\text{OH}\cdot\text{Cu}(\text{OAc})_2$; after several months the m. p. was $146\text{--}52^\circ$; and the *dienol form* (III), m. $140\text{--}3^\circ$. Titration with Br in EtOH indicates that I contains about 0.8% of II, that II is pure and that III contains about 25% of the dienol and 75% of the monoenol. I yields an α -tetraoxime, m. 165° ; II, the β -tetraoxime, m. $220\text{--}2^\circ$. I and TeCl_4 give a small yield of β -chloroethylacetylacetone, m. 79° . II gives a yellow soln. in NaOH and yields no ppt. on addn. of H_2SO_4 , but Et_2O exts. I. II is partly changed into III under the influence of $\text{NH}_4\text{OH}\cdot\text{Cu}(\text{OAc})_2$. C. J. WEST

Influence of carbon rings on the velocity of reactions involving their side chains. I. Hydrolysis of cyclic and open-chain malonic esters. RICHARD GANE AND C. K. INGOLD. *J. Chem. Soc.* 1926, 10-7.—The results of the hydrolysis of $\text{CH}_3(\text{CO}_2\text{Et})_2$, $\text{CHMe}(\text{CO}_2\text{Et})_2$, $\text{CMe}_2(\text{CO}_2\text{Et})_2$, $\text{CHEt}(\text{CO}_2\text{Et})_2$, $\text{CEt}_2(\text{CO}_2\text{Et})_2$, $\text{CHPr}(\text{CO}_2\text{Et})_2$, iso $\text{PrCH}(\text{CO}_2\text{Et})_2$, Et cyclopropane-, -butane-, and -hexane-1,1-dicarboxylate by NaOH are reported and discussed. The points connecting the log of the initial velocities and the calcd. angles between the valencies carrying the CO_2H groups lie on a smooth curve both for the cyclic esters and the *gem*-di-Me ester. The curve indicates a value of 105.3° for the angle appropriate to the *gem*-di-Et ester. The curves of the tautomeric malonic esters show that the various alkyl groups exert an influence appropriate to their relative size, although it is difficult to express this effect quantitatively. C. J. WEST

Action of ammonia on the esters of citraconic, mesaconic and itaconic acids. K. STOSIUS AND E. PHILIPPI. *Monatsh.* 45, 457-70 (1925).—The action of anhyd. liquid NH_3 on Et citraconate at the ordinary temp. affords first the di-Et ester of homoaspartic acid, b₁₂ $118\text{--}9^\circ$ (cf. Philippi and Spenner, *C. A.* 9, 1302; the b. p. there recorded should read $125^\circ/18\text{ mm.}$), together with a trace of a substance, m. 185° . Continued action yields the diamide of homoaspartic acid, m. 175° (oxalate, m. 237°), which is hydrolyzed by boiling with water to the monoamide (homoasparagine), $\text{HO}_2\text{CCMe}(\text{NH}_2)\text{CH}_2\text{CO}_2\text{NH}_2$, m. 242° (cf. Piutti, *Ber.* 31, 2039-53 (1898)) which was also obtained together with α -mesaconamic acid (cf. Anschütz, *C. A.* 1, 2080), by the action of NH_3 on α -Et mesaconate, $\text{HO}_2\text{CCMe}\cdot\text{CHCO}_2\text{Et}$. Citraconic diamide was not among the products, but the action of NH_3 on Me citraconate yielded homoaspartimide, m. 185° , together with the above diamide. Homoaspartic acid, prepd. from homoasparagine (cf. Piutti, *loc. cit.*), crystallizes anhyd. from water and does not lose wt. at 180° , above which temp. it sublimes. The action of liquid NH_3 on Et mesaconate afforded mesacondiamide, while alc. NH_3 at 100° yielded Et homoaspartate and the above homoaspartimide. Et itaconate yielded similarly with liquid NH_3 2-ketopyrrolidine-4-carbamide, $\text{CH}_2\cdot\text{NH}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CHCONH}_2$, m. 217° , hot alc. NH_3 yielding again homoaspartimide. B. C. A.

Steric series. VII. The configuration of aspartic acid. KARL FREUDENBERG AND ALFONS NOË. *Ber.* 58B, 2399-408 (1925), cf. *C. A.* 20, 377.—It has been shown that sarcosolactic acid and natural alanine have the same configuration, and as natural malic (I) and natural aspartic (II) acids correspond, sterically, to the above 2 compds. they must also have the same configuration. A direct comparison of I and II has been made, both to confirm the above conclusion and to develop the technic, which is necessary in order that the α -haloaliphatic acids may also be included in the investigation. For the comparison were used analogous derivs. of the di-Et esters of the 2 acids: those of I are all liquid, while of the derivs. of II only the HCHO compd. is liquid, the others were used in the superfused state. Below are given, resp.: solvent (if any was used) and concn. in parentheses, temp., and $[\text{M}]_{578}^{25}$. *Di-Et L-malates*: Cinnamoyl (III), 20° , 6.7; 100° , -13.4. Benzoyl (IV), 20° , -12.4; 100° , -27.7. Formyl (V), 17° , -56.0; 100° , -58.1. *Hydrocinnamoyl* (VI), 20° , -55.8; 100° , -68.3. Acetyl (VII), 20° , -53.3; 100° , -67.5. (*Acetyl dimethylalanilide* (XII), (alc. 20.6), 20° , 62.7. *Dianilide* (XIII), (alc., 4.3), 20° , 166.6.) *Di-Et L-aspartates*: Cinnamoyl (XIV), 20° (superfused), 25.4; 100° , 19.7; (HCO_2H , 17.9), 22° , 63.5; (HCO_2H , 27.3), 18° , 79.4; (HCO_2H , 45.2), 18° , 94.8. Benzoyl, 100° , 11.8; (alc., 3.9), 14° , -67.6. ($\text{C}_6\text{H}_5\text{N}$, 3.0), 20° , -74.3; ($\text{C}_6\text{H}_5\text{N}$, 17.2), 20° , -73.3; ($\text{C}_6\text{H}_5\text{N}$, 30.3), 20° , -69.7. ((CHCl_2), 4.8), 20° , 142.9. Formyl (XV), 20° , -0.3; 100° , -12.9. *Hydrocinnamoyl* (XVI), 20° (superfused), -17.8; 100° , -9.1. Acetyl (XVII), 19° (superfused), -21.0. 100° , -9.1. (*Acetyl di-Me ester* (XVIII), 20° (superfused), -30.7; 100° , -25.0.) Heptoyl (XIX), 20° (superfused), -46.0; 100° , -19.9. *Ethanesulfonyl* (XX), 20° (superfused), -28.7; 100° , -31.2; ($\text{C}_6\text{H}_5\text{N}$, 8.12), 17° , -59.1; ($\text{C}_6\text{H}_5\text{N}$, 44.0), 17° , -62.9; ($\text{C}_6\text{H}_5\text{N}$, 74.4), 17° , -57.3; (HCO_2H , 27.7), 18° , -49.1; (HCO_2H , 47.9), 18° , -48.3; (HCO_2H , 76.5), 18° , -39.7. *p-Toluenesulfonyl* (XXI), 20° (superfused), 37.5;

100°, —36.0; (C_6H_5N , 10.9), 22°, —59.3; (C_6H_5N , 25.6), 22°, —60.7; (C_6H_5N , 36.3), 18°, —61.7; (C_6H_5N , 46.8), 22°, —58.5; (HCO_2H , 25.9), 18°, 9.6; (HCO_2H , 50.6), 18°, 14.5; (HCO_2H , 57.9), 18°, 17.8; (HCO_2H , 65.8), 18°, 19.3; ($(CHCl_2)_2$, 9.8), 18°, 109.2; ($(CHCl_2)_2$, 24.2), 18°, 96.6; ($(CHCl_2)_2$, 44.4), 18°, 85.61. $[\alpha]_D^{20}$ for λ 637, 578, 546 and 436 also is given. At 20° the agreement between I and II is poor but at 100° it is excellent, the only (insignificant) discrepancy being in the case of XVI. The Bz and $PhCH_2-CH_2CO$ derivs. have the highest d -rotation, the aliphatic derivs. occupy a middle position and the sulfonyl derivs. have the highest l -rotation. With increase in temp. in the derivs. of I (except the sulfonyl compds) the rotation is shifted towards the left, while in the derivs. of II the influence of temp. is entirely irregular and often extraordinarily great; evidently in the superfused state there exist associations which influence the form of the mols. and change the rotation; the true values for solids are more likely to be obtained at the higher temps. at which the liquid phase is stable. For the same reason, extrapolation of the values for solvent-free substances from values obtained in solvents is unreliable unless the concn. of the soln. is very high. The rule that Et esters of the d -series rotate far more to the right than the Me esters must for the present be limited to the α -HO acids and their derivs. In the action of HNO_2 on asparagine or aspartic acid there is no Walden inversion. III, light yellow, b_p 195°. IV, b_0 5.152°. V, b_2 120–1°. VI, b_3 185–6°. VII, b_{10} 139°. VIII, b_2 140°. IX, $b_{0.5}$ 154–5°. X, b_1 167–8°. $MeSO_2Cl$, b_{13} 60–4°. XI, b_1 197–8°, is not stable on standing; this and the di-Me ester give with alc. NH_3 , even at —50°, only formamide and $MeC_6H_4-SO_2NH_2$. Benzoyl- l -malic acid, m. 162°, $[\alpha]_{578}^{14}$ —1.2° (± 0.5) in Me_2CO . Acetyl- l -methyl dichloride, b_{14} 118°. XII, m. 116°. XIII, m. 177°. XIV, m. 72°, shows no detectable rotation in C_6H_5N in concns. up to 54%. XV, b_1 145–6°. XVI, b_2 203°, m. 34°. XVII, b_{20} 183°, m. 31°. XVIII, $b_{1.5}$ 154–5°, m. 63°. XIX, m. 29°. XX, m. 50°. XXI, m. 79°; free acid, crystals with H_2O , m. (anhyd.) 139–40°, has a weak d -rotation; dichloride, m. 96–7°. Addendum.—The work of Sonn and Rosinsky (*C. A.* 20, 360) confirms that of Freudenberg and Brauns upon which Kuhn and Ebel (*C. A.* 20, 742) throw some doubt.

Guanidine. G. PELLIZZARI *Mem. accad. naz. Lincei* (v), 14, 707–76 (1924).—A summary of P's investigations on guanidine, published since 1891 in 34 papers.

B. C. A.

Synthesis of galegine. ERNST SPATH AND WOLFGANG SPITZY. *Ber.* 58B, 2273–9 (1925).—Barger and White suggest (*C. A.* 18, 968) that in addn. to the structure $Me_2C:CHCH_2N:C(NH_2)_2$ (I) proposed by S. and Prokopp (*C. A.* 18, 2499) for galegine (II), it might have the structure $MeC:(CH_2)CH_2CH_2N:C(NH_2)_2$. Since $Me_2C:CHCH_2N_2H_2$ (III), which is obtained by the cleavage of II, gives II quite smoothly with $NCNNa_2$, it became incumbent to synthesize III in order to complete the artificial prepn. of II. This was finally effected after a no. of unsuccessful attempts. Dimethyl- β -iodoethyl-carbinol (27 g. from 54.4 g. $ICH_2CH_2CO_2Et$ with $MeMgI$), b_{12} 81–3°; attempts to split off H_2O from this compd. with $ZnCl_2$, ZnI_2 or P_2O_5 , or to replace the HO group by I with P and I and then split off HI led to no practical results; either there was resinification or sepn. of large amts. of free I. Direct distn. of the carbinol under atm. pressure gave I, III and a brown oil yielding a fraction, b_{10} 40–55°, which consisted in part of the expected β -isoamylenyl iodide, for with satd. alc. NH_3 at 100° it yielded a product giving the picrate, m. 138–9°, of III. Bromination of iso-Am NH_2 and subsequent splitting off of HBr, the action of $MeMgI$ on $H_2NCH_2CH_2CO_2Et$ or $HOCH_2CH_2CO_2Et$ and the Hoffmann degradation of $Me_2C:CHCH_2CONH_2$ likewise did not yield satisfactory results. Finally, $ClCH_2CH_2CO_2Me$, b_{10} 40–2°, obtained in 80.6 g. yield from 94 g. of the acid in MeOH satd. with HCl, was treated with 2.5 mols. $MeMgBr$ (from 190 g. MeBr), yielding 60 g. dimethyl- β -chloroethylcarbinol, b_{14} 62–3°, 19 g. of which (in 3 portions), heated in sealed tubes with $C_6H_5(CO)_2NK$ in xylene at 169° and finally at 218°, yielded 4.77 g. β -isoamylenylphthalimide, m. 100°; 3 g. of this, distd. with aq. $Ba(OH)_2$, the distillate then being neutralized with HCl, gave 1.65 g. III. HCl, identified with the product obtained from natural II through the picrate, m. 139–40°, m -nitrobenzoyl deriv., $C_{12}H_{14}O_3N_2$, m. 100°, and the chloroplatinate, m. 191–2° (decompn.) in an evacuated tube. The synthetic III. HCl (0.6 g.) with $NCNNa_2$ yielded 0.6 g. II picrate, m. 180–1°, further identified as the sulfate, m. 225–6° (in an evacuated tube), the 2,4,6-trinitro- m -cresolate, yellow, m. 160–1.5°, and the di- m -nitrobenzoyl deriv., m. 163–4°.

C. A. R.

New (observations) in sugar chemistry. VI. H. KILIANI. *Ber.* 58B, 2344–62 (1925); cf. *C. A.* 18, 665.—I. The lactone Na salt, $C_6H_7O_7Na$, of d -saccharic acid dissolves in 28 parts H_2O but the proposal to use it for the prepn. of d -saccharic acid

proved to be impracticable, for while the salt crystals so well when pure, its separation is hindered extraordinarily by the presence of a certain amount of other organic substances, a condition which is unavoidable in the oxidation of *d*-glucose or starch with HNO_3 . If into the pure lactone in 4 parts cold H_2O is stirred the necessary amount of solid crystalline NaOAc to form the Na salt the latter quickly begins to separate on vigorous stirring (even more readily after seeding), but if the same lactone is dissolved in 1 mol. cold *N* NaOH , the solution, in spite of its relatively greater concentration, cannot be made to yield crystals, even on seeding, and addition of several volumes of 95% alcoholic precipitates a sirup which, after again seeding, solidifies only very slowly in the course of several days, to a crystalline cake of the salt. The hoped-for transformation of the salt into glucuronic acid also ended in disappointment; the salt is not attacked at all in H_2O solution (1:30) by Al-Hg nor in 1:50 solution by Na-Hg when CO_2 is constantly passed in to combine with the Na; the yield of glucuronic acid on reduction in H_2SO_4 (Fischer and Piloty, *Ber.* 24, 521 (1891)) can be increased to 30%, starting from the free lactone, by turbinizing instead of "continuous stirring," and by adding dil. H_2SO_4 continuously at a measured rate from a dropping funnel instead of adding it "frequently." II. *Preparation of d-saccharic acid.* To eliminate the difficulties previously pointed out, all the factors have been studied individually and it has been found that (1) as raw materials must be used starch and 20% HCl (1 g. starch to 3.4 cc. acid), the mixture being allowed to stand 12 hours before the heating which (2) must be at 75° if 50 g. starch at most is oxidized in 1 flask and at first at $50-5^\circ$ if 50-250 g. starch is oxidized in 1 portion; (3) in any case, the mixture must be heated some hours at 100° at the end; (4) the $(\text{CO}_2\text{H})_2$ must be removed with CaCO_3 ; (5) the acid solution must be wholly neutralized with 1:2 KOH and, after evaporation at 50° , treated with AcOH (80 cc. for 250 g. starch), the acid K salt (yield, 23-5%) converted into the neutral salt and then, with 1:1 CaCl_2 into the Ca salt, which with $(\text{CO}_2\text{H})_2$ yields the free saccharic acid whose solution, concentrated to a sirup, readily solidifies to a cake of the monolactone, m. 130° ; the condensation of 0.5641 g. of the lactone in 10 cc. H_2O at $20.7-0.8^\circ$ changes only from 0.005357 to 0.005284 in 65 min. so that its conversion into the dibasic acid is slow. III. *Preparation of l-arabonic acid.* The method of Neuberg and Hirschberg (*C. A.* 5, 313) can be much simplified; 1 kg. cherry gum is heated 10 hours at 100° with 3 l. of 2% HCl , then 8 hours in a dish with occasional renewal of the evaporated H_2O , filtered, treated with 75 cc. Br , neutralized after 24 hours with freshly slaked lime, evaporated until a pellicle forms and allowed to stand several weeks; the crude salt can be recrystallized with the greatest ease from hot H_2O . The brucine salt contains $4\text{H}_2\text{O}$. IV. *Preparation of l-mannonic acid and l-gluconic acid.* The earlier method (*C. A.* 16, 2120) has been improved; after standing 5-6 days (the first 3 in a bath of cold H_2O) the *l*-arabinose- HCN mixture is stirred into 1.2 times the calculated amount of $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ in 4 parts H_2O on the H_2O bath, evaporated to a thick sirup and stirred until no more NH_3 is evolved, diluted with hot H_2O , treated with 0.8 times the calculated amount of H_2SO_4 (1 part concentrated acid to 4 parts H_2O), completely freed from the rest of the Ba with more dil. H_2SO_4 , evaporated to a sirup and worked up as previously described. The crude brucine *l*-gluconate is recrystallized from 0.5 part hot H_2O . The purified salt (m. 155°) is not, as previously supposed, homogeneous but contains a not inconsiderable amount of *l*-mannonate; the 2 acids can be separated by taking advantage of the fact that, contrary to the statement of Fischer, Ba *l*-gluconate (stout tables with $3\text{H}_2\text{O}$) crystals well and, therefore, *l*-gluconic lactone can readily be obtained in crystalline form. Pure brucine *l*-gluconate, m. $167-8^\circ$. V. *Salts of mucic acid.* Khotinsky and Epifanova (*C. A.* 19, 2640) obtained the anhydrous Na_2 salt from mucic acid and the calculated amount of *N* NaOH only because they boiled the mixture; 5 g. acid dissolved at first in the calculated amount of *N* NaOH but soon formed crusts and, on stirring, a crystalline powder of the Na_2 salt which, filtered after 1.5 hours, weighed 3.8 g.; this, heated 0.5 hr. at 100° with 25 cc. H_2O , at first almost wholly dissolved and then formed crusts and a finely pulverulent precipitate of the anhydrous salt (0.68 g.), while the mother liquor, concentrated to $\frac{1}{3}$ its volume and allowed to stand 12 hours, yielded a crust and a massive deposit of the hydrated salt (4.5 or possibly $5\text{H}_2\text{O}$). The Ca salt, precipitated from 1:40 and 1:60 solutions of the K salt by CaCl_2 in amorphous form, changes rapidly into characteristic stout granules; in a 1:80 solution there is at first only a slight turbidity but a granular crust is gradually formed; in concentrated solution (1:30) the change of the amorphous precipitate is much slower, being still very incomplete after 5 days. VI. Höning and Tempus (*C. A.* 18, 2872) consider it not improbable that K.'s "hydroxygluconic acid" is identical with their 2-ketogluconic acid, which yields arabinose on fermentation, but K. has been unable to obtain any arabinose by the action of yeast on his acid. Under the conditions under which H. and T. obtain their "osazone," K. obtained from the Ca salt of his acid only the very difficultly soluble phenylhydrazone of the salt, and from the free acid chiefly resinous products. VII. *Preparation of β -glucoheptone lactone.* Fischer's method (*Ann.* 270, 78 (1892)) can be materially simplified

and improved; the sirup drained from the α -lactone is dild. with 2-2.5 parts H_2O , treated at 35° with the calcd. amt. of brucine (detd. by titration of an aliquot) and allowed to stand 2 days. The soln. of the glucoheptonic acid obtained from the brucine salt (through the Ba salt) is so pure that on concn. (not above 50°) it begins to cryst. on the H_2O bath and the thin sirup, soon after cooling, solidifies almost completely, forming only the long needles of the β -lactone. VIII. A monoacetyl-*d*-galactonic acid, m. 160° , is obtained from galactonic acid, AcOH and concd. HNO_3 or HCl allowed to stand a long time at room temp. IX. The supposed *l*-galacturonic lactone semicarbazone, $C_7H_{11}O_6N_3 \cdot H_2O$, m. 189° , obtained by treating with $H_2NCONHNH_2 \cdot HCl$ the product of the oxidation of *d*-galactonic acid (I) with HNO_3 proved to be the semicarbazone, $C_7H_{10}O_7N_3$, of I, formed from the I which had escaped oxidation; refluxed in *N* HCl it gives I, and it is also obtained from I with $H_2NCONHNH_2 \cdot HCl$ and NaOAc in H_2O . *l*-Mannonic acid under the same conditions yields no difficultly sol. product, but the corresponding oxidation product, the double lactone of *l*-mannosaccharic acid, in concd. AcOH with NaOAc and $H_2NCONHNH_2 \cdot HCl$ yields the monosemicarbazide, $C_7H_{11}O_7N_3$, m. 193° , identical with the product previously supposed to be the uronic acid deriv. The true nature of the products formerly obtained from hediosite and isosaccharin after oxidation with HNO_3 was not cleared up so satisfactorily; the 2 substances, to be sure, give cryst., difficultly sol. products, as in the oxidation expts., when treated with $H_2NCONHNH_2 \cdot HCl$ and NaOAc but only in vanishingly small amts.; on the other hand, *i*-pentahydroxypimelic acid (the oxidation product of hediosite) forms no trace of a difficultly sol. $H_2NCONHNH_2$ deriv. X. The observations recorded under IX above of course materially diminished the hope of making the uronic acids more readily available by the $Br-Na_2CO_3$ method; below are some expts. which had already been made along these lines. Crystd. I (30 g.) + 3 parts H_2O + 25 g anhyd. Na_2CO_3 with 66 cc Br gave in 2 hrs. an abundant crop of the difficultly sol. Na salt, $C_6H_{11}O_7Na \cdot 2H_2O$, of unchanged I; soly. (anhyd.) in H_2O , 1:8.49. If in the oxidation 6 parts H_2O is used originally instead of 3, no salt of I seps. but the soln. contains large amts. of it, together with considerable mucic acid; Fehling detns. showed that only about 12% of the I has been converted into a reducing substance (perhaps *l*-galacturonic acid). XI. The following observations may prove of value in future work looking to the isolation of the uronic acids. (1) Glucuronic lactone with *p*- $O_2NC_6H_4NHNH_2$ in 50% AcOH gives the yellow hydrazone, $C_{12}H_{15}O_7N_3$, m. 224° , so difficultly sol. in boiling H_2O (contrary to the statement of Ekenstein and Blanksma, *Rec. trav. chim.* 24, 33(1905)), that it can hardly be recrystd. from this solvent but easily sol. in C_6H_6N . (2). With *p*- $BrC_6H_4NHNH_2$ in aq. AcOH *l*-mannohepturonic lactone (II) yields a cryst. product (probably the hydrazone), becomes discolored 145° , m. 165° (foaming). (3). II in aq. AcOH forms no difficultly sol. product with $BzNHNH_2$. (4). With *o*- $MeC_6H_4NHNH_2$ it forms yellow leaves difficultly sol. in H_2O but soon darkening. (5). *l*-Mannolactone with aq. $NH_2OH \cdot H_2O$ (0.126 g. per cc.) at room temp. gives the *hydrazide*, m. 161° , soly. in H_2O about 1.15; with *d*-gluconic acid nothing seps. and evapn. of the soln. yields a sirup which does not cryst.; I forms a thick cryst. mass; *l*-arabonic lactone forms no deposit in 5 hrs. but the sirup remaining on evapn. slowly solidifies; α - and β -glucoheptone, glucuronic and ketorhamnone lactones and *d*-saccharic and *i*-pentahydroxypimelic acids yield no crystals directly; the double lactone of *l*-mannosaccharic acid forms a cauliflower-like mass sepg. from H_2O in crusts of small needles, m. 182° (foaming); *l*-mannohepturonic lactone yields a cryst. magma which, however, slowly disappears completely in the course of 6 hrs. and after moderate spontaneous evapn. a 2nd sepn. (structureless spherules) and finally complete solidification occur. XII. The Fehling reducing action of the double lactone of "meta-" or *l*-mannosaccharic acid is about 25% that of glucose; with I and NaOH, it uses up 4 atoms I; in 2 mols. dil. NaOH with NaHg it slowly absorbs H and gradually loses its power to reduce Fehling soln.; in 2 mols. dil. KOH with KCN and in excess of hot dil. alkali it undoubtedly forms new substances.

C. A. R.

Structure of the normal monosaccharides. III. Rhamnose. E. I. HIRST AND A. K. MACBETH. *J. Chem. Soc.* 1926, 22-6; cf. C. A. 19, 1409.--Trimethyl- α -methyl-rhamnoside, b_D 101° , n_D^{15} 1.4415, results from a mixt. of α - and β -Me rhamnosides or from rhamnose, Me_3SO_4 and NaOH, followed by Ag_2O and MeI. Hydrolysis with 8% HCl at 90° gives trimethylrhamnose, b_D 141° , n_D^{15} 1.4565, which is oxidized by HNO_3 at 85° to *l*-arabotrimethoxyglutaric acid, isolated as the *di*-Me ester, b_D 135° , b_D 143° , n_D^{20} 1.4350, $[\alpha]_D$ 47.6° (MeOH, *c* 1.706). The Na salt showed $[\alpha]_D$ 25° . These facts indicate the amylene-oxidic structure for trimethylrhamnose, α - and β -Me rhamnosides and probably for rhamnose itself.

C. J. WEST

is unstable. II boiled 1 hr. in EtOH with concd. HCl gave 2,4,6-trinitrophenylurea (picrylurea), yellow, m. 201–3° (decompn.). E. J. WITZEMANN

Action of thiosemicarbazide on some aromatic nitro compounds. MICHELE GIUA AND RODOLFO PETRONIO. *Gazz. chim. ital.* 55, 665–74 (1925).—In extending the study of the labile NO₂ group (G. and Ruggeri, C. A. 17, 3865, 235; 18, 1479) the action of H₂NCSNHNH₂ (I) on aromatic NO₂ compds. was studied. 5 g. 2,4-(O₂N)₂C₆H₃Cl (II) in 80 cc. 95% EtOH warmed 3 hrs. on the H₂O bath with 4.5 g. I sepd. 2,4-dinitrophenyl-β-thiosemicarbazide, (O₂N)₂C₆H₃NHNHCSNH₂ (III) or (O₂N)₂C₆H₃NHNHCSNH₂ (SH):NH (IV), yellow, m. 210° (decompn.). 10 g. II in 50 cc. EtOH + 4.5 g. I + 6.7 g. NaOAc heated on the H₂O bath gave yellow [2,4-(O₂N)₂C₆H₃]₂S, m. 192–3°. 5 g. picryl chloride in 30 cc. EtOH with 3.7 g. I for 0.5 hr. on the H₂O bath gave 2,4,6-trinitrophenyl-β-thiosemicarbazide (or picryl-β-thiosemicarbazide) (V), m. 183–4° (decompn.). 2.4 g. V in 30 cc. EtOH with an excess of 20% FeCl₃ gave a ppt. of what is probably picrylazothiocarbamide 2,4,6-(O₂N)₃C₆H₂N:NCSNH₂ (VII), m. 166° (decompn.). β-Trinitrotoluene (VIII) with I gave 2,4-dinitro-*m*-tolyl-β-thiosemicarbazide (IX) (1 of 2 formulas like III and IV), yellow, m. 203–4°. When I and VIII are heated in H₂O in the ratio of 1:1 2,6,2',6'-tetranitro-5,5'-dimethyldiphenyl sulfide (X) mixed with IX is pptd. On crystg. from AcOH X seps. as yellow needles, m. 222°. X is not attacked even by fuming HNO₃, while the sulfide obtained from γ-MeC₆H₄(NO₂)₃ is transformed into the sulfoxide (C. A. 17, 3865). γ-MeC₆H₄(NO₂)₃ in EtOH with I gives 4,6-dinitro-*m*-tolyl-β-thiosemicarbazide (XI) (1 of 2 formulas like III and IV), yellow, m. 188° (decompn.). XI reacts easily in the cold with FeCl₃, giving a mixt. of XI, its oxidation product (XII) and 4,6,4',6'-dimethyldiphenyl disulfide (XIII), red, m. 265°. XIII is the main product when I and γ-MeC₆H₄(NO₂)₃ react in equimol. amts. in the presence of EtOH. E. J. WITZEMANN

Organic molecular compounds. VII. Azoxybenzene and aromatic nitro derivatives. MICHELE GIUA AND GUIDA GUASTALLA. *Gazz. chim. ital.* 55, 646–52 (1925).—Recently Meisenheimer (C. A. 14, 2793) described addn. compds. of aromatic poly nitro derivs. with Ph₂N₂O. The f. p. diagrams of 5 such systems are described in the paper. In the system α-(O₂N)₂C₆H₃Me–Ph₂N₂O an addn. compd., m. 64°, of 3 mols. of the 1st and 2 of the latter is formed. The equil. curve shows 2 max., of which 1 due to an anomalous reaction caused by the slowness with which the above compd. is formed. The eutectic between the compd. and Ph₂N₂O solidifies at 26.7°; that between the compd. and α-(O₂N)₂C₆H₃Me solidifies at 53.7°. The system β-(O₂N)₂C₆H₃Me–Ph₂N₂O shows a simple eutectic at 25% of the 1st compd. that solidifies at 25°. The system γ-(O₂N)₂C₆H₃Me–Ph₂N₂O shows a simple eutectic at 35% of the 1st compd. that solidifies at 22°. The system 2,4-(O₂N)₂C₆H₃Me–Ph₂N₂O shows a eutectic at 31.3% of the 1st compd. that solidifies at 16°. The system 2,4-(O₂N)₂C₆H₃Me–Ph₂N₂O shows a simple eutectic at 42% of the 1st compd. that solidifies at 16°. VIII. Azo compounds and aromatic nitro derivatives. M. GIUA AND GIULIO REGGIANI. *Ibid* 652–61; cf. Hofmann and Kirmreuther, C. A. 4, 2801.—One mol. Ph₂N₂ forms a mol. addn. compd. with 2 mols. α-(O₂N)₂C₆H₃Me that m. about 65°. The system Ph₂N₂–2,4-(O₂N)₂C₆H₃Me shows a eutectic at 49.15% of the former compd. that solidifies at 39.6°. The system Ph₂N₂–*p*-O₂NC₆H₄Me shows a single eutectic at 46% of the former compd. that solidifies at 28.6°. The system Ph₂N₂–*m*-C₆H₄(NO₂)₂ shows a eutectic at 56.2% of the 1st compd. that solidifies at 46.5°. The system *p*-H₂NC₆H₄:N:NPh–*p*-O₂NC₆H₄Me shows a eutectic at about 30% of the 1st compd. that solidifies at 34.4°. Equimol. amts. of *p*-H₂NC₆H₄:N:NPh and *m*-C₆H₄(NO₂)₂ give an addn. compd. that m. about 86°. The system *p*-H₂NC₆H₄:N:NPh–*p*-O₂NC₆H₄Cl shows a eutectic at 41.5% of the 1st compd. that solidifies at 53.8°. 1 mol *p*-Me₂NC₆H₄:N:NPh combines with 2 mols. of α-(O₂N)₂C₆H₃Me giving an addn. compd. that m. 82°. The eutectic between the compd. and the 1st component lies at 77.2°; that with the 2nd component at 73°. The system *p*-Me₂NC₆H₄:N:NPh–2,4-(O₂N)₂C₆H₃Me shows a eutectic at 34% of the 1st compd. that solidifies at 52.7°. The system *p*-Me₂NC₆H₄:N:NPh–*p*-O₂NC₆H₄Me shows a eutectic at 30% of the 1st compd. that solidifies at 40.8°. The system *p*-Me₂NC₆H₄:N:NPh–*m*-C₆H₄(NO₂)₂ shows a eutectic at 45.3% of the 1st compd. that solidifies at 63°. E. J. WITZEMANN

Influence of sulfur on the color of azo dyes. Further investigation. G. D. PALMER AND E. E. REID. *J. Am. Chem. Soc.* 48, 528–32 (1925); cf. C. A. 18, 2877.—The influence of S and of the SO₂ group on the color of azo dyes has been further studied by prep. the *meta* series of dyes. The –S– is strongly bathochromic and the –SO₂– hypsochromic, both effects being most pronounced when the alkyl is Me. The groups arrange themselves in the order SO₂Me < Me < OMe < SMe in the *m*- as in the *p*-series, but the bathochromic effect of S is not as distinct or as intense in the *m*- as in the *p*-position.

Alkyl ethers of m-acetylaminothiophenyl: Me, m. 75°; Et, oil, d_{25}^{25} 1.0360; Bu, oil, d_{25}^{25} 1.0101; benzyl, m. 74.1°; the yields were 49, 50, 64 and 50%, resp. Refluxed with concd. HCl in EtOH, there results the HCl salts of the *m*-aminothiophenol alkyl ethers: Me, 69% yield; Et, 82%; Bu, 87%; benzyl, 95%. *m*-Acetylaminophenylalkyl sulfones: Me, m. 137°, 85% yield; Et, m. 96°, 86%; Bu, oil, d_{25}^{25} 1.3727, 83%; benzyl, m. 134.2°, 94%. Hydrolysis with HCl-EtOH gave the corresponding HCl salts of the *m*-aminophenyl alkyl sulfones: Me, 59%; Bu, 57%; benzyl, 96%. The colors of the dyes prepd. from R-salt are given.

C. J. WEST

p-Chloromercuribenzoic acid and related compounds. F. C. WHITMORE AND GLADYS E. WOODWARD. *J. Am. Chem. Soc.* **48**, 533-6 (1926).—Oxidation of 100 g. crude p -ClHgC₆H₄Me with KMnO₄ in dil. NaOH gives 90% of *p*-chloromercuribenzoic acid (I), amorphous, which could not be purified; with I in EtOH it gives 95% *p*-IC₆H₄CO₂H. Refluxed in dil. EtOH-NaOH until soln. is practically complete, there results 73% of Na *p*-hydroxymercuribenzoate (II), lustrous plates. Boiling I with Na₂CO₃ gives the Na salt, hard, granular crystals. II and NaI in H₂O give Na *p*-iodomercuribenzoate, large plates; the IHg linkage is very stable; the *p*-bromo compd. was prepd. in a similar manner. I and SnCl₂ in excess of NaOH give 60% of *p*-mercuribisbenzoic acid, readily sol. in NaHCO₃; Na salt very sol. in cold H₂O. PCl₅ in CHCl₃ or SOCl₂ gives the chloride, from which the Bu ester, m. 170°, is obtained in 56% yield. C. J. W.

Organic bismuth compounds. I. Preparation of tricarboxytriphenylbismuth dichlorides and certain nitrotriaryl bismuth compounds. J. V. SUPNIEWSKI AND ROGER ADAMS. *J. Am. Chem. Soc.* **48**, 507-17 (1926).—By extg. the black ppt. from the reaction of BiCl₃ and RMgX with CCl₄ or CHCl₃, R₃Bi are obtained in 30-65% yields. *Tri-o-anisyl bismuth*, m. 169-70°. The dihalides were prepd. by passing Cl into a CCl₄ soln. or with 10% Br-CCl₄. *Tri-m-tolyl bismuth dichloride*, m. 132-3°; *dibromide*, m. 52°, could not be recrystd. and decomps. quickly in the air. The tri-*o*- and *p*-anisyl compds. appear to be very unstable towards halogens. Heating the dihalides with glacial AcOH gives the diacetates. *Triphenylbismuth diacetate*, m. 152-3°; by boiling HCl this gives the corresponding dichloride. Oxidation of (*o*-MeC₆H₄)₃-BiCl₂ in AcOH with CrO₃ gives 15% of *tri-o-carboxytriphenylbismuth dichloride*, m. 157-9°. The *p*-deriv., m. 130°, results by the use of KMnO₄ or CrO₃; the alk. soln., pptd. by EtOH or Me₂CO, gives the corresponding salt; on standing decompn. occurs. *Tri-p-carbomethoxytriphenylbismuth dichloride*, m. 103°; the yield is poor as Bi ppts. on warming with MeOH. The dihalides in Me₂CO, treated with AgNO₃ in 50% EtOH, give the corresponding dinitrates. *Trinitrotriphenylbismuth dinitrate*, pale yellow, explodes at about 147°. Crystn. from AcOH gradually replaces the NO₂ radical by the Ac radical. HCl in Me₂CO gives the *dichloride* (I), m. 132-4°. *Trinitrotri-p-tolylbismuth dinitrate*, explodes about 160°; the *dichloride*, m. 156°. *Trinitrotri-o-tolylbismuth dichloride*, m. 149-50°, decomp. on standing. *Trinitrotri-p-carbomethoxytriphenylbismuth dinitrate*, explodes about 150-60°; boiling with HCl gives *trinitrotri-p-carboxytriphenylbismuth dichloride*, m. 250-60° (decompn.). Reduction of I at 0° with Na₂S₂O₄ gives *trinitrotriphenylbismuth*, m. 121°, decomp. on standing. *Trinitrotri-p-tolylbismuth*, m. 126°. Sulfonation of tri-*o*-tolylbismuth dichloride gave a product which is apparently hydrolyzed most readily by H₂O and alkali so that the final product is [Me-(OH)C₆H₃]₃Bi(OH)Cl, m. 154°. PhN₂Cl and BiCl₃ give an addn. product, explodes about 120°. *o*-Bromobenzyl methyl ether, b_{748} 225°; the *p*-deriv., b_{730} 127°, b_{730} 201°. No Grignard reagent could be formed from them.

C. J. WEST

Cyclic organometallic compounds. I. Compounds of tellurium. H. D. K. DREW. *J. Chem. Soc.* 1926, 223-32.—TeCl₄ (23.8 g.), 18.7 g. Ph₂O and 15 cc. dry CHCl₃, heated 26 hrs., give 90% of *p*-phenoxyphenyltelluriumtrichloride, PhOC₆H₄TeCl₃ (I), pale yellow, softens about 154°, m. 156-7°. There also results about 0.5 g. of *p,p'*-diphenoxydiphenyltelluriumdichloride, m. 157-8°, best obtained by heating 3.9 g. I and 1.7 g. Ph₂O at 140-65° for 6 hrs. in an atm. of N; this is unchanged at 210° after 1 hr., is unchanged by cold aq. KOH but decompd. by boiling, giving Ph₂O. Reduction of I in ice-cold H₂O with K metabisulfite gives a quant. yield of *p,p'*-diphenoxydiphenyl ditelluride, bronzed brownish violet or purplish red, softens 85°, m. 87-8°, mol. wt. in freezing C₆H₆, normal. Solns. exposed to the air slowly deposit an amorphous oxide; Br gives a yellow bromide, m. about 180°; warm HNO₃ ultimately gives (*p*-O₂NC₆H₄)₂O. Heating I at 150-200° for 4.75 hrs. or heating TeCl₄ and Ph₂O at 100-240° during 13 hrs., gives 10,10-dichlorophenoxitellurine, m. 265°; at 100° the cryst. form is yellow but becomes colorless on cooling. It is slowly hydrolyzed by boiling H₂O to an oxide. Reduction gives phenoxitellurine, lemon-yellow to orange, m. 78-9°, with a delicate floral odor; it can be vaporized unchanged; the cold concd. H₂SO₄ soln. is deep purplish red. It is

stable towards hot concd. HCl or dil. aq. NaOH. Warm concd. HNO_3 gives the 10,10-dinitrate, decomp. about 258° . The dibromide, bright yellow, decomp. 290° ; the diiodide, red, decomp. about 270° . The action of heat upon mixts. of TeCl_4 and Ph_2O in various proportions is discussed. C. J. WEST

Constitution of tribromophenol bromide and its congeners. W. M. LAUER. *J. Am. Chem. Soc.* **48**, 442-51(1926).—The tetrabromocyclohexadienone formula of Thiele and Eichwede (*Ber.* **33**, 673(1900)) for the compd. resulting by the action of Br on $\text{Br}_3\text{C}_6\text{H}_2\text{OH}$, is improbable. The "hypobromite" formula of Benedikt (*Ann.* **199**, 127(1879)) accounts for the facts introduced if there is postulated a partial rearrangement of trihalogenated phenol chlorides which contain Br in the *p*-position to the isomeric trihalogenated phenol bromides. 4,2,6- $\text{BrCl}_2\text{C}_6\text{H}_2\text{OH}$ and Cl give a compd. $\text{C}_6\text{H}_2\text{BrCl}_3\text{O}$, decomp. about 114° (depending upon the rate of heating); Br and $\text{ClBr}_2\text{C}_6\text{H}_2\text{OH}$ give the compd. $\text{C}_6\text{H}_2\text{ClBr}_3\text{O}$, decomp. about 115° ; Cl and $\text{Br}_3\text{C}_6\text{H}_2\text{OH}$ give an isomeric compd., decomp. about 131° . The action of EtOH upon these compds. is described. The original should be consulted for the theoretical discussion. C. J. WEST

Nitration of *m*-bromophenol. H. H. HODGSON AND F. H. MOORE. *J. Chem. Soc.* **1926**, 155-61; cf. *C. A.* **19**, 2937.—Mononitration of *m*- $\text{BrC}_6\text{H}_4\text{OH}$ with NaNO_2 and H_2SO_4 gives a mixt. of the 6- NO_2 deriv., m. 42° (volatile with steam) (Me ether, m. 85.5° ; benzoate, cream-colored, m. 104° ; Na salt, scarlet needles) and the 4- NO_2 deriv., yellowish white, m. 131° (Me ether, m. 45° ; benzoate, cream-colored, m. 102° ; Na salt, amber needles). HNO_3 in oleum gives the 2-nitro deriv., bright yellow, m. $65-7^\circ$; Na salt, red needles; Me ether, m. 73° ; benzoate, m. 133° ; it forms a very labile, colorless hydrate, m. 35° ; the yellow form reverts to the hydrate in moist air; the sensitiveness of the compd. is such as to make it an approx. indicator of atm. humidity. The anhyd. yellow variety of 3-chloro-2-nitrophenol, m. $45-7^\circ$; the hydrate, with 1 H_2O , m. $37.5-8^\circ$, this hydrate is much more stable in air than that of the Br deriv. *m*- $\text{BrC}_6\text{H}_4\text{OH}$ and 90.5% HNO_3 in an equal vol. of AcOH give the 4,6-(NO_2)₂ deriv., m. 92° ; this also results from the 6- or 4- NO_2 deriv. and mixed acid (15 vols. 98% H_2SO_4 , 12 vols. 70% HNO_3 and 9 vols. H_2O) and by boiling 1,3,4,6- $\text{Br}_2\text{C}_6\text{H}_2(\text{NO}_2)_2$ with aq. Na_2CO_3 6 hrs. Ag salt, yellow gelatinous ppt gradually changing to a red cryst. form; in aq. NH_3 a yellow cryst. form results. The 2- NO_2 deriv. in the mixed acid gives the 2,6-dinitro deriv., m. 131° ; a small amt. is obtained from the 6- NO_2 deriv. in oleum (27% SO_3) after 3 hrs. at 10° by nitrating with 90.5% HNO_3 in oleum. Ag salt, red. The 2,4-dinitro deriv. forms a yellow Ag salt. The 2,6- and 2,4-(NO_2)₂ derivs. may be sep'd by conversion into the Ag salts and digestion with NH_4OH , the 2,6-(NO_2)₂ salt being soluble in cold NH_4OH . Concd. NH_4OH converts both derivs. into 2,4,1,3-(O_2N)₂- $\text{C}_6\text{H}_2(\text{NH}_2)_2$. NaOH gives 2,4,1,3-(O_2N)₂- $\text{C}_6\text{H}_2(\text{OH})_2$. 3,2,4,6- $\text{Br}(\text{NO}_2)_3\text{C}_6\text{H}_2\text{OH}$, m. 149° . 3-Bromo-2,5,6-trinitrophenol, m. 146° ; the yellow Ag salt is sol. in H_2O but insol. in NH_4OH . K 3-bromo-2,5,6-trinitrophenol-4-sulfonate, yellow, explodes on heating. C. J. WEST

Reduction with active charcoal of organic substances containing oxygen. G. STADNIKOV, N. GAVRILOV AND A. VINOGRADOV. *Ber.* **58B**, 2428-9(1925).—C deposited on finely divided Fe is extraordinarily active and at a relatively low temp. (430°) is burned to CO and CO_2 at the expense of the O of cresols, which are thereby reduced to PhMe. Asbestos is soaked with Cl-free $\text{Fe}(\text{NO}_3)_3$, pressed out, treated with 10% NH_4OH , washed, dried and filled into a tube which is heated 3-4 hrs. at $460-70^\circ$ in a current of H; the temp. is raised to $480-90^\circ$ and *p*-cresol is added at the rate of 3-5 drops per min. while a slow current of H is passed through the tube; the cresol decomp. into H, CO and C which is deposited on the Fe; when CO_2 appears in the issuing gas, the temp. is gradually dropped to 430° when the cresol can be added more rapidly (12-5 drops per min.); the issuing gas contains 10-14% CO_2 and 5-8% CO and as high as 84% PhMe can be obtained. In CO_2 instead of H a good yield of PhMe (up to 75%) can also be obtained; the issuing gas contains considerable CO, formed by reduction of the CO_2 by the C. In N, 85% PhMe can be obtained. C. A. R.

Benzoquinone dichloride. OTTO DIMROTH, EBER HANS AND KARL WEHR. *Ann.* **446**, 132-47(1925).—Benzophenone dichloride (I) (5 g.) in 25 cc. Ac_2O and 0.5 cc. concd. H_2SO_4 at 65° for 3 days yields 2,3-dichlorohydroquinol diacetate, m. 121° ; no intermediate product could be isolated. A slow acetylating agent, such as Ac_2O contg. *p*- $\text{MeC}_6\text{H}_4\text{SO}_3\text{H}$, acting for 4 weeks at 50° , gives the 2,5-dichlorohydroquinol diacetate, m. 141° . The dibromide, under all conditions, always gives the 2,5-diacetate. β -Naphthoquinone dichloride or dibromide with Ac_2O - H_2SO_4 gives the 2-Cl- or 2-Br- α -deriv. *p*-Diketocyclohexane, Ac_2O and H_2SO_4 give cyclohexane-1,1,4,4-tetraacetate (II), m. 107° , sublimes $200-20^\circ$ (partial decompn.); warming on the H_2O bath gives hydroquinol diacetate, m. 122° . II and Ac_2O contg. *p*- $\text{MeC}_6\text{H}_4\text{SO}_3\text{H}$ give cyclohexadiene-1,4-diacetate.

m. 94–5°. Reduction of I with CrCl_2 gives hydroquinol; SnCl_2 and HCl at 0° give monochlorohydroquinol, m. 104°, as does SO_2 . HI at 0° appears to give a dihydrodichlorohydroquinol, m. about 92°. Oxidation of I with KMnO_4 at 0° gives isodichlorosuccinic acid (III), m. 175°, as does toluquinone dichloride. *Acetaminoquinone dichloride*, pale yellow, m. 91°; oxidation gives III. Methoxyquinone dichloride, yellow prisms and needles, m. 144–5°; oxidation gives III. The Cl probably adds to O:C₆H₄:O in the *trans*-position. C. J. WEST

Organo-metallic compounds of aluminium. IV. Action of acid chlorides. P. LEONE. *Atti accad. Lincei* [vi], 1, 443–5 (1925), cf. *C. A.* 19, 2929. The action of BzCl on Al Et iodide in ether yields MeCHBz_2 , benzoyl ethane, a small proportion of PhCOPr , and ethane, the last probably resulting from decompn. of some of the Al Et iodide by the HCl formed during the condensation. B. C. A.

Chloro derivatives of m-hydroxybenzaldehyde. II H. HODGSON AND H. G. BEYARD. *J. Chem. Soc. 1926*, 147–55, cf. *C. A.* 19, 2040. Direct chlorination of 3- $\text{HOCH}_2\text{CH}_2\text{CHO}$ in glacial AcOH gives a little 6-Cl deriv., but principally the 2-chloro deriv. (I), m. 139.5°; catalysts have little or no effect on the reaction. The same deriv. was prepd. from 2,3- $\text{O}_2\text{N}(\text{HO})\text{C}_6\text{H}_3\text{CHO}$ through the diazo compd. Oxidation gives 2-chloro-3-methoxybenzoic acid, m. 160°. I gives an *Ac* deriv., m. 62°, a *Bz* deriv., m. 88°, an *oxime*, m. 149°, a *p*-nitrophenylhydrazone, orange-red, m. 244–5°, a semicarbazone, pale yellow, m. 236–7°. The 4-chloro deriv. (II), m. 121°, yields an *oxime*, m. 126° (hydrate decomps. 106–10°), *p*-nitrophenylhydrazone, violet-red, m. 226–7°, and semicarbazone, pale yellow, m. 238–9°. The 6-chloro deriv. (III), m. 111°, was obtained in very poor yield through the 6- NO_2 deriv. and also by nitration of 2- $\text{ClC}_6\text{H}_4\text{CHO}$, reduction and diazotization; 2-chloro-5-aminobenzaldoxime, m. 159–60°. III yields an *oxime*, m. 146–7°, also crystg. with 1 H_2O from dil. EtOH ; *p*-nitrophenylhydrazone, red, m. 250–1°; semicarbazone, pale yellow, m. 236°. Chlorination of I, m- $\text{HOCH}_2\text{CH}_2\text{CHO}$ or III gives the 2,6-dichloro deriv., m. 140°; *oxime*, m. 174–5°; *p*-nitrophenylhydrazone, deep orange-red, m. 205–6°. II gives the 2,4-dichloro deriv., m. 141°; *oxime*, m. 188°; *p*-nitrophenylhydrazone, orange-red, m. 277–8°. The 2,4,6- Cl_3 deriv., m. 114°; Na salt, pure yellow; *oxime*, m. 174°; *p*-nitrophenylhydrazone, yellow-orange, m. 272–3° (decompn.). 6-Nitro-3-methoxybenzoic acid, m. 255° (Rieche, *Ber.* 22, 2347 (1889), gives 132–3°); *Ag salt*. 2-Chloro-3-methoxybenzaldehyde, m. 56°; *oxime*, m. 130.5°; *p*-nitrophenylhydrazone, old gold, m. 226–7°; *p*-bromophenylhydrazone, pale yellow, m. 155–6°; *t*-chloro deriv., m. 52°, *oxime*, m. 98–9°, *p*-nitrophenylhydrazone, old gold, m. 251°; *p*-bromophenylhydrazone, pale pink, m. 134°. 6-Chloro deriv., m. 62°; *oxime*, m. 101.5°; *p*-nitrophenylhydrazone, old gold, m. 229°; *p*-bromophenylhydrazone, pale yellow, m. 100°. 2,6-Dichloro deriv., m. 102°; *p*-nitrophenylhydrazone, old gold, m. 214–5°; oxidation gives the corresponding acid, m. 149.5°. 2,4-Dichloro deriv., m. 82°; *p*-nitrophenylhydrazone, old gold, m. 258–60°. 2,4,6-Trichloro deriv., m. 76°; the corresponding acid, m. 109° (Zincke, *Ann.* 261, 239 (1891)) gives 90°. The chloro-3-hydroxybenzaldehydes all have very pronounced stannatory properties, which are most marked in the 2,6- and but slightly less so in the 2,4,6-compd. For the mono-Cl derivs. the order is 6-, 2- and 4-. The property is comparatively feeble in the last compd. and thus is indicated its dependence on *o*-substitution. The property vanishes on methylation but the MeO compds. have a hawthorn-like odor which in turn vanishes when these are oxidized to the acids. All these compds. attack the moistened skin, producing painful blisters. C. J. WEST

New synthesis of o-acetoveratrole. F. MAUTHNER. *J. prakt. Chem.* 112, 57–60 (1926).—2,3- $\text{HO}(\text{MeO})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ (50 g.) and 134 cc. Me_2SO_4 give 45 g. 2,3-(MeO)₂- $\text{C}_6\text{H}_3\text{CO}_2\text{H}$, which yields 34.7 g. Me ester; with 19 g. AcOH and 4.2 g. Na there results 17 g. *Et* 2,3-dimethoxybenzoylacetate, pale yellow oil, which yields a pyrazolone deriv., m. 125–6°. Boiled 12 hrs. with 25% H_2SO_4 , 17 g. ester gives 4 g. 2,3-(MeO)₂- $\text{C}_6\text{H}_3\text{Ac}$, whose *p*-nitrophenylhydrazone, red, m. 155–6°. C. J. WEST

New synthesis of o-vanillin and o-veratraldehyde. F. MAUTHNER. *J. prakt. Chem.* 112, 60–4 (1926).—2,3- $\text{HO}(\text{MeO})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ (25 g.) and 11.2 g. ClCO_2Me in 36 g. PhNMe_2 and 125 g. C_6H_6 in a cooling mixt. give 16.5 g. carbomethoxyguaicol-*o*-carboxylic acid, m. 145–6° (decompn.); FeCl_3 gives a very pale color. The acid (12 g.) and 13.8 g. PCl_5 in 25 cc. CHCl_3 give 11 g. of the chloride, m. 43–4°. Reduction of 5 g. of the chloride in 15 cc. PhMe with 2 g. Pd-BaSO_4 catalyst at 110° for 6 hrs., followed by sapon., gives 2 g. *o*-vanillin, whose *p*-nitrophenylhydrazone, red, m. 217–8°. 2,3-Dimethoxy-1-benzoyl chloride, b_p 142–3°, m. 54–5°, results in 18 g. yield from 20 g. of acid; the amide, m. 93–4°. Reduction of 5 g. of the chloride as above gives 2.1 g. *o*-veratraldehyde, whose *p*-nitrophenylhydrazone, m. 205–6°. C. J. WEST

Preparation, hydrolysis and reduction of the fluoro-, chloro- and bromo-benzyl

bromides. J. B. SHOESMITH AND R. H. SLATER. *J. Chem. Soc.* 1926, 214-23; cf. *C. A.* 19, 474.—The $\text{ClC}_6\text{H}_4\text{CH}_2\text{Br}$ were prepd. from the corresponding $\text{ClC}_6\text{H}_4\text{Me}$ through the $\text{ClC}_6\text{H}_4\text{CHCl}_2$, $\text{ClC}_6\text{H}_4\text{CHO}$ and $\text{ClC}_6\text{H}_4\text{CH}_2\text{OH}$. *o*-Chlorobenzyl bromide, b_p 102°. *m*-Deriv., b_{10} 109°. The $\text{BrC}_6\text{H}_4\text{CH}_2\text{Br}$ were prepd. by passing a stream of air through Br into boiling $\text{BrC}_6\text{H}_4\text{Me}$; the *o*-deriv., m. 31°; *m*-deriv., m. 40°; *p*-deriv., m. 63°. With KI they yield the *bromobenzyl iodides*: *o*-deriv., m. 47°; *m*-deriv., m. 42°; *p*-deriv., m. 73°. *o*-Fluorobenzyl bromide, b_{15} 84-5°; *m*-deriv., b_{12} 77°; *p*-deriv., b_{15} 85°. Results are given for hydrolysis and reduction of the bromides. The order in which the atoms or groups affect the reactivity of the Br towards hydrolyzing agents in a general way is OMe, Me, F, Cl, Br, CO_2H , NO_2 , ranging from the strongly enhancing MeO group to the strongly retarding NO_2 group and towards HI is OMe and Me, Cl, Br, CO_2H and F. In the latter case only the MeO and the Me group have an appreciable general influence on the reduction velocity. The alternating and steric effects also are discussed. C. J. WEST

Organic peroxides. VIII. Some additional reactions which apparently proceed according to the R.H. scheme. H. GELISSEN AND P. H. HERMANS. *Ber.* 58B, 2396-9 (1925); cf. *C. A.* 19, 2484.—Attention is drawn to some reactions described in the literature which seem to support the validity of G. and H.'s R.H. scheme. v. Lippmann with $\text{MeCH}:\text{CHEt}$ (I) and BzO_2H (*Monatsh.* 5, 559(1884)) obtained CO_2 , BzOH , "Amylwasserstoff" (II) and an oil (III) (C 75.4, H 8.0%) which on hydrolysis with alc. KOH yielded BzOK and a liquid which he called "diamylene oxide" (IV). G. and H. believe his II was C_6H_6 and the IV was $\text{Et}_2\text{C}:\text{CMcCOEt}$ (V) and that the reaction proceeds chiefly according to the scheme $\text{I} + \text{Bz}_2\text{O}_2 \rightarrow \text{BzOCet}:\text{CHMe}$ (VI) + $\text{PhH} + \text{CO}_2$. The VI (C 75.1, H 7.4%) on hydrolysis yields BzOH and the enol, which at once rearranges into Et_2CO , and this, under the influence of the alc. KOH, gives V, whose compn. and vapor d. agree well with the values found by v. L. for his IV. The decompn. of $(\text{PhSO}_2)_2\text{O}_2$ by H_2O at 61° observed by Fichter and Stocker (*C. A.* 19, 980) can be explained fully as well as proceeding according to the scheme $\text{PhSO}_2\text{O.O.SO}_2\text{Ph} + \text{H.OH} \rightarrow \text{PhSO}_2\text{OH} + \text{PhOH} + \text{SO}_3$. C. A. R.

Ring systems with *p*-linkages. GUSTAV HELLER AND SIEGFRIED GOTTFRIED. *J. prakt. Chem.* 111, 368-72(1925).—*p*-Aminobenzoic acid hydrazide (I) and BzCl in $\text{C}_6\text{H}_5\text{N}$ give *p*-benzoylamino benzoic acid benzoylhydrazide, m. 262°; it is unchanged by heating at 260°. Heating with Ac_2O does not cause ring formation but the introduction of an Ac group, giving the compd. $\text{C}_{22}\text{H}_{19}\text{O}_4\text{N}_3$, m. 226°. Heating I at 220-80° causes the loss of NH_3 and the formation of *p*-benzoylpyrazolone, $(\text{C}_7\text{H}_5\text{ON}_2)_x$, crystg. with 0.5 H_2O , pale brown, m. 312°; *Ac* deriv., m. 340°. The HCl soln., treated with NaNO_2 , gives with Na_2CO_3 a red ppt., sol. in excess. *Et p*-hydrazinobenzoate, yellow, m. 118°; *Ac* deriv., m. 148-9°. C. J. WEST

Action of ammonia on ethyl cinnamate. K. STOSIUS AND E. PHILIPPI. *Monatsh.* 45, 569-72(1925).—By keeping a mixt. of Et cinnamate (14 g.) and liquid NH_3 (5 cc.) in a sealed tube at the ordinary temp. for 4 months, the following products were obtained: cinnamamide, m. 142°; $\text{PhCH}(\text{NH}_2)\text{CH}_2\text{CO}_2\text{H}$, m. 221-2° (slow heating) or 231° (rapid heating); and β -amino- β -phenylpropionamide, m. 88-110° [oxalate (+2 H_2O)], m. 193° (anhyd.)], which loses NH_3 when boiled with water, yielding cinnamamide. B. C. A.

Polymerization and depolymerization by light of different wave lengths. II. α - and β -trans-Cinnamic acids, *allo*-cinnamic acid and their dimers. HANS STOBBE AND ALICE LEHFELDT. *Ber.* 58B, 2415-27(1925); cf. *C. A.* 18, 2503.—I. *Photoisomerizations and photopolymerizations of the rhombic α -trans-cinnamic acid and the *allo*-acid 68°*. The α -trans-acid, m. 133° (I), exposed 6 months to sunlight in H_2O gave 90.5% I and 9.5% of the *allo*-acid (II); in $\text{H}_2\text{O} + \text{HCl}$, 75.0 and 25.0%; II in H_2O gave 14.0% I and 86.0% II; in $\text{H}_2\text{O} + \text{HCl}$, 29.0 and 71.0%. In suspensions instead of solns., the isomerization is accompanied by polymerizations; below are the % yields of I, II, α -truxillic acid (III), β -truxinic acid (IV) and resin, resp., obtained after 6 months' exposure to sunlight. I in H_2O , 76.0, 5.0, 10.0, 9.0, —; in $\text{H}_2\text{O} + \text{HCl}$ (10:1), 35.0, 1.0, 49.0, 15.0, —. II in H_2O , 61.0, 6.5, 6.0, 20.0, 6.5; in $\text{H}_2\text{O} + \text{HCl}$, 47.0, 1.0, 5.0, 42.0, 5.0. The relative yields of I (+ resin), and III from 1 g. I exposed 4 weeks to sunlight in suspension in various mediums were as follows: 150 cc. H_2O , 85.3, 14.6; 150 cc. $\text{H}_2\text{O} + 15$ cc. HCl , 23.4, 75.0; 150 cc. $\text{H}_2\text{O} + 15$ cc. $\text{HCl} + 0.5$ g. NaCl , 25.0, 73.0; 150 cc. $\text{H}_2\text{O} + 0.5$ g. NaCl , 46.5, 53.5; in all cases, traces of II and IV also were formed. From I exposed 95 hrs. to a quartz Hg lamp (4.4 amp., 6 cm.) in H_2O suspension were obtained 88.9% I, 8.9% II and 2.2% III + IV; in $\text{H}_2\text{O} + \text{HCl}$ (10:1), 81.8, 13.6 and 4.5%, resp. II. *Photodepolymerizations of α -truxillic and β -truxinic acids*. Yields of

I, II, III, IV and resin after 500 hrs.' exposure to a quartz Hg lamp; from quartz (transparent to all rays down to 180μ), 18.2, —, 77.8, —, 4.6; in uviolet (transparent to all rays down to 270μ), 15.2, —, 82.2, —, 2.6. From IV in quartz, —, 26.8, —, 69.4, 3.8; in uviolet, —, 15.4, —, 80.2, 4.4. From III in C_6H_6 suspension in quartz, 12.0, 7.0, 63.0, 13.4, 4.6; in uviolet, 5.8, 1.8, 79.6, 9.0, 3.8; in glass (transparent to 320μ), 3.0, 0.1, 93.5, 3.4, —. From V in C_6H_6 suspension in quartz, 3.4, 9.8, 28.0, 56.6, 2.2; in uviolet, 1.4, 8.0, 18.8, 69.8, 2.0; in glass, 0.1, 2.7, 11.5, 85.7, —. From the Na salt of III in aq. soln. in quartz, 21.4, 7.1, 70.8, 0.7, —; in uviolet, 20.1, 6.7, 72.8, 0.4, —; in glass, 9.0, 0.1, 90.9, —. From the Na salt of IV in quartz, 15.1, 47.2, 0.4, 37.3, —; in uviolet, 12.1, 25.7, 0.3, 61.9, —; in glass, 3.3, 6.9, —, 89.9, —. The same results are obtained in 100 instead of 500 hrs. III. Photoisomerization and photopolymerization of β -trans-cinnamic acid. In aq. acid suspension (prepd. by adding a slight excess of HCl to a soln. of the Na salt), the β -trans-acid (V) after 5 months in winter sunshine gave 5.0% I, 37.5% IV and 57.5% resin, after 4 weeks in summer sunshine 23.5, 57.6 and 18.6%, resp. Repetition of de Jong's expts. (C. A. 16, 2683) gave the following yields of I, II, III and IV (exposure to direct sunlight, 35 hrs. in 7 days): V dissolved and repptd. only at the beginning and not covered, 50.6, 3.2, 29.2, 17.0; repptd. each day and uncovered, 26.8, 11.1, 22.7, 39.3; repptd. only at the beginning, scraped off and powd., and covered with glass, 54.6, 3.5, 28.4, 13.6; same, but not covered, 51.0, 2.9, 30.0, 16.1; powd., not repptd. (hence I) and not covered, 57.1, traces, 42.9, —. Yields of I, II, III, IV and resin from V exposed to sunlight 14 days but allowed to stand varying lengths of time in the dark after the pptn. before being illuminated: 0 hr., 29.0, 1.2, 17.1, 32.3, 20.4; 1 hr., 37.5, 1.6, 19.8, 28.1, 13.0; 2 hrs., 39.2, 1.7, 37.0, 21.7, 1.7; 24 hrs., 70.9, 1.4, 23.8, 4.2, —. Yields after 35 hrs.' exposure to a quartz Hg lamp: uncovered, repptd. 7 times, 19.7, 67.5, traces, 0.4, 12.0; repptd. once, 60.1, 28.2, 1.4, 1.4, 8.9; not repptd., 96.4, 0.4, 1.2, —, 2.0; covered with glass, repptd. once, 57.3, 2.5, 26.7, 13.3, —. Yields from freshly repptd. V exposed 175 hrs. in aq. acid suspension to the Hg lamp, 18.9, 70.40, 1.4, traces, 9.3. These results show that the metastable V is isomerized to I much more rapidly than the stable I and the II on further illumination, when the shorter ultra-violet rays are excluded, is directly polymerized to IV, which is, therefore obtained in good yield from V, while the difficultly isomerized I gives only little IV but much III (formed directly from the I). The views of de Jong as to the formation of III and IV are thus definitely disproved. Addendum. Reply to de Jong (C. A. 17, 3173).

C. A. R.

Reactions of the nitroso derivatives on unsaturated compounds. III. Dinitrones corresponding to α -diketonic acids. L. ALESSANDRI. *Gazz. chim. ital.* 55, 729-44 (1925).—The work in a previous paper (C. A. 19, 45) on the addn. of aromatic NO derivs. to C_2H_2 derivs. (tolan) is extended in this. 2.92 g. $PhC:CCO_2H$ (I) + 4.5 g. $PhNO$ in Et_2O were kept in the dark at room temp. for 10 months. $PhNO$ was still present (A., C. A. 5, 276). The Et_2O soln. was treated to sep. the products and Ph_2N_2O and unchanged I were recovered. 3.5 g. of $PhC:CCO_2Et$ + 4.5 g. $PhNO$ in enough $CHCl_3$ to dissolve them were kept in the dark at room temp. 22 days. The solvent was evapd. and the residue crystd. from $EtOH$ gave the dinitrone of an α -diketonic acid (II) $PhN(O):CPhC(CO_2Et):N(O)Ph$, m. $143-4^\circ$. II crystals in 2 forms, having different m. ps., which are mutually transformable. The structure assigned to II depends on the data of analysis, on the Au-yellow color, the development of $PhNO$ by the action of $KMnO_4$, its decompn. in sunlight (C. A. 16, 2504) and the fact that in $EtOH$ with $NH_2OH \cdot HCl$ it gives oximidophenylisoxazolone, which is a normal reaction for 2 nitronic groups (C. A. 4, 2457; 5, 276). $PhC:CCO_2Et$ with $EtO_2CC_6H_4NO$ (III) in glacial $AcOH$ gave the corresponding dinitrone, $EtO_2CC_6H_4N(O):CPhC(CO_2Et):N(O)C_6H_4CO_2Et$, m. about 185° (decompn.), the structure of which is similar to that of II, as indicated by similarity of properties. In $CHCl_3$ this result is not obtained. $PhC:CCO_2Et$ is oxidized and probably $BzCOCO_2Et$ is formed. Reduction products of III, especially considerable (p - $EtO_2CC_6H_4$) $_2N_2O$, were isolated. Similar expts. were made with p - $ONC_6H_4NMe_3$ (V), which does not react with tolan or C_2H_2 . $PhC:CCO_2Et$ with V gives what is probably $Me_2NC_6H_4N(O):CPhC(CO_2Et):N(O)C_6H_4NMe_3$, m. 164° (decompn.). This compd. was also obtained as an addn. product with 1 mol. $EtOH$. Heller, *et al.* (C. A. 16, 2686; 17, 3024) obtained such addn. products with nitrones. A. expects to continue the study of these compds. E. J. W.

Phenylalanine series. VI. Decarboxylation of tyrosine and leucine. E. WASGR. *Helvetica Chim. Acta* 8, 758-73 (1925).—An electrically heated app. is described and illustrated in which 30 g. of tyrosine (I), heated 0.5 hr. *in vacuo* at $300-10^\circ$, yielded 60-75% of the theory of tyramine (II). An inert heat-carrier proved better (cf. also Graziani, C. A. 9, 3065; 11, 792; Johnson and Daschavsky, C. A. 19, 1135; Zemlén,

Ger. pat. 389,881) A table is given of the substances tested and the yields of **II** obtained with their aid, fluorene (**III**) finally being chosen because of the high yield of **II** (96%) and the short reaction time. The closed Al-plated Fe app. used contained a stirrer operating in a Hg seal and a reflux condenser heated with superheated steam to return vaporized **III** as a liquid. 400–500 g. **I** was added in 10-g. portions every min. to 1200–1500 g. **III** at 280–90°. After 5–10 min further stirring the mixt. was cooled close to the f. p. of **III**, poured out, pulverized, boiled 2–3 times with several vols. H₂O or dil. HCl, dried and returned to the app. for the next fusion. The HCl salt (**IV**) of **II** is best purified by recrystn. from 3.75 parts of boiling NaCl-H₂O (1:3.5), followed by pressing out, washing with a little H₂O and recrystn. from alc. with addn. of Et₂O. **II** is best isolated directly from the melt by extrn. with boiling H₂O until the Millon test is indistinct, concn. *in vacuo* with the capillary connected to a supply of H₂, and distn. *in vacuo* or recrystn. from alc. or both. **IV** is best converted into **II** through the sulfite, m. 297–8° (cor.), which is decompd. with the calcd. amt. of Na₂CO₃. PhOMe is the best solvent for recrystg. **II**, but it is best purified by distn. in a high vacuum in a flask designed to avoid clogging by the sublimation or freezing of the **II**; it b₁₃ 195°, b₂ 165–7° (cor.), m. 164–4.5° (cor.). When heated by itself or with Fe filings, or as the Ba salt, leucine (**V**) yields, besides iso-AmNH₂ (**VI**), varying amts. of iso-BuCH(CO)NHCH(CH₂CHMe)₂CO)NH and iso-BuCN. Description of a typical

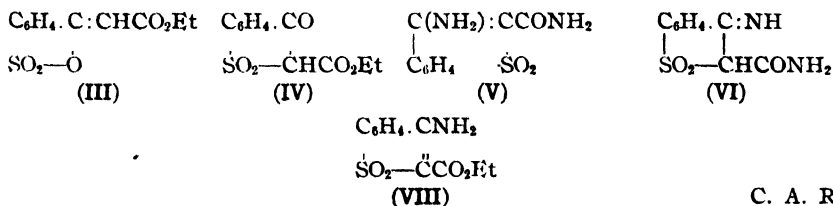

run is given. 15 g. **V**, added to 45 g. **III** at 120°, heated to 180°, and finally to 200–35° until gas evolution ceased (10 min. in all), yielded **VI** almost quant., partly as the carbonate; purified through the HCl salt. **VII. Synthesis of l-3,4,5-trihydroxyphenyl-alanine.** E. WASER, A. LABOUCHÈRE AND H. SOMMER. *Ibid* 773–9.—Schaaf and L. (C. A. 18, 1825) having published a synthesis of the *dl*-(HO)₃C₆H₂CH₂CH(NH₂)CO₂H (**I**), W. has completed his work on the extension to *l*-I (*Verh. Schweiz. Naturf. Ges.* 1921, II, 117) of W. and Lewandowski's synthesis of *l*-3,4-(HO)₂C₆H₃CH₂CH(NH₂)COOH (**II**) (C. A. 16, 81). In Johnson and Kohlmann's method (C. A. 9, 2657) for the prepn. of 3,5-dinitrotyrosine (**III**) slight modifications permitted the use of 10-g. batches; or better, 7 g. powd. tyrosine (**IV**) was stirred into 55 g. H₂SO₄ and 8 g. 65% HNO₃ at –10° during 15 min., keeping the temp. <0°, then 15 min. <10°, and chilled 20–30% NaOH was then added until a red ppt. formed, sol. in excess. After 12 hrs the ppt., stirred with 150 cc. H₂O at 35° to remove Na₂SO₄ and recrystd. from H₂O, was converted into free **III** with the calcd. amt. *N* HCl and recrystd. from H₂O; yield 4.2 g.; explodes 230° when rapidly heated. Reduction of **III** with Sn and HCl was unsatisfactory, but with Pt and H₂ in dil. HCl or H₂SO₄ for 1–2 days, concg the soln. *in vacuo* with a capillary connected to H₂, the *HCl* salt, or sulfate (**V**), hygroscopic needles, of *l*-3,5-diaminotyrosine was obtained. With BaCO₃ **V** yields a soln. of the free acid, easily oxidizable, turns red with FeCl₃, changing to violet, gives a yellow ppt. with Millon's reagent, turning brown on boiling; for [α]_D see W., C. A. 17, 1798. All subsequent manipulations were in an atm. of H₂. **V** from 6.53 g. **III** was tetrazotized in 11 g. H₂SO₄ and 11 g. H₂O with a soln. of 5.49 g. Ba(NO₃)₂, cooling with ice; added to a boiling soln. of 50 g. CuSO₄ in 50 cc. H₂O, cooled, treated with H₂S, then 100 g. BaCO₃, let stand 12 hrs., filtered, washed with boiled H₂O, freed from Ba⁺⁺, filtered in the presence of a little SO₂, and concd. dry, it yielded 1 g. *l*-3,4,5-trihydroxyphenylalanine, very hygroscopic, and sol. in H₂O contrary to S. and L. (*loc. cit.*), the aq. soln. rapidly darkening; when rapidly heated, decomp. ca. 225–30°. A table is given showing the similarity in its color reactions to those of 1,2,3-C₆H₃(OH)₃. M. HEIDELBERGER

Derivatives of *p*-carboxyphenoxylacetic acid. W. G. CHRISTIANSEN. *J. Am. Chem. Soc.* 48, 460–8 (1926).—Me *p*-carbomethoxyphenoxylacetate (**I**), m. 92–2.7°, in 49.7 g. yield from 59.5 g. of acid in MeOH-HCl. Treating **I** with concd. NH₄OH or *p*-HO₂CC₆H₄OCH₂CONH₂ with Me₂SO₄ gives *p*-carbomethoxyphenoxylacetamide (**II**), m. 164°. *p*-HOC₆H₄CO₂H and ClCH₂CONH₂ give a mixt. of *p*-carboxyphenoxylacetamide, m. 282–2.5° and a very little of *O*-*p*-hydroxybenzoylglucosylamide, m. 257–8°. **II**, heated with concd. NH₄OH under pressure, gives *p*-carbamidophenoxylacetamide, m. 261–4.5°. Nitration of 40 g. **I** with 1 mol. equiv. of HNO₃ in H₂SO₄ gives *Me* 2-nitro-4-carbomethoxyphenoxylacetate, slightly yellow, m. 125.5–7°, as the main product (16.5 g.). 0.62 g. of the 2,6-dinitro deriv., yellow, m. 118.5–9°; 3.3 g. of 2,4-(O₂N)₂C₆H₃OCH₂CO₂Me; and 1.97 g. of a *Me* ester of 2-nitro-4-carboxyphenoxylacetic acid (**IV**), m. 204–5°. Reduction of 2,4-O₂N(HO₂C)C₆H₃OCH₂CO₂H with FeSO₄ in NH₄OH gives 70% of 6-carboxy-3-keto-3,4-dihydro-1,4-benzoxazine (**III**), softens 306–7°, m. 310–4°; the *Me* ester, m. 192.5–3°, results by esterification of **III** or by the reduction of the 2,4-O₂N-(MeO₂C)C₆H₃OCH₂CO₂Me with Fe in MeOH-HCl. **III** and Me₂SO₄ give the *Me* ester, m. 165–6°, of 6-carboxy-3-keto-4-methyl-3,4-dihydro-1,4-benzoxazine, m. 287–90°.

In the reduction with Fe there is obtained an isomeric *Me ester* of IV, m. 151–4°, whose *Na salt*, m. 149–52° and effervesces 153–4°.

C. J. WEST

Transformation of benzoylacetic ester by concentrated and fuming sulfuric acid. FRANZ FEIST (with H. PAUSCHARDT AND H. DIBBERN). *Ber.* 58B, 2311–7(1925); cf. *C. A.* 18, 1818.—BzCH₂CO₂Et (I) allowed to stand a long time at room temp. with an equal wt. of concd. H₂SO₄ gives a cryst. compd. which was supposed to be α,α' -diphenylpyrone but which has been shown by Arndt (see following abstr.) to be the isomeric 4,6-diphenylcumalin (II). On the other hand, with fuming H₂SO₄ I gives chiefly an *Et anhydrobenzoylacetic acid* (III or IV). II, yellowish white, m. 138.5–9.0°, insol. in Na₂CO₃, sol. in alkalis only slowly on boiling, dissolves in H₂SO₄ without color and with faint blue fluorescence, gives no color with FeCl₃, reduces KMnO₄. Together with II are formed some BzOEt and PhCOMe. III or IV, from I added dropwise with stirring to 2.5 parts ice-cold fuming H₂SO₄ (70% SO₃) and stirred 30–60 min. longer (yield of crude product, 10% of the I), m. 140°, mol. wt. in camphor 230, forms an acid aq. soln., gives a red color with FeCl₃ in alc., dissolves in alkalis, reduces KMnO₄; its neutral Na salt gives ppts. with Pb(OAc)₂, SnCl₂, HgNO₃, HgCl₂, Cu(OAc)₂ (greenish white), FeCl₃ (red), FeSO₄ (orange-red), Co(NO₃)₂ (pink); no ppts. with Ba, Mg, Ag and Cr salts; in CHCl₃ suspension with Br it forms a *Br deriv.*, C₁₁H₈O₂BrS, m. 98.5°, sol. in Na₂CO₃ and alkalis, gives no color with FeCl₃. With O₃ in CHCl₃ III (or IV) gives (CO₂H)₂ and *o*-HO₃SC₆H₄CO₂H, while with 10 mols. boiling 20% NaOH it gives *benzoylacetic sulfonic acid*, m. 158–60°, whose *Me Et ester*, m. 104°, can be obtained directly from III (or IV) in MeOH and concd. H₂SO₄ on the H₂O bath. The chloride of III (or IV), prepd. by gently warming the acid with 1 mol. PCl₅, gives with excess of NH₄OH a yellowish white compd., m. 246–50°, free from N, and what is probably the *amide* (V or VI), m. 315°, sol. in Na₂CO₃ only on boiling (evolution of CO₂). On the other hand, with only a little more than 1 mol. NH₄OH the chloride gives, together with a N-free S compd., m. 136–7° (identical with a by-product (VII) obtained in the prepn. of III or IV), a *compd.* (probably VIII), faintly pink, m. 233–4°, mol. wt. in camphor 259.7, forms no Bz deriv. in faintly alk. soln. with BzCl, evolves an intense carbonylamine odor on heating in CHCl₃ with KOH and a violent isonitrile odor when heated in alc. with CS₂, and, after removal of the CS₂, with HgCl₂; with HNO₂ it regenerates III (or IV) and with KMnO₄ it uses up 3 atoms O and yields HO₃SC₆H₄CO₂H, (CO₂H)₂ and NH₃. VII is formed especially if the sulfonation of the I is too intense; it gives no color with FeCl₃ and is very probably an *acetophenone-o-sulfonic anhydride*, C₆H₄.CO.CH₂.SO₂.

C. A. R.

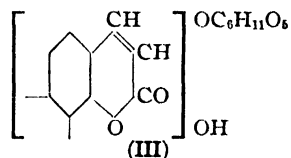

4,6-Diphenylcumalin. F. ARNDT AND B. FEISTERT. *Ber.* 58B, 2318–20(1925); cf. preceding abstr.—4,6-Diphenylcumalin (I) (4–5 g. from 20 g. BzCH₂CO₂Et allowed to stand 2–4 weeks in 20 g. concd. H₂SO₄), faintly yellowish, m. 138–8.5°, sol. in concd. H₂SO₄ with yellow color and blue fluorescence. 2-Thio *deriv.*, prepd. like 4-thiodiphenylpyrone (*C. A.* 19, 519), orange-red, m. 121–2°, unchanged by heating at 180° or by treatment with NH₄OH. I in CHCl₃ with 4 or more atoms Br or the 3-Br *deriv.* (II) below in C₆H₅ with Br give stout orange crystals (probably a 5,6-Br₂ addn. product of II) which at once lose Br in the air, becoming dark red and then orange again; they turn dark red at 40–50°, yellow at 80–90° and m. around 126°. II, from the above product in contact with alc. or allowed to stand *in vacuo* over alkalis, faintly greenish yellow, m. 130°, converted by hot aq. alc. NaOH into 2,4-diphenylfuran, m. 110°.

C. A. R.

β -Amyrin from Manila elemi resin. III. A. ROLLETT AND A. SCHMIDT. *Monatsh.* 45, 519–23(1925); cf. *C. A.* 17, 2117.—Oxidation of mixed amyryns with persulfate yields oxy- α - and - β -amyrin acetates as mixed crystals, m. 215–6°, from which neither isomeride can be sepd. When the mixed benzoates are oxidized with CrO₃ in AcOH, oxy- α -amyrin benzoate, m. 263°, can be isolated from the product first pptd. by the addn. of water, but the β -isomeride could not be isolated from subsequent ppts. Treatment of the mixed amyryns with Br in AcOH afforded bromoamyrin acetates as mixed

crystals, m. 215–6°. When a larger proportion of Br was applied, bromo- α -amyrin acetate, m. 263°, could be isolated, but the more sol. β -isomeride could not be crystd. Bromination of the mixed acetates gave similar results. B. C. A.

Constitution and synthesis of daphnin. P. LEONE. *Gazz. chim. ital.* 55, 673–8 (1925).—A glucoside, daphnin (I), is extd. from *Daphne alpina* and *Daphne mezereum*. Stunkel (*Ber.* 12, 110) found that I, m. 200° (decompn.), gives glucose and dihydroxycoumarin, called daphnetin (II). The constitution assigned to (I) was (III) in which the

substituents in positions 3 and 4 remain undetd. Several glucosides have been prepd. from hydroxycoumarin, e. g., Glaser and Kraus (*C. A.* 18, 76) prepd. esculin and Mauthner (*C. A.* 9, 1908) prepd. skimmmin. L. prepd. II from pyrogallaldehyde (IV) and Ac_2O (+NaOAc) by the method of Gattermann and Köbner (*Ber.* 32, 487). IV was prepd. by the modified method of Adams and Levine (*C. A.* 17, 3867). β -Acetobromoglucose (V) was prepd.

from anhyd. glucose and AcBr . 1.5 g. II in 3.5 cc. 10% NaOH was treated slowly with cooling with 3.5 g. V in 20 cc. Me_2CO . After standing 12 hrs. the Me_2CO was evapd. *in vacuo*. The sirup was beaten up with H_2O and crystd. from MeOH. The tetra-cetylglucodaphnetin (VI) obtained, m. 220°, $[\alpha]_D^{17}$ –52.52°. 1.5 g. in 150 cc. MeOH was cooled with ice and satd. with NH_3 . The liquid was evapd. *in vacuo* over H_2SO_4 until all NH_3 was lost. A few drops of AcOH was then added and most of the EtOH was allowed to evap. I sepd. as a powder, m. 215–6°, $[\alpha]_D^{17}$ 29.4°, identical with I from natural sources. It was not detd. which of the 2 possible formulas (cf. III) is correct.

E. J. WITZEMANN

Action of phosphoric acid on certain terpenes and related compounds. P. G. CARTER, H. G. SMITH AND JOHN READ. *J. Soc. Chem. Ind.* 44, 543–7T (1925).—The action of H_3PO_4 on certain terpenes (and cineole) results, through isomerization, polymerization, etc., in the formation of a mixt. of other terpenes (chiefly α -terpinene) and a diterpene (I), $\text{C}_{20}\text{H}_{32}$, both of which resist strongly the further action of H_3PO_4 at ordinary temp. The diterpenes from various sources show close agreement in phys. properties (except optical activity); the values of $[\text{R}_L]_D$ point to a dicyclic diterpene with 3 ethylene linkings. The purest prepn. b_{24} 193–5°, b_{788} 315–9°, d_4^{20} 0.9240, n_D^{20} 1.5175; from 13° to 30°, $\delta n_D/\delta t$ = –0.00042; $\delta d/\delta t$ = –0.00081; the highest optical activity was observed in a fraction from the phellandrene fraction of the oil of *Eucalyptus dives*, α_D^{20} 21.2°. I decolorizes Br- H_2O or Br in CHCl_3 , HBr being evolved in the latter instance; no cryst. deriv. could be obtained from this, or from HCl, HNO_3 , NOCl, etc. I appears to be very susceptible to oxidation (KMnO_4). *l*- α -Phellandrene gave approx. 40% of crude I, α_D^{20} 14.96°; that from *E. dives* oil, 50% with α_D^{20} 13.20°; from *E. phellandria* oil, 40%, 3.28°; from *Melaleuca acuminata* oil, 45%, 1.00°; *d*-limonene, 75%, 0.16°; *d*-pinene, 75%, –0.10°; *l*-pinene, 75%, 0.07°; cineole, 60%, 0.00°. Other phys. properties of these products are reported. C. J. WEST

The terpene and sesquiterpene of Mitsuba-zeri. Preliminary report. NENOKICHI HIRANO. *J. Soc. Chem. Ind. Japan*, 29, 48–52 (1926).—By steam distn. of Mitsuba-zeri (*Cryptolaenia japonica* Hassk. (*Umbellifer*), a terpene cryptotenene, $\text{C}_{10}\text{H}_{16}$, and a sesquiterpene mitsubene, $\text{C}_{15}\text{H}_{24}$, have been isolated. Cryptotenene: b_{18} 67–8°, $[\alpha]_D^{19.8}$ 2.66°, d_4^{25} 0.8128, n_D^{25} 1.47476, forms a triozonide but only 4 atoms of Br are added, which shows the presence of a conjugated double bond. By the decompn. of the triozonide, CO_2 , HCO_2H , Me_2CO , acetone superoxide, succinic acid and a C:O compd. were isolated and as an α -ketonic acid is generally oxidized into a mono- CO_2H acid, the formula of cryptotenene will therefore be: $\text{Me}_2\text{C}:\text{CHCH}_2\text{CH}_2\text{CH}:\text{CH}:\text{CH}:\text{CH}_2$ or $\text{Me}_2\text{C}:\text{CHCH}:\text{CHCH}_2\text{CH}_2\text{CH}:\text{CH}_2$. Mitsubene, b_{18} 142–3°, $[\alpha]_D^{21.9}$ 8.31°, d_4^{25} 0.9175, n_D^{25} 1.50381, and its Br addn. compd. contains 4 atoms of Br. On heating mitsubene with S and treating the product with picric acid, a picrate is obtained, whose m. p. (90°) is identical with that of eudalene picrate (Ruzicka, *C. A.* 15, 3476; 16, 2501). Mitsubene is therefore a sesquiterpene of the eudesmol type. CO_2 and HCO_2H were isolated from the ozonide by decompn. The study is going on. K. K.

• **The isonitriles.** XIII. Reaction of phenyl isonitrile with pernitrosomenthone. MARIO PASSERINI. *Gazz. chim. ital.* 55, 721–6 (1925); cf. *C. A.* 20, 593.—In a previous paper (*C. A.* 19, 264) the action of PhNC on pernitrosocamphor was described. In this paper the action of PhNC on pernitrosomenthone (I) is given. To 5 g. I in a little Et_2O were added 2.7 g. PhNC . After 8–10 days the cryst. mass of α -mentholcarboxylic

δ-anilide (II), $\text{Me}_2\text{CHCH}(\text{CH}_2\text{CH}_2\text{CHMeCH}_2\text{C}(\text{OH})\text{CONHPh})$, colorless, m.

166–8°, $[\alpha]_D^{10}$ 62.62, was filtered off. A compd. isomeric with II, m. 134–6°, was obtained in small quantity. II is quite resistant to hydrolyzing agents. Only by heating 80 hrs. at 120–30° in a sealed tube with concd. EtOH-KOH is it saponified, in part, giving PhNH_2 and α -mentholcarboxylic acid, m. 112–3°. 3 g. II with 12 cc. concd. $\text{H}_2\text{SO}_4 + 9$ g. $\text{K}_2\text{Cr}_2\text{O}_7$ was heated on the H_2O bath for 0.5 hr. and then steam-distd. The oily portion of the distillate was taken up in Et_2O and identified as *l*-menthone by converting it into the oxime, m. 58°, and the semicarbazone, m. 184°. E. J. WITZEMANN

The blue oil of peat tar. J. HERZENBERG AND S. RUHEMANN. *Ber.* 58B, 2249–62 (1925); cf. R. and Benthin, *C. A.* 19, 1190.—The opinion was expressed in the earlier paper that the blue color and fluorescence of the neutral oil from peat retort tar was due to a substance related to that present in the high boiling dark blue oil obtained from camomile and many other ethereal oils, which can also be prepd. from certain sesquiterpenes (e. g., α -gurjunene) and from which Sherndal isolated a dark blue hydrocarbon, azulene, $\text{C}_{18}\text{H}_{18}$ (I) (*C. A.* 9, 2089). The present work was undertaken to study the nature of the blue oil from peat and to clear up its formation from the bitumen of the peat in the retort carbonization. The fractions described in the earlier paper were shaken with aq. $\text{H}_4\text{Fe}(\text{CN})_6$ and the ferrocyanides again decompd. with dil. NaOH . In this way from the neutral oil fractions b_{14} 130–75° were isolated small amts. of deep blue, strongly fluorescent oils. The limits of the b. ps. of these “blue oils” were further apart than those of the original fractions, however, indicating that they were mixts. contg. varying amts. of the pure blue oil. Moreover, the parts of the neutral oil volatile with steam at 100° contained the blue oil in about the same amts. as the parts not volatile with steam at 100°, investigated by Benthin. The yield of ferrocyanides and of blue oils increases with increase in the b. p. of the various fractions up to that b_{14} 175°; in the fractions boiling above this temp. the oils isolated by means of $\text{H}_4\text{Fe}(\text{CN})_6$ are no longer blue. The yield in blue oils also varies considerably with tars taken at different times from the same retort. Among their properties are to be noted the intense blue color of their vapors and their sensitiveness to oxidizing and reducing agents; on long standing in the air the blue color changes to brown and it is also destroyed by weak oxidizing agents ($\text{Hg}(\text{OAc})_2$) and by reducing substances (SO_2). On the other hand, the blue oils are not affected by rise in temp. and can be distd. under atm. pressure almost without decompn. The compn. of the various blue fractions and especially the wide range within which they boil indicates that they are complex mixts. and in view of the small amts. available chem. sepn. seemed hopeless and attempts at identification by an exact spectrophotometric study of them seemed to offer the greatest chance of success. A blue oil was accordingly prepd. from gurjunene by Sherndal's method, and the visible spectra of alc. solns. of it and of the blue oil from peat were photographed and the intensity of the absorption at the different wave lengths was measured with a registering microphotometer. The results leave no doubt that the blue color of the oils from both sources is due to the same constituent. Moreover, by catalytic dehydrogenation of gurjunene at 400°, using as catalyst finely divided Ni deposited on Al_2O_3 (prepd. by pptg. an equimol. soln. of Ni and Al nitrates (about 1%) with NH_4OH), it is possible to obtain up to 4–5% pure I (as compared with 0.4% by the Sherndal method), which can be isolated either by converting the crude product into the colorless ferrocyanide and thence into the blue-black picrate or by fractionating it and sepg. it directly as the picrate, m. 116–7° (the slightly higher m. p. (122°) reported by S. is probably due to the fact that the picrate is so unstable that it can hardly be said to have a sharp m. p.). H. and R. believe that the formation of I from gurjunene involves not only a dehydrogenation but also probably a condensation with formation of a new ring; at any rate, as will be shown in later papers, I is not a pentamethylbenzofulvene, as suggested by Kremers (*C. A.* 17, 1459). It is likely that the I does not exist preformed in peat (the characteristic blue color and fluorescence has never been observed in exts. of peat) but is probably formed during the process of carbonization from the resin constituents of the bitumen, which by pyrogenic decompn. are partially broken down into sesquiterpenes from which the I is formed during the carbonization. The neutral oil of peat tar should therefore contain such sesquiterpenes, for it is not probable that they would be completely converted into I during the carbonization. A fraction of peat neutral oil, b_{16} 120–50°, was accordingly distd. repeatedly *in vacuo* over Na, yielding light yellow, almost colorless oils; of these, the fraction b_{12} 126–33°, when dehydrogenated over Ni at 340–50°, yielded a product with the pure blue color of I; the fractions b_{12} above 133° gave products with only a green mixed color. In the carbonization process the only dehydrogenating catalysts which can come into play are the coke or

finely divided C and the ashes contg. Fe oxide; that C can play such a role is shown by the fact that gurgunene passed over active "T-Kohle" at 410–20° splits off H vigorously and yields a product with the characteristic blue color of I. There are numerous reports in the literature of the formation of blue oils from bicyclic sesquiterpenes, such as cadinene, and even from terpenes by the action of concd. H_2SO_4 and Ac_2O , but H. and R. have shown that such results are in every case due to the presence of I-forming sesquiterpenes. Thus, a well-fractionated *d*-sylvestrene, d_{14} 0.8577, n_D^{21} 1.4789, after repeated distn. over Na *in vacuo* gave on catalytic dehydrogenation a colorless product almost completely sol. in H_2SO_4 contg. 7% SO_3 , whose const. (d_{14} 0.861, n_D^{23} 1.4918) agree with those of *m*-cymene; similar results were obtained with cadinene and caryophyllene. C. A. R.

The pseudo acids. G. B. SEMERT AND A. PICHIETTO. *Gazz. chim. ital.* **55**, 679–87 (1925).—In spite of the large literature on the pseudo acids no one has compared the properties of 2 structurally isomeric pseudo acids. S. and P. have now compared 2 pseudo acids, $\text{C}_{10}\text{H}_{16}\text{O}_3\text{N}$: nitrocamphor (I) and camphoryl oxime (II) and their resp. Na salts. I and its Na salt were prepd. according to Lowry (*J. Chem. Soc.* **73**, 995 (1898)). II and its Na salt were prepd. by a modification of L.'s method. The variations of the cond. with the temp. of solns. of I and II and their Na salts demonstrate the pseudo acid character of I and II. For the temps. 25°, 30° and 35° the cond. of the Na salt of II increases more rapidly with diln. than does the Na salt of I; for the temps. 40°, 45° and 50° the reverse is true. It follows that the degree of ionization of the salt of I is greater than that of the salt of II for the 1st temp. and less for the last. Likewise the slow neutralization confirms the pseudo acid character of the 2 compds.; on that account in the case of I equil. is reached in a shorter time, which agrees with the fact that below 35° the Na salt of I has a greater degree of ionization than that of the salt of II. The refractometric data on the Na salts of I and II lead to values very near those of the mol. refraction; the small differences are attributed to the different structure. The rule of Muller was verified for II: in fact the difference between M_{salt} and M_{acid} is 1.7, *i. e.*, greater than the difference found for the weak acids. When this difference is subtracted from the mol. refraction of the Na salt of I the value 61.28 is obtained for the mol. refraction of I, which is considered to be nearly correct. Also *Atti accad. sci. Torino* **60**, 599 (1925). E. J. WITZEMANN

Isomeric thujones (tanacetones). *d*- α -Thujone. V. PAOLINI. *Ann. chim. applicata* **15**, 414–6 (1925).—The existence of an α -thujone with $[\alpha]_D$ 10.23° has already been shown by P. (C. A. **6**, 2233). Furthermore since the *l*- α -thujone prepd. by Wallach (cf. *Ann.* **336**, 263 (1904)) is very unstable in respect to its rotatory power without any accompanying change in its other const., it was considered probable that this latter thujone changed to the former by stereoisomerization. Expts. now confirm this assumption. Steam distn. of a mixt. of the semicarbazone and $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ yields only *l*- α -thujone with $[\alpha]_D$ –10.23°, but if the mixt. is heated with H_2O at 100° as in ordinary hydrolyses, a *d*- α -thujone with $[\alpha]_D$ 10.23° is obtained. The *l*- and *d*- α -thujones gave an optically inactive mixt. The prolonged action of H-ions therefore causes inversion of the stereoisomeric form of α -thujone, the ionic concn influencing both the velocity of this inversion and the final equil. between the 2 forms. The latter explains why Wallach obtained a product with $[\alpha]_D$ –5°13' and why P. by working under the limiting conditions obtained 2 pure stereoisomeric forms. C. C. DAVIS

Chemistry of the caryophyllene series. I. G. G. HENDERSON, J. M. ROBERTSON AND C. A. KERR. *J. Chem. Soc.* **1926**, 62–70.—Caryophyllene (I) (150 g.), heated with 1 l. AcOH contg. 12 cc. H_2SO_4 and 40 cc. H_2O at 80–100° for 30 hrs., gives about 30% of caryophyllene alc. (II) and an unsatd. compd., $\text{C}_{15}\text{H}_{24}$, b_D 110–4°, n_D^{10} 1.5010, d_4^{10} 0.9263, α_{5790}^{16} –19.56°; this may be the same as the tricyclic caryophyllene obtained from the di-HCl salt by the quinoline method, and possibly with clovene. II is unchanged after heating with H_2O_2 in glacial AcOH at 50–5° for 52 hrs.; it is not attacked by cold 1% KMnO_4 or by Br in CHCl_3 at room temp. This would indicate that II cannot be regarded as a direct hydrate of I but that some ring closure has taken place with the formation of a new tricyclic structure. II formate, d_4^{17} 1.024, n_D^{17} 1.4998, $[R_L]_D$ 71.02; II acetate, d_4^{17} 1.003, n_D^{17} 1.4919, $[R_L]_D$ 75.64; these values clearly indicate the tricyclic nature of the I radical. I in Et_2O and dry HCl give the di-HCl salt, m. 69°, $[\alpha]_D^{67}$ 67° (EtOH, 2.5%); in glacial AcOH with AcOAg, there results some regenerated I; about 20% of an unsatd. alc., caryophyllol, $\text{C}_{15}\text{H}_{24}\text{O}$, b_{10} 142–50°, d_4^{17} 1.5015, $[R_L]_D$ 68.03 (calcd. for dicyclic alc., 68.12), unsatd. towards Br and alk. KMnO_4 and gives an oily dibromide, slowly decomp. in the light; and about 3% of a glycol, $\text{C}_{11}\text{H}_{22}\text{O}_2$,

m. 173°, satd. towards Br and alk. KMnO_4 . II and PCl_5 give *chlorodihydrocaryophyllene*, m. 63°; it is recovered unchanged after boiling with concd. EtONa for 12 hrs., with quinoline at 210° for 3 hrs. but with AcONa in AcOH it yields the acetate, b_{10} 149–52° m. 40°. HOCl and I give a yellow oil *dichlorohydrin* (?), $\text{C}_{15}\text{H}_{24}(\text{OH})_2\text{Cl}_2$, is not volatile with steam and does not distil without decompn.; Ac_2O gives a *monoacetate*, b. 190–200°; distn. at 1 mm. gives an *anhydride*, $\text{C}_{15}\text{H}_{24}\text{OCl}_2$, b. 125–40°, satd. towards Br and KMnO_4 . Attempts to remove the Cl failed, Na-Hg giving a product with 1 Cl, b_1 120–30°. Oxidation with H_2O_2 gave only succinic acid. C. J. WEST

Oxidation of certain sesquiterpenes with chromyl chloride and chromic acid. D. T. GIBSON, J. M. ROBERTSON AND JAMES SWORD. *J. Chem. Soc.* 1926, 161–7.— β -Caryophyllene, b_9 119°, n_D^{18} 1.5030, $[\alpha]_D^{15}$ —5.2°, gives with CrO_2Cl_2 the *addn. product* $\text{C}_{15}\text{H}_{24} \cdot 2.5\text{CrO}_2\text{Cl}_2$, even when different proportions of the CrO_2Cl_2 are used. Decompn. with H_2O yields a *ketone*, $\text{C}_{15}\text{H}_{24}\text{O}$, b_1 100–10°, and giving a *semicarbazone*, m. 234°; an unsatd. *ketone*, $\text{C}_{15}\text{H}_{20}\text{O}$, b_1 118°, caryophyllene alc., and some chlorinated oxidation products, but no aldehyde. Cedrene, b_8 123–5°, d_4^{20} 0.9361, n_D^{17} 1.5017, $[\alpha]_D^{17}$ —55.4°, gave a similar *addn. product*, which, on decompn. with H_2O , yields a *ketone*, $\text{C}_{15}\text{H}_{24}\text{O}$, $b_{0.15}$ 93°, n_D^{18} 1.5462, mol. wt. in freezing C_6H_6 , normal; *semicarbazone*; and chlorinated oxidation products. Cadinene, b_{10} 130–4°, d_4^{20} 0.9189, n_D^{20} 1.5097, $[\alpha]_{5461}^{18}$ —125°, gives a similar *addn. product*, which, on decompn., yields a small amt. of a non-cryst. acid and about 10% of a neutral product which does not give a cryst. semicarbazide. Oxidation of cadiene with CrO_3 in glacial AcOH gives the *compd.* $\text{C}_{15}\text{H}_{24}\text{O}_2$, b_{12} 180–96°, n_D^{20} 1.5095, which is unsatd. towards Br and alk. KMnO_4 , appears not to contain a CO or OH group and is polymerized by Na. The acid portion contd. 59.2% C and 8.4% H; its Ag salt contd. 35.4% Ag. C. J. WEST

Behavior of mixed *O*-acyl-*N*-acyl derivatives in which the reacting groups are not on adjacent carbon atoms. L. C. RAIFORD AND E. P. CLARK. *J. Am. Chem. Soc.* 48, 183–9(1926).—2-Benzoyloxy-3,5-dibromobenzylacetanilide, m. 150°, shows no tendency to rearrange and on hydrolysis gives the original material. *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{CH}_2\text{OH}$ gives an *Ac acetate*, m. 95°; hydrolysis yields the *alcohol*, m. 116°, whose *benzoate* m. 110°. The *Bz benzoate*, m. 131–2°, the free *alcohol* 95° and the *acetate* 115°; mixed m. p. of the *Ac benzoate* and *Bz acetate*, 80–105°. 4'-Benzoylamino-4-benzoyloxydiphenyl, m. 273–4°; the 4-hydroxy *compd.* m. 284° and the 4-acetyloxy *compd.* m. 227°. 4'-Acetylamino-4-acetyloxydiphenyl, m. 219–20°; the 4-hydroxy *compd.*, m. 224–5° and the 4-benzoyloxy *compd.*, m. 254–5°. This behavior opposes the theory that positions 4 and 4' of Ph_2 derivs. are fixed relatively as suggested by the Kauler-Cain formula. 8-Benzoylamino-1-benzoyloxynaphthalene, m. 207–8°; hydrolysis gives the 1-hydroxy *deriv.*, m. 216°, whose *acetate* m. 180°. 8-Acetylamino-1-acetoxynaphthalene m. 118° and the 1-hydroxy *deriv.* m. 181°; its *benzoate* is identical with the above *acetate*, m. 180°, indicating that a mol. rearrangement occurred in 1 case and that positions 1 and 8 have a relationship approaching that of an *o*-compd. C. J. WEST

"Fluorenone hydrate." RICHARD KUHN AND ALBERT WASSERMANN. *Ber.* 58B, 2230–1(1925).—Schmidt and Mezger by boiling α -9-acetoxyluorene (I) with concd. HCl obtained a *compd.* (II), m. 94°, which they believed to be 9,9'-dihydroxyfluorene (*Ber.* 39, 3895(1906)). Repetition of their work yielded a substance (III), m. 91.5°, similar to II in soly., color reaction with H_2SO_4 and volatility with steam, unchanged by $\text{NH}_4\text{OH.HCl}$ in the presence of BaCO_3 and giving fluorene, m. 114°, with Na-Hg in alc. That boiling Ac_2O converts it into fluorenone, as stated by S. and M., is incorrect; only unchanged III can be isolated from the product. 9-Chlorofluorene, identical with III (and II) can be obtained by boiling fluorene alc. 15 min. in concd. HCl . The I, m. 69.5°, is best prepd. by heating *ms*-fluorene alc. in $\text{C}_6\text{H}_5\text{N-AcOH}$ 0.5 hr. on the H_2O bath. C. A. R.

Stereochemistry of aromatic compounds; the isomerism of the 9-aminofluorenes (addendum). RICHARD KUHN AND PAUL JACOB. *Ber.* 58B, 2232(1925).—Since the publication of the original paper (*C. A.* 20, 48) the *compd.* m. 161° first described by Kerp has become readily available by a method of prepn. devised by Bader and has been found to be not a H_2CO_3 deriv. but an *acetate* of γ -9-aminofluorene; the unstable free *base* m. 46–6.5°, the m. p. rising rapidly when the *base* is kept in a desiccator. Cf. also Wieland and Krause, *C. A.* 19, 2334. C. A. R.

Nickel carbonyl carbon monoxide and Grignard reagents. WM. L. GILLILAND AND A. A. BLANCHARD. *J. Am. Chem. Soc.* 48, 410–20(1926).—CO has been made reactive with Grignard reagents but only as a constituent of $\text{Ni}(\text{CO})_4$, the $\text{Ni}(\text{CO})_4$ is, however, continuously regenerated from the liberated Ni and fresh CO. With PhMgBr the identified products are Ph_3CH , $\text{Ph}_2\text{C:CPhOH}$, $\text{Ph}_3\text{CCHPh}_2$ and $\text{Ph}_3\text{C:}$ —

CPh_2 . Reactions for the formation of these compds. are formulated on the assumption of a structure $\text{Ni}(\text{:C:O})_4$, the double bond Ni:C being the first point of attack, both the MgBr and Ph groups adding to the C atom. The C:O double bond may still be attacked in the normal way and the new C-MgBr grouping is capable of reacting as a new Grignard reagent, thus giving a great no. of possible substances, a mixt. of which is probably contained in the non-cryst. oil that comprises rather more than 0.5 of the entire product. C. J. WEST

Conception of the "polymethine dyes" and a general dye formula derived therefrom as the basis of a new system of dye chemistry. W. KÖNIG. *J. prakt. Chem.* 112, 1-36 (1926).—General theoretical discussion of the formulation of dyestuffs. C. J. WEST

Action of pyridine solutions of benzoin and of aromatic aldehydes on metallic copper. H. MOHLER. *Helvetica Chim. Acta* 8, 740-57 (1925).—The soln. of Cu by BzCH(OH)Ph (I) in $\text{C}_6\text{H}_5\text{N}$ (Bernoulli, private communication) is caused by BzOH resulting from the oxidation of I, the resulting blue compd. being Cu(OBz)_2 with $\text{C}_6\text{H}_5\text{N}$ of crystn. (II). The reaction rate (r. r.), detd. by the amt. of Cu in soln., was const. in the beginning, and then increased. O_2 increases the r. r., is necessary for the soln. of the Cu , and is used up in the reaction. Old solns. of I react more rapidly than fresh ones, but this is due not only to the formation of Bz_2 , but to free O_2 as well, which, in the presence of Cu , can carry the oxidation still further. If BzOH or $\text{Ph}_2\text{C(OH)CO}_2\text{H}$ is substituted for I the r. r. is greater and if the reaction is run in the absence of air, reduction of the acid takes place. $\text{Cu-C}_6\text{H}_5\text{N-O}_2$ is a system of strong oxidizing power, in which other solvents, such as C_7H_8 , $\text{C}_6\text{H}_7\text{N}$ and $\text{C}_6\text{H}_{11}\text{NH}$, are less effective. Oxidation of the I to BzOH by O_2 depends on the Cu , while the resulting acid can only react with Cu in the presence of O_2 or reducible substances. The r. r. depends on the Cu surface exposed, and is accelerated by the addn. of II. The phenomena are best explained on the basis of a heterogeneous coupled reaction with at least two induction periods I. $\text{BzCH(OH)Ph} + \text{O}_2 + (\text{Cu}) \rightarrow \text{BzOH}$. II. $\text{BzOH} + \text{Cu} + (\text{O}_2) \rightarrow \text{Cu(OBz)}_2$. Substitution of BzH , PhCH:CHCHO , $p\text{-MeC}_6\text{H}_4\text{CHO}$, $p\text{-MeOC}_6\text{H}_4\text{CHO}$, $p\text{-Me}_2\text{NC}_6\text{H}_4\text{CHO}$ and $p\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ for I showed the r. r. in these cases to depend both on the ease of oxidation of the aldehyde and on the reactivity of the resulting acid with Cu . Numerous tables of exptl. detd. values of dissolved Cu are given to substantiate the statements made, and the results are expressed in a series of curves. M. HEIDELBERGER

Preparation of 1-halogeno-2-nitronaphthalenes and 2-nitronaphthalene. H. H. HODGSON AND ERNEST KILNER. *J. Chem. Soc.* 129, 7-10 (1926).— $2\text{-O}_2\text{NC}_{10}\text{H}_6\text{NH}_2$ (I) is readily obtained from $2\text{-O}_2\text{NC}_{10}\text{H}_6\text{OH}$ by heating with concd. NH_4OH and $(\text{NH}_4)_2\text{CO}_3$ at $120\text{-}30^\circ$ for 6 hrs. The 4- NO_2 deriv. is best prepd. at $140\text{-}60^\circ$. Hydrolysis of aceto-1-nitro-2-naphthalide is best effected by acid, giving $1,2\text{-O}_2\text{NC}_{10}\text{H}_6\text{NH}_2$. Very slow decompn. of diazotized I by CuCl in HCl gives 1-chloro-2-nitronaphthalene, pale yellow, m. 76° (2.5 g. from 5 g. I); the 1-bromo deriv., bright yellow, m. 97° , results in 0.95 g. yield; the 1-iodo deriv., pale yellow, m. 111° , in 1.9 g. yield. I (4.2 g.) gives 1.24 g. 2-nitronaphthalene, yellow, m. 79° ; cinnamon-like odor. C. J. WEST

Action of sulfurous acid upon aromatic amino and hydroxyl compounds. XII. Products of the action of sulfites on 1,8-dinitronaphthalene. H. TH. BUCHERER AND HANS BARSCH. *J. prakt. Chem.* 111, 313-39 (1925); cf. C. A. 20, 195.—A study of the reaction of NaHSO_3 on $1,8\text{-C}_{10}\text{H}_6(\text{NO}_2)_2$ according to D. R. P. 79,577 (A. Fischesser and Co.) shows that the formation of the 1,8,2,4,5-naphthylenediaminetrisulfonic acid does not proceed as smoothly as the patent would indicate; during the reaction there are formed H_2SO_3 esters of the 1,8-aminonaphtholtrisulfonic acid, which decreases the yield. The yellow-brown reaction product, on making alk. in the cold, becomes green; addn. of acid changes the color to violet. According to the Höch patent (D. R. P. 215,338), in which NaHSO_3 reacts in the presence of NH_3 , the yield of 1,4,7-naphthylaminedisulfonic acid (I) (13.2%) is also decreased by the formation of SO_2 esters of 1,8-aminonaphtholdisulfonic acid (II). It is possible by coupling reactions under suitable conditions to prove the presence of I, II and 1,8-naphthylenediaminedisulfonic acid. The sulfonation of $1,8\text{-C}_{10}\text{H}_6(\text{NH}_2)_2$ gives 1,8,4-naphthylenediaminesulfonic acid and a di- SO_3H acid; these resemble closely the Fischesser acid in their color reactions but differ considerably in their capacity to form disazo dyestuffs. C. J. WEST

Fluorescent derivatives of β -naphthol. A. SAKOSCHANASKY. *Chem. News* 131, 39 (1925).—The compd., $\text{NMe}_2\text{C}_6\text{H}_4\text{CH(OH)CCl}_3$, formed by the action of chloral hydrate on PhNMe_2 , reacts with β -naphthol at 200° , giving a substance which shows strong reddish green fluorescence in concd. H_2SO_4 . Chloral hydrate reacts with β -naphthol at high temps., giving a non-fluorescent substance. B. C. A.

Nitration of β -naphthoic acid and some new amino- and nitronaphthoic acids.

H. A. HARRISON AND F. A. ROYLE. *J. Chem. Soc.* 1926, 84–9.—Repetition of Ekstrand's expts. on the nitration of β - $C_{10}H_7CO_2H$ in the absence of solvent shows that approx. equal amts. of the 5- and 8- NO_2 derivs. are formed in at least 95% combined yield, together with a trace of the 1- NO_2 deriv. $HOC_{10}H_6CO_2Na$, heated with NH_4OH and a satd. soln. of SO_2 at 15° in an autoclave at 200 – 10° for 10 hrs., gives an almost quant. yield of the amino acid. 6-Amino-1-naphthoic acid, light brown, m. 203° ; HCl salt, needles; Ac deriv., m. 170 – 2° . The 7-amino deriv., light brown, m. 223 – 4° 1; HCl salt, needles; Ac deriv., m. 229 – 30° . 6-Amino-2-naphthoic acid, pale yellow, m. 225° ; HCl salt, small flakes; Ac deriv., m. 230 – 2° . The 7-amino deriv., pale yellow, m. 245° ; Ac deriv., m. 200 – 1° (decompn.); the fluorescence exhibited in various solvents is tabulated. The NH_2 acid is converted into the NO_2 acid by treating the diazo soln. with Cu powder and excess of $NaNO_2$. 6-Nitro-2-naphthoic acid, pale yellow, m. 310° ; Et ester, m. 177° , brownish yellow. 7- NO_2 acid, yellow, m. 262° ; Et ester, m. 131° , pale salmon. C. J. WEST

Action of diamines on naphthalic anhydride. A. BISTRZYCKI AND J. RISI. *Helvetica Chim. Acta* 8, 810–20(1925).—On 2 successive occasions 1,8- $C_{10}H_6(CO)_2O$ (I) suspended in boiling alc. and alc. $N_2H_4 \cdot H_2O$ gave 1,8-naphthalhydrazide, $C_{10}H_6(CONH)_2$ (II), leaflets or pale yellow needles, m. 25 – 5° (darkening), does not yield a benzal deriv. or combine with more I as $C_{10}H_6(CO)_2NNH_2$ (III) (Ostrogovich and Mihailescu, *C. A.* 6, 995) does; it m. 242° when mixed with III; di-Ac deriv., m. 214 – 5° . After several months further attempts to prep. II resulted only in the formation of III. I and $(CH_3NH_2)_2$, heated in boiling alc. only until crystals sep., give *N*-[8-carboxy-1-naphthoyl]-ethylenediamine (IV), $HO_2CC_{10}H_6CONHC_2H_4NH_2$, decomps. 196 – 7° , splits into its components in the higher boiling solvents, is partly sol. in dil. aq. $NaHCO_3$ or HCl, fluoresces more strongly in H_2SO_4 than does I; Pb salt, amorphous. At 230 – 40° for 10–15 min.

IV yields 1,2-[1',8'-naphthoylene]-imidazole 4,5-dihydrate $C_{10}H_6.CO.N.C_2H_4.CH_2.N.C$,

greenish yellow, m. 179 – 80° (decompn.), fluoresces in H_2SO_4 , stable to boiling alc. KOH. 8-Carboxy-1-naphthoyl-*o*-phenylenediamine (V), $HO_2CC_{10}H_6CONHC_6H_4NH_2$, yellow, gradually loses H_2O when heated, m. 236 – 8° (decompn.), partly sol. in dil. aq. $NaHCO_3$ or HCl, sol. in H_2SO_4 with an orange color; Ag salt, amorphous. Heated 10 min at 150° , then gradually to 230 – 40° , V forms 1,2-[1',8'-naphthoylene]benzimidazole,

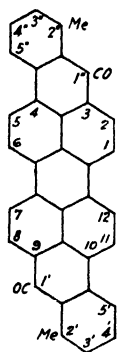

$C_{10}H_6.CO.N.C_6H_4.N.C$, greenish yellow, m. 189° sol. in H_2SO_4 with a greenish yellow

color. Unlike the corresponding benzoylene compd. (B. and Cybulski, *Ber.* 25, 1990 (1892)) it is not reduced by Zn dust in boiling HOAc. *N*-[1'-Amino-2'-naphthyl]-1,8-naphthalimide acid (VI), almost colorless, m. 143 – 4° when rapidly heated, sol. in H_2SO_4 with a brownish orange-red color; Ag salt, flocks; 1,2-[1',8'-naphthoylene]- α -naphthimidazole, from VI, heated 15 min. at 230 – 40° , brownish orange, m. 238 – 9° (decompn.). To decide whether condensation in VI had actually occurred on the 2- NH_2 group of 1,2- $C_{10}H_6(NH_2)_2$, (VII) $C_6H_4(CO)_2O$ and VII were heated in boiling alc. or PhH, giving *N*-[1'-amino-2'-naphthyl]phthalimide acid (VIII), decomps. ca. 205° (Ag salt, amorphous), converted by treatment with 12% HCl, drying on clay, and boiling under a reflux with $AmONO$ and a few drops of 12% HCl into *o*- $HO_2CC_6H_4CONHC_{10}H_7(\beta)$, dimorphic. At 270 – 80° for 15 min. VIII yields 1,2-[1',2'-benzoylene]- α -naphthimidazole, orange, m. 208° , sol. in H_2SO_4 with an orange color. M. HEIDELBERGER

Phenyl α -acenaphthyl ketone (5-benzoylacenaphthene) and phenyl- α -acenaphthylmethane (5-benzylacenaphthene). KAROL DZIEWONSKI AND MIECZYSLAW RYCHLIK. *Ber.* 58B, 2239–49(1925).—Ph α -acenaphthyl ketone (I), m. 100 – 1° , was obtained in 60–70% yield essentially by the method of Graebe and Haas (*Ann.* 327, 96(1903)); it is reduced in alc. at 50° with Zn dust and concd. aq. KOH or in boiling alc. with Na-Hg to the carbinol, m. 113 – 4° , easily sol. in concd. H_2SO_4 with violet-blue color changing to olive-green (sulfonation) on long standing. With Na in abs. alc. on the H_2O bath I gives α -benzoylacenaphthene (phenyl- α -acenaphthylmethane) (II), b₁₈ 210 – 5° , m. 110 – 1° , identical with the product obtained from $PhCH_2Cl$ and acenaphthene in the presence of $ZnCl_2$ and erroneously designated as a β - $PhCH_2$ deriv. (*Bull. acad. sci. Cracovie*, 1904, 36). 4-Benzoylnaphthalic anhydride (III), obtained from I or best from II in $AcOH$ with $Na_2Cr_2O_7$, is completely converted at 140 – 50° into its anhydride, m. 200 – 1° . Two different oximes of benzoylnaphthalic anhydride are described in the literature and the opinion had been expressed that they are derivs. of the structurally isomeric α - and β -Bz anhydrides but D. and R. now believe that they are *cis-trans* isomeric derivs. of III. The oxime m. 254 – 5° (decompn.), light yellow, strongly refracting rhombohedrons,

easily sol. in alkalis with light yellow color, is obtained by heating **III** in 1-2% NaOH with $\text{NH}_4\text{OH} \cdot \text{HCl}$ for several hrs. on the H_2O bath and when heated a few min. in AcOH contg. some Ac_2O it changes into the isomer m. 199-200°, snow-white needles easily sol. in alkalis and converted back by long heating in 60% soln. (solvent not stated.—ABSTR.) into the form m. 254-5°. 4-Benzyl-naphthalic anhydride, m. 170-1°, previously obtained by gentle oxidation of **II** and supposed to be a β - PhCH_2 deriv., has now been prepd. by reducing **III** in NaOH with Zn dust and $\text{NH}_3 \cdot \text{CuSO}_4$. Di-K 4-benzoylnaphthalate fused with KOH at 210-20° and then acidified yields naphthalic anhydride, m. 269-70°, and BzOH. Treated rapidly in AcOH at 100-10° with $\text{Na}_2\text{Cr}_2\text{O}_7$, **I** gives, together with much **III**, a small amt. of α -benzoylacenaphthenequinone, golden yellow columns (from C_6H_6) or rhombic tables (from AcOH), m. 199-200°, very slightly sol. in alkalis, very easily in cold concd. H_2SO_4 with golden yellow color; trioxime, yellow amorphous powder, decomp. 94-6°. From **I** heated 1-2 hrs. at 200-10° with S is obtained a small amt. of dibenzoyldinaphthylene, Bordeaux-red, m. 213-5°; the chief product is tribenzoyltrinaphthylenebenzene (tribenzoyldecacylene) (best prepd. by raising the temp. during the heating with S to 250-60°), orange-red, m. 335-6°, sol. in concd. H_2SO_4 with blood-red color, mol. wt. in boiling PhNO_2 726-53 (the corresponding PhCH_2 derivs. were previously described erroneously as β -derivs. (*Bull. acad. sci. Cracovie* 1904, 201)). α' -Nitro- α -benzoylacenaphthene, from **I** in AcOH at 10-5° treated dropwise with HNO_3 (d. 1.48), lemon-yellow, m. 169-71°, sol. in concd. H_2SO_4 with intense red color, yields on fusion with KOH BzOH and a resinous mass insol. in alkalis; in AcOH with $\text{Na}_2\text{Cr}_2\text{O}_7$ on the H_2O bath it gives 5-nitro-4-benzoylnaphthalic anhydride, light yellow, m. 273°, converted by long heating with concd. NH_4OH on the H_2O bath into the imide, light yellow, m. 302-4° (decompn.) C. A. R.

Perylene and its derivatives. X. A. ZINKE AND K. FUNK (WITH J. MATSCHER, O. WOLFRAUER AND N. LÖRRER). *Ber.* 58B, 2222-7 (1925), cf. C. i. 19, 2335.—It was shown in earlier papers that isoviolanthrone (**I**) can be synthesized in various ways from perylene (**II**). In the method involving the baking of 3,9-dibenzoylperylen (**III**)

with AlCl_3 the yield of **I** is much diminished by simultaneous reduction processes effected by the **II** catalytically split off and it can be materially increased by adding to the reaction mixt. a suitable H acceptor. MnO_2 proved to be especially effective and with its aid the yield of **I** can be increased to 45%. As freshly pptd. MnO_2 reacts too vigorously, it is best to use the natural, finely powd. oxide. Its use, however, may often bring about secondary processes; e. g., the HCl liberated in the decompn. of the fusion mixt. may simultaneously chlorinate the final product. Thus, the 3,8-di-*p*-methoxybenzoylperylen (**IV**) formed from **II** and *p*- $\text{MeOC}_6\text{H}_4\text{COCl}$ by the Friedel-Crafts method gives on baking with AlCl_3 an alkali-insol. dimethoxyisoviolanthrone and a product difficultly sol. in alkalis, which is probably the di-HO compd. resulting from the hydrolysis of the MeO groups by the HCl liberated during the baking; if, however, MnO_2 is added, not only is the alkali-insol. product increased in yield but it now also contains halogen and its compn. corresponds to that of a chlorodimethoxyisoviolanthrone (**V**). The reaction whereby **I** is prepd. from dihalogen derivs. of **III** with alkalis in boiling PhNH_2 or quinoline has been applied

to the 3,9-di-*o*-, *m*- and *p*-toluyl-4,10-dichloroperlylenes (**VI**). **IV**, golden yellow, m. 319.5°, dissolves in concd. H_2SO_4 with pure corn flower-blue color. **V**, dark powder sol. in H_2SO_4 with blue-green color. *o*-**VI** (1.5 g. from 4 g. dichloroperlylene (**VII**), AlCl_3 and *o*- $\text{MeC}_6\text{H}_4\text{COCl}$ in CS_2), yellow, m. 351°, sol. in cold H_2SO_4 with red color changing to blue on heating; *m*-isomer (2.8 g. from 4 g. **VII**), brown-red, m. 334°, sol. in cold H_2SO_4 with violet-red color (blue in thin layers), changing to violet-blue on heating; *p*-compd. (2.5 g. from 4 g. **VII**), light yellow, m. 345°, sol. in cold H_2SO_4 with red color changing to violet-blue on warming. 2',2''-Dimethyl-3(CO),4,9(CO)-10-dibenzoyleneperlylene (dimethylisoviolanthrone) (**VIII**), (appended formula) from *o*-**VI** and powd. KOH in boiling quinoline and purified by treating with $\text{Na}_2\text{S}_2\text{O}_4$ in boiling 2', NaOH and pptg. hot with air, dark needles difficultly sol. in boiling PhNH_2 , PhNO_2 and quinoline with violet color, dissolves in concd. H_2SO_4 with a soft green color, 3',3''- or 5',5''- Me_2 isomer (0.8 g. from 2.2 g. *m*-**VI**), dark needles rather difficultly sol. in boiling PhNH_2 , PhNO_2 and quinoline with deep violet-blue color, sol. in H_2SO_4 with soft green color; 4',4''- Me_2 compd. (1.2 g. crude or 0.7 g. crystd. product from 2 g. *p*-**VI**), dark needles, sol. in boiling PhNH_2 , PhNO_2 and quinoline with violet-blue color, in H_2SO_4 with soft green color; the vat is intensely blue with red fluorescence and, like its isomers, dyes cotton bluish violet. **VII** with 1- $\text{C}_{10}\text{H}_7\text{COCl}$ and AlCl_3 in CS_2 gives only 3- α -naphthoyl-4,10-dichloroperlylene (**IX**), golden yellow, m. 275°, sol. in cold concd

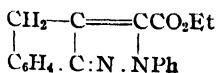

H_2SO_4 with blue-green color changing on heating to blue and then violet; with powd. KOH in boiling quinoline it gives a dark product, almost insol. in all solvents, rather difficultly sol. in concd. H_2SO_4 with green-blue color, which still contains halogen and forms an only very faintly dark blue vat dyeing cotton blue with a violet tinge. *3-β-Naphthoyl isomer of IX*, Cr-yellow, m. 293° , sol. in H_2SO_4 with green color, gives with KOH in boiling quinoline a substance sol. in moderately hot H_2SO_4 with blue-green color, which cannot be converted into a vat dye. **XI**. A. ZINKE, R. SPRINGER AND A. SCHMID. *Ibid* 2386–91.—It has been shown that dihaloperylenes with hot concd. H_2SO_4 are hydrolyzed, with elimination of HX, and oxidized and that in the case of the 3,10-Br₂ deriv. the product is 3,10-perylenequinone. The results of the present work indicate that the product obtained from 4,10-dichloroperylene is likewise 4,10-perylenequinone which, however, seps. as a very stable mol. compd. $(\text{C}_{20}\text{H}_{10}\text{O}_2)_2 \cdot \text{H}_2\text{O}$ (I), black-violet needles almost insol. in the lower boiling solvents, relatively sol. in boiling PhNH_2 with green color and formation of a compd. which has not yet been obtained in cryst. form, does not lose H_2O at $160\text{--}70^\circ$ *in vacuo*. The red soln. of I in concd. H_2SO_4 is changed by a little H_2O to green, much H_2O reprecip. the I. $\text{Na}_2\text{S}_2\text{O}_4$ converts I in dil. alkali into an orange-red to red (depending on the concn.) vat with intense yellow-green fluorescence, from which CO_2 pptts. the orange-yellow *hydroquinol*, very sensitive to air. The vat dyes cotton a faint orange-red changing in the air through brownish and olive-green to dull violet tones. Repeated recrystn. of I from PhNO_2 gives long graphite-like needles with 82.23–83.02% C, 3.34–4.08% H (av., 82.53, 3.70); distn. with Zn dust and ZnCl_2 gives perylene. The vat with BzCl gives 4,10-dibenzoylperylene-hydroquinol, brown-yellow m. 324° , mol. wt. in perylene (mol. depression 25.7°) by Rast's method 491–536; 4,10-di-*p*-bromobenzoyl analog, brown-yellow, m. $359\text{--}61^\circ$, mol. wt. in perylene 684–751, hydrolyzed by concd. H_2SO_4 on the H_2O bath to I.

C. A. R.

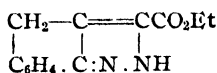

Constitution of naphthazarin. OTTO DIMROTH AND FRITZ RUCK. *Ann.* **446**, 123–31 (1925).—Naphthazarin (I) and pyroborooacetate in Ac_2O give a brick-red *di-borooacetate*, with a greenish metallic luster, which indicates that I must be 1,4-dihydroxy- and not 1,2-dihydroxy-5,8-naphthoquinone. The previous structure of I depends largely upon Will's synthesis (*Ber.* **28**, 2234 (1895)) in which he started from $\delta\text{-C}_{10}\text{H}_4(\text{NO}_2)_4$, assumed to be the 1,2,5,8-deriv. because it was obtained by further nitration of 1,2,5- and 1,5,8- $\text{C}_{10}\text{H}_5(\text{NO}_2)_3$. The 1,2,3-deriv., however, is shown to be a difficultly separable mixt. of several substances and is therefore to be stricken from the literature. The $\delta\text{-C}_{10}\text{H}_4(\text{NO}_2)_4$ is therefore the 1,4,5,8-deriv. 1,3,5- $\text{C}_{10}\text{H}_5(\text{NO}_2)_3$ and $\beta\text{-C}_{10}\text{H}_7\text{OH}$ form an equimol. compd., orange-red, m. $146\text{--}8^\circ$, not decompd. by 90% HCO_2H or AcOH but is decompd. by crystn. from MeOH . A mixt. of about equal parts of 1,3,5-(α)- and 1,4,5-(γ)- $\text{C}_{10}\text{H}_5(\text{NO}_2)_3$, crystd. twice from HCO_2H , m. $110\text{--}2^\circ$, while Will gave $112\text{--}3^\circ$ as the m. p. of the 1,2,5-deriv.

C. J. WEST

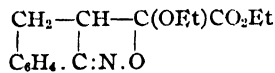

α -Hydrindone- β -oxalic ester. HERMANN LEUCHS AND GEORG KOWALSKI. *Ber.* **58B**, 2288–93 (1925).—From 13.2 g. α -hydrindone and 1 mol. $(\text{CO}_2\text{Et})_2$ at -15° slowly treated with Na in cold abs. alc. is obtained 18–20 g. *Et 1-hydrindone-2-oxalate* (I), faintly yellow, m. $71\text{--}2^\circ$, b_{10} 203° , sol. in H_2SO_4 with yellow color, dissolves only slowly in dil. alkalis, gives a brown-violet color with alc. FeCl_3 ; 1.16 g. with 2 mols. PhNH_2 at 100° gives 0.8 g. of the *unilide*, yellowish, m. $229\text{--}31^\circ$. Heated several hrs. *in vacuo* at 200° , I gives no or only very little gas and on distn. it is recovered unchanged; addn. of a little AlCl_3 or H_2SO_4 or heating to $260\text{--}90^\circ$ yields, together with some hydrindone,

(II)

(V)

(VI)

only resinous products. Free acid (1.9 g. from 2.32 g. I with 2 mols. N NaOH at $30\text{--}40^\circ$), yellowish, sinters 205° , m. about 215° (gas evolution), sublimes mostly undecompd. *in vacuo*, dissolves in hot NaOAc , NaHCO_3 and KHCO_3 , sepg. on cooling as the salt; at $220\text{--}30^\circ$ it loses CO and CO_2 . In 8 cc. abs. alc. with 0.36 g. PhNHNH_2 0.9 g. I yields 1.05 g. of an addn. compd., $\text{C}_{15}\text{H}_{20}\text{O}_4\text{N}_2$, sinters 90° , m. $95\text{--}6^\circ$, gives a brown color with alc. FeCl_3 , is insol. in but is altered by 5 N HCl , as well as by drying at 78° ; 1 g. allowed to stand 40 hrs. under 5 N HCl yields 0.3–0.4 g. of a pyrazole-like *anhydride* (probably II), m. $125\text{--}7^\circ$, and 0.4 g. of a *phenylhydrazone* (III) of I, greenish, sinters 150° , m. $156\text{--}8^\circ$. II seps. in long prismatic needles and in stout 4- and 6-sided tables into which the needles change but both forms can exist side by side for a long time. I (1.3 g.) refluxed 45 min. with 0.54 g. PhNHNH_2 in alc. yields 0.45 g. III and 0.37 g. of an isomer (IV), yellowish, m. $173\text{--}4^\circ$ (changing into III). III is unchanged by aq. 5 N HCl at

15° but with alc. HCl gives **II**, while **IV** is rapidly converted into **II** by the aq. acid. The semicarbazone of **I** occurs in only 1 form, m. 161–3°, gives no color with alc. FeCl₃ and with alc. HCl yields a *compd.* (probably **V**), m. 173–4°. Oxime of **I**, sinters 145°, m. 155–7°, gives no color with FeCl₃, yields with alc. HCl a *compd.* (probably **VI**), m. 61°. Attempts to alkylate **I** by boiling its Na salt in alc. with EtBr gave only hydrindone, which was also obtained by boiling the salt in alc. alone. C. A. R.

Reactions of the *meso*-hydroxyanthrones. M. A. MATTHEWS. *J. Chem. Soc.* 129, 236–45(1926).—OC(C₆H₅)₂CHOH (20 g.) in glacial AcOH is reduced by simultaneous addn. of Zn and concd. HCl to *dihydrodianthranyl* (**I**) (6 g.), m. 298–300°, exhibits an intense violet-blue fluorescence in org. solvents. Excess Br gives the *di-Br deriv.*, yellow, does not m. 320°, darkens on exposure to light and exhibits a blue fluorescence in soln. Excess HNO₃ gives a *NO₂ deriv.*, Au-yellow, m. 305° (decompn.), darkens on exposure to light. Dichlorodihydrodianthranyl (m. 268°, not 288° as reported in C. A. 18, 256), slowly heated with HNO₃ in glacial AcOH, gives *dichlorodinitrodianthranyl*, orange-red, does not m. 330°. OC(C₆H₅)₂CPhOH is reduced by Zn and HCl to diphenyldianthranyl. Dianthrol (**II**) is largely unchanged after boiling with Zn and HCl in AcOH for 3 hrs.; 3 g. **II** with Zn and NH₄OH gives 0.6 g. anthracene; 1 g. **II** and HI in AcOH give 0.9 g. anthrone; 5 g. **II**, boiled with Sn and HCl in AcOH, gives 0.8 g. **I**. Reduction of dianthraquinone with Zn and HCl gives dianthranol. 1-Chloro-9-anthrone and Ac₂O in C₆H₅N give *1-chloro-9-anthranyl acetate*, yellow, m. 110–2°; the EtOH solns. exhibit blue fluorescence. The *4-Cl deriv.* m. 124–6° and also shows a blue fluorescence in EtOH. *1-Chloro-10-bromoanthrone*, pale yellow, m. 165° (decompn.). Boiling with dil. Me₂CO gives *1-chloro-10-hydroxyanthranone* (**III**), m. 144–5°, whose alk. soln. is deep red; the *4-Cl deriv.* (**IV**), pale yellow, m. 144–5°. OC(C₆H₅)₂CHOH and HCl or OC(C₆H₅)₂CH₂ and Cl give *10-chloroanthrone*, m. 225° (gas evolution); it is stable towards boiling dil. alkali, is very slowly hydrolyzed by dil. Me₂CO and may be recrystd. from boiling C₆H₅Me₂. C₆H₅N gives *anthronylpyridinium chloride* (*10-hydroxyanthranyl-9-pyridinium chloride*), orange-red, m. 204° (decompn.). **IV** and HCl gas in C₆H₆ give *4,10-dichloroanthrone* (**V**), pale yellow, m. 125–8°, while **III** gives a mixt. of 1-chloroanthraquinone and 1-chloro-9-anthrone. Cl and 4-chloro-9-anthrone in CCl₄ contg. a crystal of **I** likewise give **V**, while 1-chloro-9-anthrone gives *4,4'-dichloro-9,9'-dianthrone*. OC(C₆H₅)₂CHOH, heated with H₂O for 20 min., gives anthraquinol. The products of the reaction of OC(C₆H₅)₂CHOH and the 2 *α*-chlorohydroxyanthrones with HBr, HCl, HI, Sn + HCl, H₂SO₄, and Al + H₂SO₄ are tabulated. C. J. WEST

Preparation of quinizarin. HARRY H. REYNOLDS AND LUCIUS A. BIGELOW. *J. Am. Chem. Soc.* 48, 420–2(1926).—The influence of time, amt. of H₃BO₃ and temp. on the yield of quinizarin has been studied. The recommended procedure consists in heating 115 g. *p*-ClC₆H₄OH, 300 g. C₆H₄(CO)₂O, 50 g. crystd. H₃BO₃ and 2000 g. 96% H₂SO₄ 3.5 hrs. at 200°; the yield is 74% of a product m. 199–200° (cor.). C. J. W.

The constitution of the phenylpyrrole of O. Fischer and E. Hepp. G. PLANCHER AND E. GHIGI. *Gazz. chim. ital.* 55, 757–9(1925).—In a recent paper P. and G. (C. A. 19, 2203) noted that benzene azo-*N*-phenylpyrrole (**I**) prepd. from *N*-phenylpyrrole, obtained by distg. aniline mucate m. 49–50°; and that the same deriv. (**II**) prepd. from *α*-phenylpyrrole m. 116° (and not at 112°; Khotinsky, Soloweitschik, C. A. 3, 2565). Fischer and Hepp (*Ber.* 19, 2251) reported that **I** m. 117°, but P. and G. thought that this product is identical with **II**. They have now repeated the work of F. and H. and the product obtained is indeed **II** and not derived from *N*-phenylpyrrole as stated by F. and H. The prepn. of *benzeneazo-α-phenylpyrrole* and *p-anisylazo-α-phenylpyrrole*, 140–1°, is described. E. J. WITZEMANN

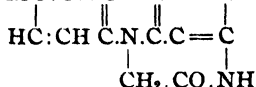

The thiophenes and intermediate products for their synthesis. (MISS) A. CHRZASZCZEWSKA. *Roczniki Chem.* 5, (1–3), 33–76(1925).—Various thiophene derivs. have been synthesized by Paal's method from salts of homologs of succinic acid. The yield is greatly increased by the addn. of sand to the reaction mixt. in quantity equal to that of the P₂S₅ used, the violence of the reaction being thereby considerably diminished. Better yields of 2-substituted thiophenes are obtained when the latter are more volatile, this being explained by the greater tendency to charring of the higher *γ*-keto acids. An excess of P₂S₅ has a deleterious effect on the reaction. The nitration of thiophenes has been investigated, and it is shown that the yield is quadrupled if AcCl is added to the nitrating mixt. of Ac₂O and HNO₃. 3-Phenylthiophene, m. 91–2°, was synthesized in the above way from Na phenylsuccinate, and from it *nitro-3-phenylthiophene*, pale yellow, m. 141°, was prepd., the nitro group being shown to be in the thiophene ring, and this on reduction gave *amino-3-phenylthiophene-HCl*. Pt black and H have practically no reducing action on 3-phenylthiophene. *3-p-Anisylthiophene*, m. 129°, was prepd. from *p-anisylsuccinic acid*, pale yellow, m. 189–90°, prepd. from *ethyl p-methoxy-*

benzylidenemalonate, m. 38–40°, obtained from the condensation of anisaldehyde with Et malonate. In the same way, *Et p-tolylidenemalonate*, m. 46–7°, is prepd., which gives on hydrolysis the *acid*, m. 184°, and from which *p-tolylsuccinic acid*, m. 192°, is prepd. From this, *3-p-tolylthiophene*, m. 111–2°, is obtained by the modified Paal method. 2-Methylthiophene is obtained in 62% yield in this way from Na levulate, as compared with 15% yield from the unmodified method; its *nitro deriv.*, yellow oil, $b_{88.5}$ 147.7°, is described. Similarly, 2-phenylthiophene is prepd. from Na benzoylpropionate in 30% yield, giving on nitration *nitro-2-phenylthiophene*, yellow, m. 74°, and on treatment with 1 *iodo-2-phenylthiophene*, pale yellow, m. 76–7°. 2-*p-Tolylthiophene*, m. 63–4°, obtained from *p-tolylpropionic acid*, and *p-hydroxyphenylsuccinic acid* (+1H₂O), m. 159°, from *Et p-hydroxybenzylidenemalonate*, m. 93°. B. C. A.

Influence of acetyl chloride on the nitration of acetanilide and dimethylaniline. A. CHRZASZCZEWSKA AND (Mlle.) M. BIATA. *Roczniki Chem.* 5, 77–95(1925); cf. preceding abstr. and Menk. *Ibid* 1, 386.—The nitration of AcNHPh and of PhNMe₂ has been studied, under various conditions and in various solvents. In particular, the effect of the addn. of AcCl as a dehydrating agent to the reaction mixt. has been investigated. In general, this increases the yield of nitro derivs., and, with PhNMe₂, increases the yield of *o*- at the expense of the *p*-nitro deriv. B. C. A.

Synthesis of substitution derivatives of indigo. I. *o*-Nitrobenzoylactic acid and related compounds. C. J. OVERMYER. *J. Am. Chem. Soc.* 48, 454–60(1926).—Several improvements are reported in the synthesis of indigo from *o*-O₂NC₆H₄COCl. Little or no hydrolysis occurs in the formation of O₂NC₆H₄COCH₂CO₂Et from O₂N-C₆H₄COCH(Ac)CO₂Et, since the reaction product gives with PhNHNH₂ a pyrazole instead of the expected pyrazolone. The constitution of the series of quinoline oxide derivs. obtained in the reduction of O₂NC₆H₄COCHAcCO₂Et is further established by the reduction of 2-methyl-4-hydroxyquinoline-3-carboxylic acid oxide (I), m. 214°, by Zn and HCl to the acid, m. 245° (decompn.), which loses CO₂ on heating, giving 2-methyl-4-hydroxyquinoline. I and Me₂SO₄ give the *4-methoxy deriv.*, m. 190°, does not reduce Fehling soln., gives an emerald-green soln. with KMnO₄ and a red color with FeCl₃. C. J. WEST

Derivatives of 1-aminocarbazole. HANS LINDEMANN AND FRANZ MÜHLHAUS. *Ber.* 58B, 2371–7(1925); cf. C. A. 19, 2824.—The prepn. of condensed systems in which the nucleus N atom of carbazole (I) is a member of the ring has finally been effected by starting with 1-derivs. of I. 3,6-Dibromocarbazole (II), m. 213°, from 50 g. I with 31 cc. Br in boiling CS₂. *N-Ac deriv.*, m. 189°; *N-NO deriv.*, light yellow, begins to turn brown 180°, m. 192° (decompn.), loses its NO group on mere warming with alc. HCl or boiling in aq. alc.; *N-Me deriv.*, m. 158–60°, forms, when fused with I, a deep blue melt. 1-*NO₂ deriv.* (II) (40 g. from 50 g. I and HNO₃ (d. 1.4) in boiling AcOH), yellow-red, m. 260°, sol. in alc. alkali with formation of a deep blue-red salt hydrolyzed by H₂O; II is also obtained from 1-nitrocarbazole with Br in CS₂. *N-Me deriv.* of II, yellow, m. 221°, gives no color with alc. alkali. II is reduced by Na₂S₂ in boiling alc. or by SnCl₂ in boiling AcOH to the 1-NH₂ compd. (III), m. 192°, which with HNO₃ forms amorphous, brown-red, non-homogeneous products, does not couple with phenanthrenequinone in either alc. or AcOH; *Bz deriv.*, m. 273° (blackening), becomes electrified when rubbed on glass; *Ac deriv.*, forms no benzimidazole derivative on heating with AcOH-HCl, POCl₃ or P₂O₅; *ω-chloroacetyl deriv.* (8 g. from 74 g. III with ClCH₂COCl in hot C₆H₆), m. 265–7°, this, refluxed in aq. alc. KOH, gives 3,6-dibromocarbazole-1,9-[3'-ketopiperazine], BrC:CH.C—C.CH:CB_r, darkens above 300°, m. 333°, converted by

NaNO₂ in boiling AcOH into the 2',3'-diketo compd., m. 435°, which with 50% KOH on the H₂O bath regenerates III. 3,6,8-Tribromocarbazole (IV), from I and somewhat more than 3 mols. Br in boiling CS₂, m. 184°, forms with 1 mol. Br in hot AcOH the tetra-Br compd., m. 220°. 1-*NO₂ deriv.* of IV (11 g. from 10 g. IV), intensely yellow, m. 264°, dissolves in alc. alkali with deep blue-red color. 1-NH₂ compd., m. 239°; *Ac deriv.*, m. 305°; *ω-chloroacetyl deriv.*, m. 285°, gives with alc. KOH 3,6,8-tribromocarbazole-1,9-[3'-ketopiperazine], m. 375°. C. A. R.

Quarternary salts of benzoxazoles. I. M. CLARK. *J. Chem. Soc.* 1926, 232–6.—Benzoxazole methiodide, yellow, m. 202° (decompn.); Fischer (*J. prakt. Chem.* 70, 435 (1906)) gives 182°; the aq. soln. is acid to litmus, from which, after addn. of 1 equiv. of KOH, there seps. *o*-formylmethylaminophenol, m. 103–4°; hydrolysis gives *o*-Me-NHC₆H₄OH, whose *NO deriv.* m. 125–6°. 1-Methylbenzoxazole methiodide, m. 196°

(decompn.); NaClO_4 gives the *methoperchlorate*, m. 173° ; aq. KOH or Ag_2O in Me_2CO transforms the methiodide into $\text{HOC}_6\text{H}_4\text{NMeAc}$, m. 151° ; at room temp. the methiodide was completely hydrolyzed by H_2O in 66 hrs. 1-Phenylbenzoxazole methiodide, m. 196° (decompn.); hydrolysis gives *o*- $\text{HOC}_6\text{H}_4\text{NMeBz}$, whose *urethan* m. 144° . With Me_2SO_4 the methiodide gives *o*-benzoylmethylaminoanisole, m. 115° , also prepd. from BzCl and *o*-methylaminoanisole. Attempts to reverse the hydrolysis by passing dry HI through *o*- $\text{HOC}_6\text{H}_4\text{NMeBz}$ in Et_2O or by dissolving *o*- $\text{HOC}_6\text{H}_4\text{NMeAc}$ in concd. HClO_4 failed.

C. J. WEST

Thiazoles. X. Synthesis of some 2-phenylbenzothiazolearsonic acids. M. T. BOBERT AND H. B. CORBITT. *Proc. Nat. Acad. Sci.* **11**, 768-72(1925); *Ch. C. A.* **20**, 600.—Diazotized 6-amino-2-phenylthiazole in H_2SO_4 , treated with AcONa and then poured into a suspension of KAsO_2 and Cu bronze in KOH , gave 5.4% of 2-phenylbenzothiazole-6-*arsonic acid*, yellow needles, does not m. 310° . 2-[*p*-Aminophenyl]benzothiazole, treated in like manner, gave 25.9% of 2-phenylbenzothiazole-*p*-*arsonic acid*, pale yellow, does not m. 302° . Nitration gives 91% of a *mono-NO_2* deriv., dull yellow powder, which is reduced by FeSO_4 and alkali to the *NH_2* deriv., grayish green powder (24.3% yield); its H_2O and EtOH solns exhibit green fluorescence; the diazotized product gives a cherry-red dye with $\beta\text{-C}_{10}\text{H}_7\text{OH}$. Preliminary expts. indicate that the compd. has a somewhat greater, though slower, action upon *Tr. equiperdum* than the corresponding C_6H_6 deriv., and also a greater toxicity for the white rats used in the expts. No evidence of any effect upon the nervous system was noted. 2-[*p*-Hydroxyphenyl]benzothiazole-*arsonic acid*, dark chocolate color, 46.7% yield.

C. J. WEST

2-Thio-3-[2-*p*-xylydyl]-4-ketothiazolidone and some of its derivatives. R. M. HANN. *J. Wash. Acad. Sci.* **16**, 31-5(1926).—*NH_4* 2-*p*-xylyldithiocarbamate, yellow, with a marked disagreeable odor, decomps. in the air to a yellow oil, with $\text{BrCH}_2\text{CO}_2\text{Et}$ gives 70% of 2-thio-3-[2-*p*-xylydyl]-4-ketothiazolidine, yellow, m. $119-20^\circ$ (cor.). *Benzal deriv.*, brilliant yellow, m. $188-9^\circ$ (cor.); the concd. H_2SO_4 soln. is brilliant red. *Cinnamal deriv.*, orange-yellow, m. $194-5^\circ$ (cor.); with Br this gives the α,β -*dibromo- β -phenylpropional deriv.*, yellow-brown, m. $119-20^\circ$ (cor.). *Vanillal deriv.*, bright yellow, m. $155-6^\circ$ (cor.); the concd. H_2SO_4 soln. has a brilliant red color. *Bromovanillal deriv.*, golden brown, m. $192-3^\circ$ (cor.); concd. H_2SO_4 soln., bright red.

C. J. WEST

Pyrogenic processes in the transformation of the *o*-aminoazo compounds into triazoles. G. B. CRIPPA. *Gazz. chim. ital.* **55**, 706-11(1925).—The 2-*N*-aryltriazoles (I) are obtained from the corresponding *o*-aminoazo compds. (II) by closing the ring

thus: $\text{H}_2\text{NArN:NAr}' \longrightarrow \text{Ar} \begin{array}{c} \diagup \text{N} \diagdown \\ | \\ \diagdown \text{N} \diagup \end{array} \text{NAr}'$. Among the various methods suggested

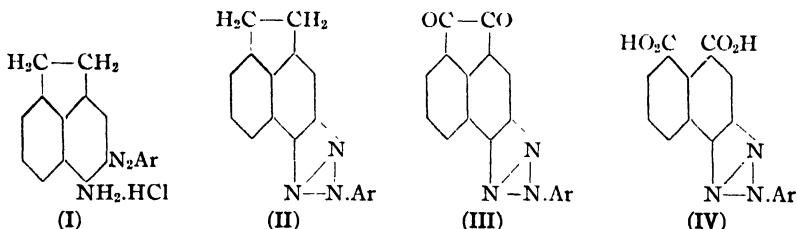

the Chem. Fab. Griesheim-Elektron (D. R. pat. 273,443(1913)) has boiled II in PhNO_2 in the presence of Cu and Fe powder and C. has now tried other media for this purpose. The results showed that the velocity of the transformation depends on the b. p. of the solvent used and not on an oxidizing action of the PhNO_2 . Charrier (*C. A.* **5**, 1744)

found that II decomps. thus: $3\text{H}_2\text{NArN:NAr}' \longrightarrow 2\text{Ar} \begin{array}{c} \diagup \text{N} \diagdown \\ | \\ \diagdown \text{N} \diagup \end{array} \text{NAr}' + \text{Ar}'\text{NH}_2 +$

o- $\text{Ar}(\text{NH}_2)_2$ and C. found that when vaseline oil was used the *o*-diamine could be isolated readily if the reaction is completed quickly but not in other cases. The free H formed in closing the ring reacts with unchanged mols. of II, reducing them to the amines given. Heating for 10 min. with oil of vaseline (b. 280°) gives about the same result as heating 10 hrs. with PhNO_2 or 50 hrs. with turpentine (b. 155°) except that less tar is formed. *p*-Chlorophenylazo- β -naphthylamine gave negative results with some solvents including PhNO_2 but 2,*N*-*p*-chlorophenyl-1,2-naphthotriazole was readily obtained from it when vaseline oil was used. 5 g. pseudocumylazo- β -naphthylamine in 40 cc. vaseline oil and 0.7 g. powd. Cu were boiled 15 min. The liquid was filtered and on standing sepd. a brown mass from which *o*- $\text{C}_{10}\text{H}_6(\text{NH}_2)_2$ was extd. with boiling H_2O . Traces of basic compds. were removed by boiling with dil. HCl . The residual mass was 2-*N*-2',4',5'-trimethylphenyl-1-2-naphthotriazole (2,*N*-pseudocumyl-1,2-naphthotriazole). The vaseline oil was steam-distd. and yielded pseudocumidine, which was identified by diazotization and copulation with $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$ as pseudocumylazo- β -naphthylamine. E. J. W.

***o*-Aminoazo compounds and 1,2,3-acenaphthenic triazoles.** G. CHARRIER AND A. BERETTA. *Gazz. chim. ital.* **55**, 745-54(1925).—Previous experience permitted C. and B. to predict that diazonium salts would react with 5-aminoacenaphthene (*periethylene- α -naphthylamine*), giving 4-arylazo-5-aminoacenaphthenes (I) which sep. as HCl salts. I are oxidized and transformed into the corresponding 2-*N*-aryl-1,2,3-triazoles (II) and on reduction give 4,5-diaminoacenaphthene. I are quite stable and

give several reactions of acenaphthene such as the oxidation to 2-*N*-aryl-4,5-triazolacenaphthenequinone (III) and 2-*N*-aryl-3,4-triazonaphthalic acid (IV). I are garnet-red, very stable, sol. in org. solvents, sep. in cryst. form, and are easily oxidized to II. II are quite similar to the naphthalenic 1,2,3-triazoles; they are colorless and less sol. in org. solvents than I. A soln. of PhN₂Cl (treated with urea to remove HNO₂) with an equimol. amt. of 5-aminoacenaphthene in EtOH sepd. a HCl salt which, decompd. with dil. NH₄OH, gave 4-phenylkuzo-5-aminoacenaphthene (V) m. 140°. V with alc. Na₂S₂O₄

gave PhNH₂ and 4,5-C₁₂H₈(NH₂)₂, m. 140–2°. V oxidized with ammoniacal Cu soln. (Schmidt, Hagenböcker, *C. A.* 16, 1092) gave 2-*N*-phenyl-4,5-acenaphtho-1,2,3-triazole (VI). 10 g. VI in glacial AcOH with 40 g. Na₂Cr₂O₇ heated a few min. sepd. 2-*N*-phenyl-4,5-triazolacenaphthenequinone (VII), m. 268°, which was converted into the corresponding phenylhydrazone, m. 254°; with *o*-C₆H₄(NH₂)₂ it gives the corresponding phenazine, m. 300°. VII with alk. KMnO₄ gives 2-*N*-phenyl-3,4-triazolacenaphthalic acid, m. 218°. The following compds. were obtained by similar methods: 4-*o*-tolylazo-5-aminoacenaphthene, m. 175°; 2-*N*-*o*-tolyl-4,5-acenaphthotriazole, m. 100°; 4-*m*-tolylazo-5-aminoacenaphthene, m. 171°; 2-*N*-*m*-tolyl-4,5-acenaphthotriazole, m. 181°; 4-*p*-tolylazo-5-aminoacenaphthene, m. 154°; 2-*p*-tolyl-4,5-acenaphthotriazole, m. 198°; 4-*s*-pseudocumylazo-5-amino-acenaphthene, m. 170°; 2-*N*-*s*-pseudocumyl-4,5-acenaphthotriazole, m. 150°; 4-*p*-nitrophenylazo-5-aminoacenaphthene, m. 195°; 4-*p*-chlorophenylazo-5-amino-acenaphthene, m. 184°; 2-*N*-*p*-chlorophenyl-4,5-acenaphthotriazole, m. 223°; 4-*p*-bromophenylazo-5-aminoacenaphthene, m. 185°; 2-*N*-*p*-bromophenyl-4,5-acenaphthotriazole, m. 231°.

E. J. WITZEMANN

Mechanism of the formation of triphenylguanidine and phenylthiocarbimide from thiocarbanilide. S. J. C. SNEDEKER. *J. Soc. Chem. Ind.* 44, 547–8T(1925).—From a consideration of the various methods of prepg. (PhNH)₂C:NPh from (PhNH)₂CS, it is concluded that the tautomeric form, HSC(Ph)NPh, reacts to form an unstable reaction product, PhNHCSNPhC(NPh)NPh and H₂S; this then decomps. into PhN:CS and (PhNH)₂C:NPh. Me₂SO₄ and (PhNH)₂CS give the *S*-Me deriv., m. 109°. (PhNH)₂CS and AcNNAph in CS₂ give the *Na* salt of thiocarbanilide, pale yellow, m. 70°; in contact with the skin, it causes a severe form of eczema. C. J. WEST

Action of sulfuryl azide on benzene. K. F. SCHMIDT. *Ber.* 58B, 2409–12(1925); cf. Curtius and S., *C. A.* 17, 1000.—In order to obtain larger amts. of material the glass app. used in the earlier work was replaced by a spacious Cu autoclave and a total of 250 g. N₂SO₂N₂ in 50 parts dry C₆H₆ was heated, in 12 portions, 1 hr. at 140°; the av. resultant pressure was 14 atm. Half of the product was worked up for the free base (I) (designated in the earlier paper as “pseudoaniline”) (yield, 3 g. b. 114–5°), the other half for the picrate (6 g. crude product, m. 160°). It was established with certainty, by analysis, mol. wt. detns. and prepn. of derivs. (methiodide and its chloroplatinate) that I is C₆H₅N. This is confirmed by the work of Curtius and Bertho (*Sitz. Heidelberger Akad. Wiss., Abt. A*, 1924–5), who obtained small amts. of C₆H₅N and α,α' -lutidine, resp., from C₆H₆ and *p*-xylene with N₂CON₃. C. A. R.

Condensation of 3-bromo- and 3-nitro-4-dimethylaminobenzaldehyde with ethyl acetoacetate and ammonia. L. E. HINKEL AND WM. R. MADELL. *J. Chem. Soc.* 1926, 161–3.—3,4-Br(Me₂N)C₆H₃CHO (1 mol.), 2 mols. AcCH₂CO₂Et and 1 mol. EtOH-NH₃ give 82% of Et 4-[*m*-bromo-*p*-dimethylaminophenyl]-2,6-dimethyl-1,4-dihydropyridine-3,5-dicarboxylate, yellowish white, m. 133°; nitrous fumes oxidize it to the corresponding pyridine deriv., pale yellow, m. 91°. The corresponding *m*-nitro derivs. deep yellow, m. 127° (70% yield) and yellow, m. 109°, resp. C. J. WEST

Action of isobutyl- and phenylmagnesium halides on quinoline methiodide. JAKOB MEISENHHEIMER, ERWIN STOTZ AND KARL BAUER. *Ber.* 58B, 2320–30(1925); cf. *C. A.* 17, 3341.—As already shown for 1-methyl-2-propyltetrahydroquinoline, so also Freund and Kessler's supposed stereoisomeric forms of the 2-iso-Bu analog are really homologs. Quinoline-MeI and iso-BuMgBr give 1-methyl-2-isobutyl-1,2-dihydroquinoline (I)

which dists. undecompd. *in vacuo* but under atm. pressure splits off CH_4 and changes into 2-isobutylquinoline (II). Reduction converts I and II into the corresponding tetrahydro derivs. and it is these 2 compds. which are F. and K.'s supposed stereoisomers. I, obtained in about 40% yield, b_{12} 143–4° (in H), is a red-yellow oil of unpleasant odor, decomp. on standing, dissolves in acids without color and not with a red color, as stated by F. and K.; the orange-yellow picrate, m. 92–4°, soon becomes brown to black in daylight, cannot be recovered unchanged from any solvent, always giving, together with resinous products, a dark red picrate (the picrate, m. 154–5°, described by F. and K. was somewhat impure II picrate). II, faintly yellowish oil of not unpleasant odor, b_{23} 157°, sol. in acids without color, is obtained as the lemon-yellow picrate, m. 161° (yield of crude product, 20 g.), from 17 g. I refluxed 5 hrs., distd. under 12 mm. and treated with hot alc. picric acid; methiodide, yellow, m. 186°, sol. in org. solvents with yellow, in H_2O with no color 2-Isobutyl-1,2,3,4-tetrahydroquinoline (III) (8.6 g. from 10 g. II with Sn and HCl), b_{16} 157–8°; b_{20} 159–60°; HCl salt, m. 217° (F. and K. give 223–4°), sublimes without decompn.; methiodide, m. 158–9° (F. and K., 168°), hydrolyzed by H_2O , the resulting oil giving with picric acid the picrate, m. 150°, of 1-methyl-2-isobutyl-1,2,3,4-tetrahydroisquinoline (IV); picrate of III, from the components in alc., m. 130–1° (if the reaction is carried out in H_2O the picrate seps. with $1\text{H}_2\text{O}$ and m. around 68–72°). IV (6–7 g. from 11 g. I with Na and alc.), light yellow oil, b_{18} 157°, purified through the golden yellow picrate, m. 150°; methiodide, m. 146° (151° on rapid heating; F. and K. give 174°). 1-Methyl-2-phenyl-1,2-dihydroquinoline (V), m. 88–9°, is obtained in 80% yield from quinoline-MeI with 1.5 mols. PhMgBr ; it is quite unstable, resinifying on long warming with solvents, and on standing its m. p. gradually falls. With an equal wt. of picric acid in alc. or Et_2O at room temp. it gives 80% of a bright red substance (VI), m. about 130°, which has the compn. of the expected 1,2-dihydroquinoline picrate but which is insol. in Et_2O and can be sepd. by fractionation from hot alc. or AcOH into 1-methyl-2-phenylquinolinium picrate (VII), m. 136–9°, and a deep red picrate (VIII), m. 140°, having the same compn. as VI and corresponding in every respect to that described in the earlier paper, where it was assumed to be an indole picrate; M., S. and B. now believe, however, that it is a 1,4-dihydroquinoline picrate. VIII is obtained in considerably better yield (80%) from VI when the VI is cautiously dissolved in cold Me_2CO and pptd. with ligroin; it is perfectly stable towards boiling alc., from which it can be recrystd. unchanged. VI, therefore, cannot consist exclusively of VIII but must contain an admixt. which on soln. in cold Me_2CO changes into VIII and with boiling alc., on the other hand, gives VII. This admixt. can hardly be anything else but the 1,2-dihydroquinoline picrate, which must be assumed to be of itself easily sol. in Et_2O and alc. but, in the presence of VIII, to sep. with the latter as a double compd. The above view is supported by the fact that the transformation of the original yellow picrates, which with alkalis regenerate the 1,2-dihydroquinolines, into the red picrates, which do not, can no longer be effected when the free 2-H atom necessary for the change of the 1,2- into the 1,4-dihydro bases is substituted, as in 1,2,2-trimethyl-1,2-dihydroquinoline, which gives in good yield a pure yellow picrate undergoing no change of any kind on recrystn. That the 1,4-dihydroquinoline picrates are red is probably due to the fact that the 1,4-dihydroquinolines are such weak bases that they cannot form normal picrates but form addn. compds. in Pfeiffer's sense. NaOH resinifies VIII while HCl converts it into VII. Treated in a little H_2O with Na_2CO_3 , VIII yields a 1-methyl-2-phenyl-1,4-dihydroquinoline-Na picrate double compd., $\text{C}_{16}\text{H}_{15}\text{N} \cdot \text{C}_6\text{H}_5\text{O}_2\text{Na} \cdot \text{Na}$, m. 170°, also formed, but very slowly and in impure state, when Me_2CO or alc. solns. of V and Na picrate are mixed; with HCl it regenerates VIII. Heated 8 hrs. on the H_2O bath in 20% HCl, cooled and treated with H_2O , 1 g. V gives 0.6 g. of a light red ppt., about 0.5 of which dissolves in Et_2O , leaving a substance, m. 160–2°, which is apparently a polymer of V. Heated in CO_2 at 250°, 2 g. V evolves CH_4 and gives about 1 g. of a resinous substance (probably a polymerization product) and 0.6 g. 2-phenylquinoline (IX), m. 82°, whose picrate m. 187° and methiodide m. 197°; the latter does not decomp. on recrystn. and with picric acid in alc. gives VII. Reduction of IX with Sn and HCl for 8–10 hrs. gives 65% of the 1,2,3,4-tetrahydro deriv. (X), b_{24} 218–20°, whose picrate, m. 129–30°, regenerates pure X with NaOH . 1-Bz deriv. of X, m. 124–5°. As found by Freund (Ber. 37, 4670(1904)), bromination of V gives bromo-2-phenylquinolinium methobromide, $\text{C}_{16}\text{H}_{15}\text{NBr}_2$, m. 248–50°, whose yellow picrate, m. 168–9°, is perfectly stable and can be recrystd. from alc. and 50% AcOH . C. A. R.

Dihydroquinolines. JAKOB MEISENHEIMER AND ERWIN STOTZ. Ber. 58B, 2330–3 (1925).—Brief discussion of the structures and properties of the 3 classes of dihydroquinolines described in the literature—those of Freund, of Heller and of R  th. R. supports the structure he assigns his compds. on the supposed identity of the product

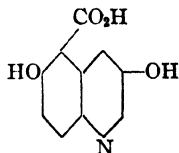

he obtained from *o*-MeC₆H₄NHMe and MeCHBrCH(OEt)₂ (C. A. 18, 2898) with the 1,2-dimethyl-1,2-dihydroquinoline obtained by Freund from quinoline-MeI and MeMgI. The work of both was repeated; F.'s method gave more than 80% of a light yellow oil, b₁₄ 128.5°, which undoubtedly has the structure assigned to it by F.; like all such 1,2-dihydro bases it gives in cold alc. and Et₂O a well-crystd. yellow picrate, m. 130°, showing the characteristic property of these picrates of gradually changing in the solid state through orange to brown, of at once becoming red in solvents and of not being recrystallizable without change. R.'s method, on the other hand, gave a fraction b_{14.5} 125–35°, forming no cryst. picrate in alc.; in Et₂O it gave a light yellow picrate, m. 175–8°, which could be recrystd. from alc. and showed no tendency to change. The fore- and after-fractions, b_{14.5} 103–20° and 137–60°, resp., gave yellow picrates, m. 185–200° and 140–60°; the whole product is evidently a very complex mixt. and certainly different from F.'s compd., so that for the present it is quite uncertain whether R.'s compds. have the structures he assigned to them.

C. A. R.

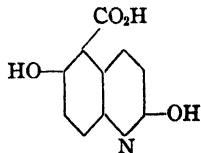

Quinaldine oxide. JAKOB MEISENHEIMER and ERWIN STOTZ. *Ber.* 58, 2334–5 (1925).—The supposed γ -ketohydroquinaldine (I) obtained by Heller and Sourlis by gentle reduction of *o*-nitrophenyllactic acid Me ketone (C. A. 2, 3352) seps. from H₂O with 2 mols. solvent, 1.5 of which it loses *in vacuo* over H₂SO₄; at 63° *in vacuo* it again loses in wt. but at the same time sublimes; after 2 hrs. it is practically anhyd. The last 0.5 mol. of H₂O is held very firmly and is not dissociated away by soln. in anhyd. solvents ((CH₂Br)₂, C₆H₆), as shown by mol. wt. detns. I is also obtained in good yield from quinaldine with BzO₂H in C₆H₆ and M. and S. believe that it really is *quinaldine N-oxide*; the acid obtained by energetic oxidation of I would then be a *quinoline N-oxide-2-carboxylic acid*.

C. A. R.

The occurrence of dihydroxyquinolinecarboxylic acid (the β -acid of Suzuki) in rice bran. Y. SAHASHI. *Biochem. Z.* 159, 221–34 (1925).—The β -acid of Suzuki (I) (C. A. 6, 2774) has been obtained in large amts. (300 g.), and its properties and chem. structure have been detd. On heating I at 100°, an indefinite amt. of H₂O is lost, but at 150°, 1 mol. is driven off, giving the anhyd. acid, C₁₀H₇NO₄ (II) which changes at 150° to orange-yellow and at 300° to brown, but does not change again up to 315°. It burns with partial sublimation. The following salts are prepd.: (C₁₀H₆NO₄)₂.Cu.2H₂O, (C₁₀H₆NO₄)₂.Ba.2H₂O, C₁₀H₆NO₄Na, C₁₀H₆NO₄K, besides basic salts of Ag, Na, NH₄ and Ca. It gives a mono-Bz or Me ester, a diacetate, and a tri-Bz deriv. One of the Bz groups is present as an anhydride, so that the acid is monobasic and contains 2 groups which are phenolic. Bromination of the Cd salt gives a salt (C₁₀H₆NO₄.Br.HBr)₂.CdBr₂. By the action of HNO₃ on II, is obtained dinitro-3-hydroxybenzene-1,2-dicarboxylic acid (juglone acid), and (CO₂H)₂, while distn. with Zn dust gives quinoline. Therefore, I is either

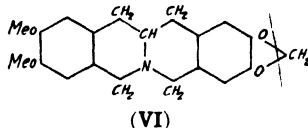

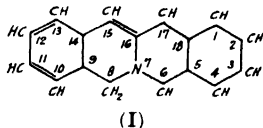

or

W. D. L.

Synthetical experiments in the isoquinoline group. VI. Synthesis of derivatives of parabarine. RAY CAMPBELL, R. D. HAWORTH and WM. H. PERKIN, JR. *J. Chem. Soc.* 129, 32–43 (1926); cf. C. A. 19, 2958.—The substance I is termed *parabarine*. An alkaloid of this type has been synthesized with this skeleton in order to compare the ease of formation and general properties with those of the alkaloids met with in nature. 3,4-Dimethoxyphenyl 3,4-methylenedioxy- β -phenylethyl ketone, m. 102–3°, gives an *oxime*, m. 119–21°, and an *isomeroso deriv.* (II), m. 137°. It is not reduced by Zn and AcOH at 60° but SnCl₂ and HCl in EtOH give 3,4-dimethoxyphenyl 3,4-methylenedioxy- β -phenyl- α -aminoethyl ketone, isolated as the SnCl₄ salt and analyzed as the HCl salt (III), m. 218–9°, and the yellow *picrate*; attempts to isolate the free base gave the *pyrazine*, pale yellow, m. 205°; this is best prepd. from II in NaOH with Zn dust. III in MeOH and 40% HCHO, decompd. with NaHCO₃, boiled 20 min., washed free from HCHO and digested with 20% HCl, gives 6,7-methylenedioxy-3-[3',4'-dimethoxybenzoyl]-1,2,3,4-tetrahydroisoquinoline, m. 137°; HCl salt, m. 232–4° (decompn.), *crystg.* with 2 mols. H₂O, m. 115–20°; *Bz deriv.*, m. 187–8°; *picrate*, yellow, with 1H₂O, m. 167–8°; *oxime*, m. 205–9° (decompn.). Oxidation with I in EtOH contg. KOAc gives, 6,7-methylenedioxy-3-[3',4'-dimethoxybenzoyl]isoquinoline (IV), m. 222°; *sulfate*, pale yellow

plates dissociated by H_2O ; *oxime*, m. $234-6^\circ$ (decompn.); fusion with KOH gives veratric acid. Reduction with Zn dust in AcOH gives the 3-[α -hydroxy-3',4'-dimethoxybenzyl] deriv., m. 153° ; *picrate*, yellow, darkens 183° , m. 195° (decompn.). HBr and Zn dust probably give 6,7-methylenedioxy-3-[3',4'-dimethoxybenzyl]isoquinoline, whose *picrate*, yellow, m. $206-7^\circ$. Electrolytic reduction of IV in 10% H_2SO_4 gives 6,7-methylenedioxy-3-[3',4'-dimethoxybenzyl]-1,2,3,4-tetrahydroisoquinoline, whose HI salt (V) m

226° (decompn.); HI salt, m. $220-2^\circ$ (decompn.); *nitrosamine*, m. 128° . V in MeOH, decompd. with $NaHCO_3$ and treated with $HClO$ and HCl, gives a very small yield of 2,3-methylenedioxy-11,12-dimethoxy-6,15,16,17-tetrahydroparaberine (VI), m. $221-2^\circ$; HI salt, m. $236-8^\circ$; *picrate*, yellow, m. $199-201^\circ$; *methiodide*, m. 268° ; *methochloride*, m. 260° (decompn.). Oxidation with I in EtOH gives 2,3-methylenedioxy-11,12-dimethoxy-6,17 (or 6,15)-dihydroberberine, pale yellow, amorphous powder, m. $180-90^\circ$, III-salt, pale yellow, m. $225-6^\circ$; HI salt, bright yellow, with $0.5H_2O$ of crystn., m. 120° .

C. J. WEST

Transformation of 2,4-dinitro-4'-phenylazodiphenylamine into derivatives of phenazine. A. BERETTA. *Gazz. chim. ital.* **55**, 711-3 (1925).—Sixty g. Sn and 160 g. HCl in a porcelain dish were treated with 36.2 g. powd. 2,4-dinitro-4'-phenylazodiphenylamine (I) (cf. Beretta, C. A. **18**, 1477). The mixt. was kept on the H_2O bath at not over 70° . When the soln. has become limpid H_2O is added, the temp. is made 40° and Zn is added to ppt. the Sn. The filtrate is satd. with $CaCO_3$. The liquid obtained is cooled and treated with 35 g. $K_2Cr_2O_7$ in H_2O . The colored soln. is filtered, treated with NaCl which ppts. aminophenosafuranine (I), m. 360° after repeated crystn. from boiling H_2O , identical with that obtained by Ris (*Chem.-Ztg.* 305 (1893)). I on reduction gives equimol amts. of $PhNH_2$ HCl and 2,4,4'-triaminodiphenylamine, which with CrO_3 react to give I. 6 g. 2-amino-4-nitro-4'-phenylazodiphenylamine (for prepn., cf. B. I. c.) were dissolved in hot EtOH and acidified with 0.5 cc. HCl. This soln. was poured into 3.75 g. phenanthrenequinone in glacial AcOH at 100° . After heating on the H_2O bath for some time the soln. was allowed to stand and evap. for some days. The concd. liquid was dild. with H_2O + AcOH. Nitrophenylazoflavinduline chloride, m. $146-8^\circ$, is pptd.

E. J. WITZEMANN

The dioximes. XXVII. G. PONZIO AND G. PEROLIO. *Gazz. chim. ital.* **55**, 688-98 (1925); cf. C. A. **20**, 746.—Since $PhC(:NOH)C(:NOH)Cl$ (I) (C. A. **17**, 2268) reacts with NH_3 and $PhNH_2$ with the substitution of Cl it was thought that $PhNHNH_2$ would react giving phenylphenylhydrazinoglyoxime (II) but the reaction was more complex and the compd. formed had the compn. of II less $1H_2O$, but was not the corresponding furazan, azoxime or the oxadiazole that might have been formed. It was concluded that 2,6-diphenyl-3-keto-2,3,4,5-tetrahydrotetrazine (III) was formed. 5 g. I suspended in 30 cc. EtOH was treated with 6 g. $PhNHNH_2$. The product was filtered off and washed with H_2O to eliminate $PhNHNH_2$. The residue of III, m. $174-5^\circ$ (decompn.), is stable in hot 20% NaOH but is decompd. in dil. HCl. III with Ac_2O in the cold gives the *mono-Ac* deriv., $C_{14}H_{11}ON_4Ac$, m. 161° ; heated with Ac_2O and NaOAc it gives the *di-Ac* deriv., m. 174° . III in hot 50% AcOH treated with CrO_3 , pptd. *sym.-2,6-diphenyl-3-keto-2,3-dihydrotetrazine* (IV), m. $264-5^\circ$. IV in boiling AcOH was treated with Zn dust and poured into H_2O . The ppt. was dissolved in Et_2O-HCl On adding H_2O *sym.-2,6-diphenyl-2,3,4,5-tetrahydrotetrazine* (V), m. 86° , was pptd. V in AcOH with CrO_3 pptd. *sym.-2,6-diphenyl-2,3-dihydrotetrazine*, m. $238-9^\circ$. I treated as in the prepn. of III with *p*- $BrC_6H_4NHNH_2$ gave *sym.-6-phenyl-2-p-bromophenyl-3-keto-2,3,4,5-tetrahydrotetrazine*, m. $189-90^\circ$; heated with Ac_2O it gives the *di-Ac* deriv., $C_{14}H_9ON_4BrAc_2$, m. $169-70^\circ$. Finely powd. β -*p*-tolylglyoxime (Avogadro, C. A. **18**, 661) suspended in $CHCl_3$ and treated with dry Cl_2 to satn. gave *p*-tolylchloroglyoxime (VI), $MeC_6H_4C(:NOH)C(:NOH)Cl$, m. 201° (decompn.); the Ni salt, $(C_6H_5O_2N_2Cl)_2Ni$, seps. as orange crystals that blacken at 180° but do not melt; in the cold with Ac_2O it gives the *di-Ac* deriv., m. 95° . VI treated with $PhNHNH_2$ as with III gave *sym.-2-phenyl-6-p-tolyl-3-keto-2,3,4,5-tetrahydrotetrazine* (VII), m. $190-1^\circ$; heated with Ac_2O it gives the *di-Ac* deriv., m. 170° . VII in AcOH with a suspension of H_2O-CrO_3 gave *sym.-2-phenyl-6-p-tolyl-3-keto-2,3-dihydrotetrazine* (VIII), m. 265° . VIII in boiling AcOH with Zn dust gave *sym.-2-phenyl-6-p-tolyl-2,3,4,5-tetrahydrotetrazine*, m. 104° , and this

in AcOH soln. with CrO_3 gave *sym*-2-phenyl-6-*p*-tolyl-2,3-dihydrotetrazine, m. 259° . **XXVIII.** G. PONZIO. *Ibid* 698–705.—In previous papers P. has given data on the prepn. and properties of a no. of so-called peroxides of glyoxime. A paper by Meisenheimer *et al.* (C. A. 19, 2819) leads P. to published some results on β -phenylglyoxime peroxide (I). 5 g. β -phenylglyoxime (II), m. 180° , was treated with 50 cc. 4 N HNO_3 . After 24 hrs. H_2O was added and I was volatilized with steam to remove it from $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and a little tar. 2.5 g. I, m. 108° , were obtained. It does not react with Ac_2O , PhNH_2 , PhNHNH_2 or concd. H_2SO_4 (in the latter it is dissolved and reprecipitated unchanged on adding H_2O). With hot HNO_3 it gives $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$. In the sealed tube with HCl at 160° it decomps. giving $\text{BzOH} + \text{NH}_3$. With Zn dust + AcOH it gives II. With N_2O_4 in Et_2O it remains unchanged. The results of M. *et al.* and the constitution of I are discussed in some detail E. J. WITZEMANN

Substituted dihydropentazines a new series of cyclic nitrogen compounds. FREDERICK DANIEL CHATTAWAY AND GEORGE DAVID PARKES. *J. Chem. Soc.* 1926, 113–7.— $\text{PhC}(\text{NH}_2)\text{NNHC}_6\text{H}_3\text{Br}_2$ and $\text{HN}(\text{O}_2)$ in cooled soln. or $\text{PhCH.NNHC}_6\text{H}_3\text{Br}_2$, PhNH_2 and EtONa heated at 100° for 15 hrs. give 1-[2,4-dibromophenyl]-4-phenyl-1,2,3,5-tetrazole, m. 127° . The 4-*m*-nitrophenyl compd., m. 215° . $\text{PhCBr.NNHC}_6\text{H}_3\text{Br}_2$ and N_2H_4 in EtOH give ω -hydrazinobenzaldehyde 2,4-dibromophenyldiazone (I), m. 123° , darkens on exposure to light and slowly decomps. in the air; it yields salts with mineral acids, the HCl salt, m. 188° (decomps.), BzH gives the ω -benzylidene deriv., yellow, m. 126° , sol in concd. H_2SO_4 with a brown, changing to a red color; EtOH-KOH gives a yellow color; p -nitrobenzylidene deriv., dark violet by transmitted, dark green by reflected light, m. 194° ; EtOH-KOH gives a deep blue color, fading quickly; concd. H_2SO_4 gives a brown color changing to violet. Hydrazobenzaldehyde 2,4-dibromophenyldiazone, m. 237° , from I and $\text{PhCBr.NNHC}_6\text{H}_3\text{Br}_2$ I and HNO_2 (NaNO_2 and HCl in a freezing mixt.) give 1-[2,4-dibromophenyl]-5-phenyl-1,4-dihydropentazine, $\text{PhC.N.N}(\text{C}_6\text{H}_3\text{Br}_2).\text{N.N.NH}$, m. 172° ; rapidly heated, it decomps. with a puff of black

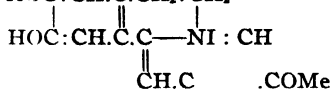

smoke and formation of PhCN ; it exhibits slightly basic properties C. J. WEST

Resolution of *dl*-dicentrine. R. D. HAWORTH, W. M. H. PERKIN, JR. AND JOHN RANKIN. *J. Chem. Soc.* 1926, 29–32; cf. C. A. 20, 206.—*dl*-Dicentrine may be resolved by means of tartaric acid, both the *d* and *l*-forms in 169° and show $[\alpha]_D^{20}$ 61.1° and -63.5° ; direct comparison of the *d*-base with a sample of the natural product establishes the identity of the synthetic product C. J. WEST

Hydroxyacanthine. ERNST SPATH AND ALFRED KOLBE. *Ber.* 58B, 2280–5 (1925).—The results of this work indicate that hydroxyacanthine (I) has the compn. $\text{C}_{40}\text{H}_{40}\text{O}_6\text{N}_2$ and contains 3MeO and 1 phenolic HO group and 2 isoquinoline rings, the other two O atoms are not present as a CH_2O_2 group but probably in ether groupings. The root bark of *Berberis vulgaris* was extd. with EtOH the ext. evapd. to dryness *in vacuo*, treated with hot dil. HCl and filtered, the filtrate pptd. with Na_2CO_3 , the ppt. completely dried *in vacuo* and extd. in a Soxhlet with Et_2O , in which the I slowly dissolves, and the crude I pptd. from hot dil. HCl with NaBr as the HBr salt (yield, 18 g. from 1130 g. fresh dry bark), which was converted through the free I into the sulfate; this was recrystd. several times from hot H_2O and when treated in H_2O with NH_4OH gave an amorphous ppt. of I which could not be recrystd. from alc. but when dissolved in much Et_2O and concd. sepd. on scratching repeatedly or on seeding, in compact crystals, m. $216\text{--}7^\circ$ (all m. ps. in evacuated tubes), mol. wt. in camphor 594–643; di-HCl salt, m. $270\text{--}1^\circ$, $[\alpha]_D^{20}$ 188.5° (H_2O); di-HBr salt, m. $273\text{--}5^\circ$ (gas evolution). If the HCl salt is dissolved in moderately dil. KOH and concd. KOH is then added the amorphous resinous *K* salt seps.; it is easily sol. in pure H_2O and regenerates I with CO_2 . With $\text{MeN}(\text{NO})\text{CO}_2\text{Et}$ and NaOMe in MeOH 4 g. I yields 2 g. of a *Me ether*, resinous mass forming a well-crystd. HCl salt. With MeI and NaOMe in MeOH , 1.2HCl gives a *Me ether dimethiodide*, $\text{C}_{40}\text{H}_{40}\text{O}_6\text{N}_2\text{I}_2$ (II), m. $255\text{--}60^\circ$, 2 g. of which, boiled in dil. NaOH , yields 1.54 g. of an amorphous base which on renewed methylation and boiling with NaOH gives NMe_3 and a hydrocarbon to be studied later. II (11.6 g.) shaken in hot H_2O with excess of AgCl , filtered, heated on the H_2O bath with Na-Hg and extd. with Et_2O , the yellowish viscous mass remaining when the Et_2O is evapd. being then treated in MeOH with an excess of MeI , gives 7.5 g. of a compd. $\text{C}_{40}\text{H}_{40}\text{O}_6\text{N}_2\text{I}_2$, m. $230\text{--}1^\circ$, which on treatment with AgCl and then with Na-Hg yields a compd. $\text{C}_{36}\text{H}_{40}\text{O}_6$, m. $124\text{--}15^\circ$, mol. wt. in camphor 560. C. A. R.

Syntheses of hydroxyberberine, palmatine and tetrahydrojatrorrhizine. ERNST SPATH AND HERBERT QUIETENSKY. *Ber.* 58B, 2267–72 (1925).—Since the supposed synthesis of berberine (I) by Pictet has been shown by Haworth, Perkin and Rankin

(*C. A.* 18, 3385) to have been based on error, the prepn. of palmatine (II) starting from tetrahydroberberine (*C. A.* 16, 1778) can no longer be considered a "synthesis" of II. S. and Q., however, have now really synthesized I through hydroxyberberine (III), which was prepd. about the same time by Perkin, Rây and Robinson (*C. A.* 19, 1710), from whose results those of S. and Q. differ only in minor respects and are, therefore, not reported in detail. A new method for the conversion of I into II has been devised and tetrahydrojatrorrhizine (IV), identical with the product obtained from the natural alkaloid (*C. A.* 20, 603), has been synthesized. When 8 g. I sulfate is heated with H_2SO_4 in the presence of phloroglucinol (V), the CH_2O_2 group is split off as HCHO , which condenses with the V to difficultly sol. products; the filtrate from these is treated with NaI and the pptd. iodides are treated with dil. KOH , which leaves the I iodide undissolved, while acidification of the intensely brown KOH ext. yields 8.1 g. of the yellowish brown iodide $\text{HOC}:\text{CH}:\text{C}:\text{CH}_2:\text{CH}_2$

$\text{CH}:\text{CH}:\text{C}:\text{OME}$, 1 g. of which in 3 cc. MeOH with 0.1 g. Na in 2 cc. MeOH and 0.42 cc. Me_2SO_4 , the same amts. of NaOMe and Me_2SO_4 being added twice more at 3-hr. intervals, gives 0.7 g. II iodide, while 3 g. of the iodide in 20 cc. MeOH with 0.307 g. Na in 6.15 cc. MeOH and 1.28 cc. Me_2SO_4 , the same amt. of NaOMe and Me_2SO_4 being added once more after 4 hrs., gives 1.06 g. of a product which with Zn dust and dil. H_2SO_4 on the H_2O bath gives IV, m. 216–7°. C. A. R.

Action of acetylene tetrabromide on organic bases. J. D. FULTON. *J. Chem. Soc.* 1926, 197–9. $\text{C}_2\text{H}_2\text{Br}_4$ and tert. bases give additive compds. of the HBr with the $\text{C}_2\text{H}_2\text{Br}_4$. H_2O decomp. these compds., liberating the $\text{C}_2\text{H}_2\text{Br}_4$. *Nicotine*, $\text{C}_{10}\text{H}_{14}\text{N}_2 \cdot 2\text{HBr} \cdot 2\text{C}_2\text{H}_2\text{Br}_4$, softens 140°, m. 178–80° (decompn.); $[\alpha]_{\text{D}}^{17} \text{green}$, 3.21° (EtOH , c 5.6025); repeated crystn. gives the compd. $(\text{C}_{10}\text{H}_{14}\text{N}_2 \cdot 2\text{HBr})_2 \cdot \text{C}_2\text{H}_2\text{Br}_4$, m. 182–3° (decompn.); $[\alpha]_{\text{D}}^{17} \text{green}$ 6.96° (EtOH , c 5.6025); both give the same bromoaurate, $\text{C}_{10}\text{H}_{14}\text{N}_2 \cdot 2\text{HBr} \cdot \text{AuBr}_3$, dark red, m. 183°. *Pyridine*, $\text{C}_5\text{H}_5\text{N} \cdot \text{HBr} \cdot \text{C}_2\text{H}_2\text{Br}_4$, m. 108–9°; bromoaurate, brownish red, m. 318–9°. *Quinoline*, $(\text{C}_8\text{H}_7\text{N} \cdot \text{HBr})_2 \cdot \text{C}_2\text{H}_2\text{Br}_4$, softens 115°, m. 136°; bromoaurate, dark red, m. 171–2°. *Isoquinoline* gave mostly its HBr salt, m. 207°; the additive compd., $(\text{C}_8\text{H}_7\text{N} \cdot \text{HBr})_2 \cdot \text{C}_2\text{H}_2\text{Br}_4$, m. 155–6°, was not quite pure. Bromoaurate, dark red, m. 223°. *Lutidine*, $(\text{C}_7\text{H}_9\text{N} \cdot \text{HBr})_2 \cdot \text{C}_2\text{H}_2\text{Br}_4$, m. 135–40°. α -*Picoline*, $\text{C}_8\text{H}_7\text{N} \cdot \text{HBr} \cdot \text{C}_2\text{H}_2\text{Br}_4$, m. 104–5°. *Piperidine*, *coniine*, *homopiperonylamine*, *menthylamine*, *hexamethylenetetramine* and PhNHNH_2 gave rise to the HBr salts only. Antipyrine and pyrrole do not react with $\text{C}_2\text{H}_2\text{Br}_4$. C. J. WEST

The influence of chemical constitution on the odor of mustard oils (DYSON) 11A. The catalytic hydrogenation of organic substances (SCHMIDT) 2. Characteristic reactions induced by light-excited Br (isomerization of diethyl maleate) (EGGERT, *et al.*) 3. Absorption spectra of benzophenone derivatives (TASAKI) 3.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Liver and blood catalase. II. P. RONA, A. FIEGAL and Y. NAKAHARA. *Biochem. Z.* 160, 272–84 (1925); cf. *C. A.* 17, 1034.—Blood or liver catalase, rendered inactive by KCN , was restored to activity by destruction of the KCN with H_2O_2 ; the recovery of catalase action followed at a definite time interval the oxidation of the KCN . SO_4^{--} , Cl^- and NO_3^- ions diminished catalase action in acid soln., p_{H} 3–5, but showed little or no effect on catalase action at a p_{H} 7–8. F. A. CAJORI

The behavior of saponin during dialysis. I. KOFLER and A. WOLKENBERG. *Biochem. Z.* 160, 398–406 (1925).—The time of dialysis of 1% solns. of various saponins through parchment paper was recorded. A certain relationship was found between the speed of dialysis of different saponins and the ease of their absorption from the intestinal tract. Saponins were purified by electrodialysis; this process removed inorg. impurities but did not lessen the hemolyzing power of the saponin. F. A. C.

The action of hydrochloric acid and of pepsin and hydrochloric acid on dissolved proteins. H. W. VAN URK. *Biochem. Z.* **160**, 448-50(1925).—HCl changes egg albumin to acid albumin, which is *l*-rotatory ($[\alpha]_D = -83^\circ$). Pepsin with HCl forms proteoses and peptones which also are *l*-rotatory. The fact that the products of both these agents are *l*-rotatory explains the apparent similarity of the action of gastric juice and acid on proteins. F. A. CAJORI

More on phosphorylation of sugars. C. NEUBERG AND M. KOBEL. *Biochem. Z.* **160**, 464-6(1925); cf. *C. A.* **19**, 3278.—The H_2PO_4 esterification of fructose during fermentation was uninfluenced by the presence of $Na_2Fe_2(P_2O_7)_3$ and it seems unlikely that complex Fe salts play any role in this type of sugar change as it occurs biologically (cf. Spoehr, *C. A.* **18**, 2131). F. A. CAJORI

The preparation and chemistry of insulin. H. A. SHONLE. *J. Chem. Education* **3**, 134-47(1926).—A review with bibliography. E. J. C.

Action of the secretion of the peptic-hydrochloric acid glands on monobutyryl. CARLO COSTANZI AND ANTONUCCI SEVERINI. *Arch. farm. sper.* **40**, 220-34(1925).—Gastric juice collected from a small stomach in the fundus by the Pavlov operation on a dog and tested by the stalagmometric method with monobutyryl showed lipase to be present in some samples and absent from others. When the secretion is obtained entirely free from blood and from cells of the mucosa it contains no lipase even after ingestion of foods rich in fats. The presence of lipase indicates contamination with blood or tissue cells. The enzyme is not secreted by the peptic-HCl glands

A. W. DOX

Further studies on the structure of the proteins. Studies on the physical and chemical properties of the 2,5-diketopiperazines. Comparative studies on the cleavage of 2,5-diketopiperazines at definite p_H without affecting the dipeptide linkage and studies on the behavior of proteins and peptones under the same conditions. Fumaric acid among the cleavage products of gelatin. EMIL ABDERHALDEN AND RICHARD HAAS. *Z. physiol. Chem.* **151**, 114-25(1926).—The presence of diketopiperazines in proteins has already been established beyond doubt. It is possible, however, that in some proteins this grouping occurs in its more labile tautomeric form, and perhaps this difference accounts for the ease with which many proteins are hydrolyzed by enzymes in contrast to the great resistance of proteinoids such as keratin and fibroin. In isolated diketopiperazines the opening of the ring occurs more readily than the further cleavage of the resulting depeptide into its component amino acids. It occurs even at a p_H which is of biol. significance. At p_H 11.40 glycine anhydride, alanyl-glycine anhydride and alanine anhydride undergo partial hydrolysis at room temp. until after 160 hrs. an equil. is reached and the p_H has dropped to 8.50. Silk peptone and casein behave in the same manner, the drop in p_H being accompanied by a rise in CH_2O titer and a diminution in intensity of the picric acid and 3,5-(O_2N) $_2$ C $_6$ H $_3$ CO $_2$ H color reactions. The adsorption by charcoal is about 5 times as great with the anhydrides as with the corresponding dipeptides. Another difference is the fact that the anhydrides are pptd. from alk. soln. by K_2HgI_4 , whereas the dipeptides and amino acids, with the exception of tryptophan and histidine, are not pptd. In this pptn. the Hg^{++} is reduced to Hg^+ . In distg. the amino acid esters obtained by acid hydrolysis of gelatin and esterification with MeOH, 5 g. of methyl fumarate was obtained from 1 kg. of gelatin.

A. W. DOX

Further studies on the structure of the proteins. Comparative oxidation experiments. EMIL ABDERHALDEN AND HANS QUAST. *Z. physiol. Chem.* **151**, 145-50(1926); cf. preceding abstr.—Oxidation of silk peptone by $Zn(MnO_4)_2$ gives both oxamide and (CO $_2$ H) $_2$. The diketopiperazine ring probably is first oxidized to tetraketopiperazine (I) which then undergoes hydrolysis. Attempts to isolate I were, however, unsuccessful. A parallelism was demonstrated between the intensity of the picric acid reaction, the NH_2N present and the yield of oxamide, after preliminary treatment with *N* NaOH followed by oxidation. With prolongation of the alkali treatment the oxamide yield and the picric acid reaction decreased and finally disappeared while the NH_2N increased.

A. W. DOX

Chemistry of the blood pigment. IV. Sulfhemoglobin. Addenda to previous papers. FELIX HAUROWITZ. *Z. physiol. Chem.* **151**, 130-44(1926); cf. *C. A.* **18**, 3065.—Sulfhemoglobin was obtained in cryst. form by alternate treatment of a 20% soln. of Hb with H_2S and O_2 until the absorption bands of Hb had disappeared, and adding 20% of EtOH to the ice-cold soln. The product shows an intense band in the red at $\lambda 617$. When the aq. soln. stands in the air S gradually seps. It was not detd. whether S-Hb contains chemically bound or merely adsorbed S. The Fe is in org. linkage since it cannot be removed by dil. HCl after heat coagulation. The Fe content

(0.34%) is identical with that of pure Hb. The supposed SO-Hb and CO-S-Hb are mixts. which show merely a S-Hb spectrum superimposed on the spectra of Hb, O-Hb, Met-Hb and CO-Hb. Likewise Se-Hb and CO-Se-Hb are impure S-Hb. Other Hb derivs. described in the literature, Cat-Hb, N_2O_5 -Hb, NO-Met-Hb and AsH_3 -Hb, are merely mixts. The various methemoglobins, however, are equilibria of 2 forms of Met-Hb. CO-Hb, NO-Hb, CN-Hb, F-Met-Hb and S-Hb are individual cryst. substances. A. W. Dox

Hydrolysis of polypeptides by enzymes. EMIL ABDERHALDEN. *Z. physiol. Chem.* **151**, 151-4 (1926).—The recent work of Waldschmidt-Leitz on the sepn. and sharp differentiation between trypsin and erepsin throws new light upon the older expts. of Fischer and Abderhalden whereby the acid amide linkage in proteins was established by "tryptic" digestion. A. W. Dox

The oxido-reductase (dehydrogenase) of yeasts. II. HANS V. EULER AND RAGNAR NILSSON. *Z. physiol. Chem.* **151**, 155-64 (1926); cf. *C. A.* **20**, 57.—The time required for decolorization of methylene blue by washed yeast is greatly diminished by addn. of biocatalyst Z, although the latter alone is without action. The Z-prepn. can, therefore, replace the co-reductase removed by washing. Muscle juice activates yeast reductase in the same manner. The ash from the Z-prepn., on the other hand, is inactive. CH_3O is inhibitory and AcH without action. The activity of yeast reductase is increased also by warming to 40° . Reduction of $NaNO_2$ could not be demonstrated. A. W. D.

Supplement to the paper "Biocatalysts of carbohydrate metabolism. III," by Hans v. Euler and Karl Myrback. EMIL ABDERHALDEN. *Z. physiol. Chem.* **151**, 165-6 (1926); cf. *C. A.* **20**, 425.—The slight acceleration of yeast fermentation by insulin was not claimed by A. to be due to the component responsible for hypoglycemia. Certain amines are known to have a similar effect. Moreover, the activity of insulin preps. from various sources, as detd. by animal expts., does not run parallel to the effect on fermentation. A. W. Dox

Influence of chemical constitution on the odor of mustard oils. G. M. DYSON. *Perfumery Essent. Oil Record* **17**, 20-2 (1926).—Several important generalizations have been drawn from a consideration of the effects observed in lengthening and branching of carbon chains, and of the nature and orientation of substituent groups on the odor of alkyl- and substituted arylthiocarbamides. As far as these mustard oils are concerned the odor characteristics are divisible into 3 classes, viz., strength, nature and quality. The strength of odor is due in large measure to volatility. Hence any chem. process which tends to decrease the volatility, such as lengthening of C chains, introduction of NO_2 , SO_3H , CO_2H or OH groups, multiplication of substituent groups, tends at the same time to decrease, and in some cases completely to inhibit, the odor. By nature of odor is meant the class to which the odor of the compd. belongs. Thus, by taking the odor of phenyl mustard oil as the true aromatic mustard oil odor, all substances with a similar, or slightly modified, odor are said to have odors of the same nature. The presence of a single *o*- or *m*-group causes little or no modification in the nature of the odor, while the presence of a single *p*-substituent causes an aniseed-like odor which is almost independent of the chem. nature of the substituent group. Where *o*- and *p*-groups are present together the effect of the *p*-substituent usually predominates, while if 2 *o*- or *m*-, and 1 *p*-group are present the nature of the odor is often entirely different from that of either compd. produced by *o*- or *p*-substitution alone. The quality of the odor is a more subtle distinction than the 2 foregoing properties; it is another term for the delicacy or harshness of the odor. An increase in no. and wt. of the substituent groups usually softens and sweetens the odor, which effect is also obtained in the aliphatic series by lengthening the C chain. Branching the C chain has the opposite effect. The constitutional use of these principles in rational synthesis is obvious. W. O. E

Has air a vital property? F. E. HARTMAN. *J. Am. Soc. Heating Ventilating Eng.* **32**, 67-72 (1926).—The vital property of air is ozone or activated air which contains ozone rather than a negative property attributed to lack of poison. Ozone has been used successfully in treating tuberculosis pertussis and anemia by daily inhalation. It increased the oxyhemoglobin of the blood 1-4%. This ionized oxygen seems to act as a catalyst. It is suggested as the "air-soluble vitamin." H. C. HAMILTON

Normal variations of the inorganic phosphate of blood. R. E. HAVARD AND G. A. REAY. *Biochem. J.* **19**, 882-7 (1925).—The authors used a micro-adaptation of Brigg's modification of the Bell-Doisy technic (*C. A.* **16**, 3493). They noticed a seasonal variation in the av. normal blood phosphate of from 2.9 mg. P per 100 cc. in January to 4.0 mg. P per 100 cc. in August. Rises in the inorg. phosphate of 20-50% during sleep were observed. BENJAMIN HARROW

Binding of iodine. I. Binding of iodine by aromatic substances. A. JEZLER. *Z. ges. expl. Med.* **46**, 486-99(1925).—The power of phenol and of serum to bind I is a function of the p_H . In acid medium the binding of I is adsorptive or physical in character; in alk. medium it is chem. The adsorptive binding of I is dependent on the degree of dispersion of the proteins. When p_H and degree of dispersion remain uniform the power of binding I is influenced by the ions present. HARRIET F. HOLMES

The radiophysiological equilibrium is shifted by *l*-adrenaline to the α side, by *d*-adrenaline to the β side. H. ZWAARDEMAKER. *Verslag Akad. Wetenschappen Amsterdam* **34**, 872-3(1925); cf. *C. A.* **14**, 2497; **15**, 2448. —While *l*-adrenaline shifts the radiophysiol. equil. to the α side, *d*-adrenaline of Meister, Lucius & Brüning was found to have the reverse effect, so that in a certain K-U mixt. and with an adrenaline concn. of 10^{-6} , 25% of the original U-salt content had to be added in order to restore the equil. A considerable error may be involved owing to the possible *l*-adrenaline content of the prepn. MARY JACOBSEN

Further communication on the alleged influence of fructose on blood clotting. E. SLUITER. *Verslag Akad. Wetenschappen Amsterdam* **34**, 949-50(1925); cf. *C. A.* **19**, 3318. —C. p. fructose prep'd. by Kahlbaum from inulin produced no clotting in laked blood. The previously reported effect was due to the presence of 0.64% $MgCl_2$ in com. fructose. While Mg is unable to coagulate oxalated blood, Sr coagulates oxalated, citrated and phosphated blood. The effect is due to the liberation of Ca ions. MARY JACOBSEN

Determinations of permeability in *Saccharomyces cerevisiae* (pressed yeast of the Ned. Gist- en Spiritusfabriek). N. I. SÖHNGEN AND K. T. WIERINGA. *Verslag Akad. Wetenschappen Amsterdam* **34**, 999-1003(1925). —In diffusion expts. the water diffusion and imbibition can be accounted for by adding gelatin to the soln. and detg. the decrease of concn. of both gelatin and the substance exam'd. The method was proved to be reliable by expts. with lactose and NaCl in a 0.5% gelatin soln. The rates of diffusion thus found were: 0.25 mg. NaCl and 3.2 mg. (2.2 mg. in the first, 1.0 in the last 24 hrs.) urea per 48 hrs. and per 1 g. yeast with about 1 sq. m. surface. The water withdrawn from the cell protoplasm in a 1% NaCl soln. is 8%, the imbibition water 12% of the yeast. The latter is 17% for a lactose soln. MARY JACOBSEN

Gas formation in the heart of the cadaver. DVYRENFURTH. *Deut. Z. ges. ger. Med.* **6**, 650-1(1926); cf. Ladislaus Jankovich (*C. A.* **20**, 427). —D. was able to demonstrate gas within 12 hrs. after death. FRANCES KRASNOW

Sulfatase. VII. The splitting of ethereal sulfuric acids of different series by sulfatase and the mechanism of the action of sulfatase. C. NEUBERG AND J. WAGNER. *Biochem. Z.* **161**, 492-505(1925); cf. *C. A.* **19**, 2674. —Sulfatase from fungi is not specific in its action, but hydrolyzes sulfuric acid esters of simple phenols, naphthols, dihydroxybenzenes, substituted phenols, as well as phenolic aldehydes and acids, and quinoline and indole derivs. However, some of the aliphatic or terpene esters such as the ethyl, amyl, mandelic or borneol esters are not hydrolyzed. Either $CaCO_3$ or $BaCO_3$ may be used to control the neutrality of the soln. A water ext. of the enzyme may be filtered clear with practically no loss in activity. W. D. L.

The hormone of the estrual cycle II. E. LAQUEUR, P. C. HART, S. E. DE JONGH AND J. A. WIJSENBECK. *Deut. med. Wochschr.* **52**, 52-5(1926). —A water-clear, protein-free, partly dialyzable aq. soln. has been obtained from ovarian follicle fluid which has the properties of inducing the estrual cycle in mice and is named "menformon." Potent solns. yield residues, upon drying, that are too slight to weigh (0.01-0.1 mg. per "mouse unit"). All protein reactions were negative. No N_2 could be demonstrated by the micro-Kjeldahl method in the purer prepns. NH_3 , OH, P and cholesterol were also absent. Apart from its sp. effect menformon has no toxic action upon the mouse, rabbit or man. There is no depressor action and no effect upon the frog heart nor upon respiration. A definite contraction of the isolated uterus of the virgin guinea pig can be produced by 15 mouse-units. The metabolism of castrated rats is increased. A striking increase in the growth of the female sexual organs can be produced by 8 mouse-units of menformon in mice. LOUIS LEITER

The physical chemistry of the proteins. E. J. COHN. *Physiol. Rev.* **5**, 349-437 (1925). —Review with extensive bibliography. E. R. LONG

The destructive action of acids, alkalis, and enzymes on insulin. H. A. SHONLE AND J. H. WALDO. *J. Biol. Chem.* **66**, 467-74(1925). —"Insulin may be of a true protein structure possessing sp. physiol. activity or it may consist of a chem. complex attached to a protein structure. However, when the protein is broken down into slightly smaller units, either by acid, alkali, or enzyme, the physiol. functioning is lost. In every instance it is observed that the loss of physiol. activity was gradual and occurred simul-

taneously with the gradual hydrolysis of the protein material. In no instance was it possible to recover any of the activity; the change was irreversible." A. P. L.

The histidine and tyrosine content of a number of proteins. M. T. HANKE. *J. Biol. Chem.* **66**, 489-93 (1925).—The histidine and tyrosine content of a number of proteins have been detd. by the method recently described by H. (C. A. **20**, 1093). The mean values obtained for histidine and tyrosine, resp., are as follows: gelatin 0.53, 0.25; casein 2.61, 4.5; cryst. egg albumin 2.3, 2.35; squash-seed globulin 2.26, 3.05; gliadin 2.1, 2.35; hordein 0.98, 2.43; zein 1.25, 3.66; secalin 1.23, 1.37; sativin 0.74, 1.56; sorghumin 0.51, 2.3; sheep fibrin 2.18, 3.3; swine fibrin 2.27, 3.45; cattle fibrin 2.05, 3.5%. The quant. Millon procedure of Fürth and Fisdher for tyrosine (C. A. **19**, 89, 1721) is not reliable, as it is sensitive to slight and uncontrollable variations in the compn. of the final reaction liquid. The values obtained are invariably much lower than those obtained by that method and by the Folin and Denis procedure.

A. P. LOTHROP

An alcohol-soluble protein isolated from polished rice. W. F. HOFFMAN. *J. Biol. Chem.* **66**, 501-4 (1925).—Extn. of 6.5 kg. of com. polished rice meal with hot 70% alc. yielded 7.5 g. (0.12%) of rice prolamine having a % compn., C 55.92, H 6.49, N 16.22, S 1.14 and resembling those of kafir and sorghum in compn. and soly. The N distribution in % of total N detd. by the Van Slyke method is as follows: NH_3 12.45, sol humin 1.68, insol. humin 1.65, arginine 13.21, histidine 6.24, cystine 1.33, lysine 1.73, amino N in filtrate 53.59, nonamino N in filtrate 7.32, total 99.20. It thus does not contain the high % of $\text{NH}_3\text{-N}$, which is typical of prolamines but contains more basic N than any heretofore isolated, only a small amt. of which, however, is lysine, the arginine content is also much higher than that of any known prolamine.

A. P. LOTHROP

Ultra-violet absorption spectra of blood serum and certain amino acids. WILHELM STENSTRÖM and MELVIN REINHARD. *J. Biol. Chem.* **66**, 819-27 (1925).—The absorption band around 2800 Å. U. of blood serum is due to the proteins present and it is mainly the tyrosine and tryptophan constituents of the proteins which are responsible for this band. The absorption band of tyrosine shifts towards longer wave length and its intensity is increased when the soln. is made alk. The absorption of blood serum changes in a similar manner when the p_{H} is reduced below $10^{-12.7}$. A mixt. of tyrosine, tryptophan, phenylalanine, cystine, glycine, leucine and glutamic acid in the proportion indicated by analysis of blood serum (albumin and globulin) gives a curve which agrees qual. with the blood-serum curve taken at the same p_{H} ; there is quant. agreement between the two curves if the concn. of the mixed amino acids is reduced 25%.

A. P. LOTHROP

The apparent dissociation constants of creatine and creatinine. G. S. FADL and ANDREW HUNTER. *J. Biol. Chem.* **67**, 237-44 (1926).—Creatine and creatinine were titrated electrometrically with HCl at 20°. From the results the apparent basic dissociation const. (K'_b) of creatine is calcd. to be 9.6×10^{-12} , that of creatinine 6.3×10^{-10} ; or pK'_b for creatine is 11.02 and for creatinine 9.20.

A. P. LOTHROP

Zymophosphate formation and biochemical sugar conversion. HANS V. RULF and EDWARD BRUNIUS. *Svensk Kem. Tids.* **37**, 301-7 (1925).—Sugar was fermented by yeast and the CO_2 vol. plotted against time. The experimental variable was 0.0-0.06 M $\text{C}_6\text{H}_5\text{OH}$. A single table gives the decrease in inorg. P with the increase in $\text{C}_6\text{H}_5\text{OH}$. Synthesis of org. P is more rapid for cane sugar than for glucose. A. R. ROSE

Colloid chemistry and pharmacology of the keratin substances of the human skin. HELLMUT MENSCHL. *Arch. expul. Path. Pharm.* **110**, 1-45 (1925).—An increase in vol. of some 25 to 30% occurs when nails imbibe water and in this process of swelling the tissue conforms to the rule of acid resistance and alkali susceptibility. Within the p_{H} zone 1 to 11.5 the swelling does not exceed that which takes place in distd. water, but when the p_{H} reaches 12.3 to 13 or above there is a marked increase in swelling. Neither inorg. nor org. acids increase swelling beyond that induced by distd. water. Alkalies (NaOH , KOH in N and $2 N$ concns.) induce a max. swelling and this is followed by a prompt peptization. In $2 N$ alkali the action is more rapid than in N . In the same concns. NH_4OH is not active. $\text{Ca}(\text{OH})_2$ in a satd. soln. has but a slight swelling effect and even after 3 months no peptization has taken place. Hydrosulfide solns. have a very strong swelling effect and after the max. effect has been attained a slow peptization occurs. Aq. suspensions of As_2S_3 and hepar cause no material change within 48 hrs. Detns. on hair involved extension, elasticity and tensile strength. Distd. water causes no evident swelling during a period of 3 weeks. The effect of alkali is very marked ($2 N$ NaOH , KOH); it can be largely removed by washing and causes but little permanent damage. Hyposulfite solns. have quite an opposite effect, causing

no increased extension and leading to a complete loss in tensile strength within about 5 min. NH_3 in a concn. of 2 *N* is less active. For acid (2 *N*) to have any effect it requires exposure for a period of 3 weeks. The effects of acids of the chloroacetic series is related to their chem. constitution, while inorg. acids in a concn. of 2 *N* cause changes after exposure for 3 weeks comparable to those of trichloroacetic acid. HNO_3 is most active. Salicylic acid in a satd. soln. has no effect on the mech. properties of hair. Tanning agents, especially CH_2O (40%), and, to a less degree, pyrogalllic acid make hair brittle, as does a 20% resorcinol soln. A disintegrative effect occurs when hair is placed in an atm. of pure H_2S . In 2 *N* AcOH pieces of epidermis undergo a typical change, a retectolysis, *i. e.*, a swelling and peptization of the rete malpighii. Peptization of the rete malpighii proceeds very quickly in 2 *N* AcOH (complete within 48 hrs.). AcOH swells the albumoses of the horny layer very actively, but does not modify the keratin substances. The occurrence of retectolysis is in part dependent on the mech. properties of the skin. Inorg. acids penetrate the rete malpighii and cause more or less localized areas of swelling in the stratum corneum, while formic, acetic, butyric and lactic acids induce a diffuse swelling. The changes in the albumoses of the cornified material result in alterations in the elastic structure of the skin. With other acids more or less distinctive changes occur. Retectolysis of pieces of skin occurs on both the acid and alk. sides, the behavior of different acids manifesting certain sp. effects. Alkalies in 2 *N* concn. penetrate the rete malpighii quickly, causing swelling and a prompt peptization which is complete. The characteristic feature of the action of alkali is an actual keratolysis. Alkali also causes a marked swelling of the albumoses of the horny layer and the elastic structure of the epidermis is destroyed. NH_4OH in 2 *N* concn. does not cause such a pronounced effect. The effects of alkali are reversible. NaOH and KOH cause perceptible differences in the stretching capacity of the skin; NH_4OH is without effect. Distd. water does not cause the albumoses of the cornified layer to swell. Deprivation of water, as by abs. alc. or formalin, increases the double refraction of the skin. G. H. S.

Ion antagonism in invertase-protein and invertase-lecithin systems. II. A. SCHÜRMEYER. *Arch. ges. Physiol.* (Pflüger's) 210, 755-8(1925); cf. *C. A.* 19, 3303.—Although NaCl and CaCl_2 are antagonistic as regards the inhibitory influence on invertase + globulin and invertase + lecithin on the alk. side of the isoelec. point of globulin and lecithin, on the acid side of the isoelec. point there is neither an ion antagonism nor a pronounced salt inhibition. In its inhibitory activity in an invertase system NaCl is antagonized by Ca, Mg, Ba and La, but not by Co or Ni. G. H. S.

Time relationships between contraction and lactic acid formation in muscle. OTTO MEYERHOF AND L. LOHMANN. *Arch. ges. Physiol.* (Pflüger's) 210, 790-6(1925); cf. *C. A.* 19, 1295.—Additional data, involving the time relationships of lactic acid formation under different conditions of muscular activity, supporting the authors' concept. G. H. S.

Irreciprocal permeability of surviving membranes. ERNST WERTHEIMER. *Arch. ges. Physiol.* (Pflüger's) 211, 255-9(1926); cf. *C. A.* 20, 443.—Evidence is presented showing that contrary to the idea of Bauer the one-directional permeability of membranes is not due to injury to one side of the membrane but is rather a true irreciprocal permeability. G. H. S.

Absorption of potassium iodide by the skin. E. CANALS AND M. GIDON. *J. pharm. chim.* (8) 2, 102-7(1925).—Soln. of KI by itself or mixed with soap soln. does not penetrate the human skin, but if applied in the form of pomade regardless of the excipient used (fats, hydrocarbons or mineral gel, except lanolin), it is absorbed by the skin and appears in the urine. To guard against liberation of I, $\text{Na}_2\text{S}_2\text{O}_3$ was added to all KI mixts. With lanolin, the absorption of KI is feeble; thus the passage of KI into the organism seems to depend on a state of semi-solid emulsion which it forms with the other excipients. S. WALDBOTT

The electrical behavior and the ion permeability of membranes (III) potential of parchment membranes (FUJITA) 2. Application of X-ray methods to the problem of imbibition (KATZ) 2.

TRUMPER, MAX.: *Memoranda of Toxicology*. Philadelphia: P. Blakiston's Son & Co. 230 pp. \$1.50.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

A kinetic method for the investigation of gastric chemistry. II. G. KATSCH AND HEINZ KALK. *Klin. Wochschr.* 4, 2190-3(1925).—A test meal consisting of 0.2

g. caffeine in 300 cc. H_2O is recommended as a gastric stimulant. It has all of the advantages and none of the disadvantages of the alc. test meal of Ehrmann. M. H.

Apparatus for the graphic registration of oxygen consumption and carbon dioxide production. HANS DETHLOFF. *Klin. Wochschr.* 4, 2440-1(1925).—A detailed description.

MILTON HANKE

Spirometer method of studying continuously the gaseous metabolism of man during and after exercise. K. FURUSAWA. *Proc. Roy. Soc. (London)* 99B, 148-54(1926).—The rapidly altering gaseous metabolism of man during and after muscular exercise may be studied continuously by use of a spirometer of large capacity. The gases within the spirometer are kept continuously stirred; the total ventilation is measured every 10 l.; and samples are taken at intervals for analysis. The results are similar to those yielded by other methods, but are obtained with the expenditure of less labor

JOSEPH S. HEPBURN

Contribution to the technic of the study of gaseous metabolism. H. W. KNIPPING. *Z. ges. expil. Med.* 47, 1-3(1925).—Some improvements have been made on the method of studying gaseous metabolism previously described (*C. A.* 19, 2681). The CO_2 is detd. by a pycnometric method with a sensitive aerometer, and both O and CO values can be read quickly.

HARRIET F. HOLMES

The time limit for the chemical detection of elementary phosphorus. C. IPSEN. *Deut. Z. ges. ger. Med.* 6, 481-7(1925).—Diagnosis must be made from the findings in the blood instead of the usual sources: stomach, intestine, liver, kidney, etc. Even after 12 months P has been demonstrated in blood which had been mixed with P from the head of a phosphorus match.

FRANCES KRASNOW

Ultrafiltration of serum. BRUNOLF BRUKNER AND PAUL UHLENBUCK. *Z. Biol.* 83, 586-92(1925).—The speed of ultrafiltration with the Zsigmondy suction filtration app. may be increased by the application of a stirring device. There is such a device, electromagnetically controlled, for pressure ultrafiltration. Application of high pressures the filter greatly. The optimum speed for the ultrafiltration of serum by the suction method is 12 cc. per hr. and for the pressure method 18 cc. per hr. The fractionation of serum proteins by the removal of electrolytes is successful only in very limited amounts

FRANCES KRASNOW

Microchemical method for the determination of brain lipoids. HENRIETTE GORDISSKA. *Biochem. Z.* 159, 379-94(1925).—Brain material (40-60 mg.) is ground, placed on filters and extd. with alc. to remove fat. The paper is then dried according to the method of Bang. The lipid material is extd. with $(CH_3)_2CO$, the extd. mixt. hydrolyzed with NaOH and treated with $K_2Cr_2O_7$ and H_2SO_4 . The whole is then dild. and treated with KI, and the excess I titrated with $Na_2S_2O_3$. From the difference between the amts. of $K_2Cr_2O_7$ and $Na_2S_2O_3$ used, the amt. of lipid is estd. The details for extn. with petroleum ether, EtOH and $(CH_3)_2CO$ are worked out. The cholesterol in the $(CH_3)_2CO$ ext. is detd. by use of the Liebermann reaction. P is detd. colorimetrically.

W. D. L.

Determination of total iodine in organs, blood and urine. R. v. BODÓ. *Biochem. Z.* 161, 401-3(1925); cf. following abstr.—The org. material in which the I is to be detd. is treated with NaOH or KOH and dried. The carbonaceous material is then oxidized by heating with dry KNO_3 , the residue dissolved, neutralized with 50% H_2SO_4 and chlorine water is added to convert the I to IO_3 . The excess Cl is removed by heat and to the cooled soln. are added KI and acid. The I formed is then titrated with $Na_2S_2O_3$.

W. D. L.

The determination of iodides in urine. RICHARD v. BODÓ. *Biochem. Z.* 160, 386-9(1925).—Fifty to sixty cc. 0.1 N $AgNO_3$ are added to 25 cc. of filtered urine after acidifying with N HNO_3 . After 12-24 hrs. standing in the dark, the pptd. $AgCl$ and AgI are filtered off, suspended in 100 cc. H_2O and 1 cc. N HCl and 15 cc. of freshly prepd. Cl H_2O added. The excess Cl is removed by boiling. After cooling, the $AgCl$ is removed by filtering. The filtrate is acidified with 20% H_3PO_4 and 20 drops of 10% KI added. After 10 min., the liberated I is titrated with 0.1 N or 0.01 N $Na_2S_2O_3$.

F. A. CAJORI

A colorimetric method for the determination of the p_H of cerebrospinal fluid. IRVINE MCQUARRIE AND A. T. SHOHL. *J. Biol. Chem.* 66, 367-74(1925); cf. *C. A.* 19, 3503.—An app. is described which permits the collection of the cerebrospinal fluid over Hg without loss of CO_2 and the detn. of the p_H colorimetrically at body temp., 38°. When detd. by this method the fluid has the same p_H , 7.35 to 7.40 \pm 0.02, as blood. Earlier work gave p_H values much too alk., because of loss of CO_2 ; values of p_H 9 to 10 have been reported.

A. P. LOTHROP

The colorimetric determination of phosphorus. C. H. FISKE AND YELLAPRAGADA

SUBBAROW. *J. Biol. Chem.* **66**, 375–400(1925).—In the methods described phosphomolybdic acid is reduced to a blue substance by 1,2,4-aminonaphtholsulfonic acid rather than by hydroquinol as in the Bell and Doisy and Briggs methods. Reduction is complete in 5–10 min., the color is permanent, and most of the substances likely to be present in the analysis of biol. material do not interfere with the reduction unless present in excessive amts. Methods are described in detail for the detn. of inorg. phosphate in urine and blood and of total P and acid-sol. P in blood. The method may be applied with safety to the analysis of any sort of biol. material with proper attention to detail.

A. P. LOTHROP

The determination of gases in blood and other solutions by vacuum extraction and manometric measurement. III. Gasometric determination of methemoglobin. D

1) **VAN SLYKE.** *J. Biol. Chem.* **66**, 409–14(1925).—Nicolux's method (*C. A.* **19**, 1287) for the detn. of methemoglobin has been adapted for use with the manometric blood gas app. The methemoglobin is reduced by an ammoniacal soln. of $\text{Na}_2\text{S}_2\text{O}_4$ to reduced hemoglobin, which is then satd with CO. The methemoglobin is accordingly estd. from the difference in CO-combining capacity before and after treatment with $\text{Na}_2\text{S}_2\text{O}_4$. The CO is detd. by the method of Van Slyke and Neill (*C. A.* **18**, 3615). The possibility of regeneration of methemoglobin is entirely avoided by the use of CO.

A. P. LOTHROP

The quantitative estimation of tyrosine and histidine in protein and a method for estimating tyramine in protein-containing mixtures. M. T. HANKE. *J. Biol. Chem.* **66**, 475–88(1925).—"The complete analytical process is, briefly, as follows: The protein is hydrolyzed with H_2SO_4 . Histidine is pptd. as Ag complex and its amt. estd. colorimetrically (Koessler and Hanke, *C. A.* **13**, 3200). The filtrate from the histidine Ag is boiled with $(\text{AcO})_2\text{Hg}$ and treated with NaCl, which ppts. tyrosino-mercuric chloride, a white solid very insol. in H_2O and in a mixt. of amino acids. This ppt is dissolved in 20% HCl, freed from Hg by H_2S and the tyrosine is estd. in the Hg-free filtrate by the method of Hanke and Koessler (*C. A.* **16**, 1104). A method for estg. tyramine and histamine in protein-contg. matter in a similar manner is also described.

A. P. LOTHROP

A continuous dialysis or extraction apparatus which operates at reduced pressure with a constant volume of liquid. M. T. HANKE AND K. K. KOESSLER. *J. Biol. Chem.* **66**, 495–9(1925).—The liquid vol. is solely dependent upon the size of the app. and so can be controlled at will which is highly desirable when the diffusate is to be analyzed. The dialysis or extrn. can be carried out at any desired temp. The dialyzate is always surrounded by freshly distd. solvent and is agitated constantly, greatly increasing the speed of dialysis. Phenol, toluene or other antiseptics may be used to keep the contents fairly sterile depending upon the nature of the expt. The app. functions automatically and can be operated for days with practically no attention.

A. P. LOTHROP

The relation between colorimetric reading and the true p_{H} of serum or plasma. J. H. AUSTIN, W. C. STADIE AND H. W. ROBINSON. *J. Biol. Chem.* **66**, 505–19(1925).—Under pathol. conditions in man and under normal and exptl. conditions in the dog there is considerable variation in the difference between the colorimetric reading of the $[p_{\text{H}}]$ of dild. serum or plasma at either 20° or 38° and the true p_{H} of the undild. serum or plasma at 38°. A method is outlined of detg. ($[p_{\text{H}}] - p_{\text{H}}$) for making the correction which has checked with ± 0.03 p_{H} the electrometric detns. of the p_{H} 38° of the undild. serum or plasma as drawn in every instance where such a comparison has been made.

A. P. LOTHROP

The determination of calcium in tissues, feces and milk. R. C. CORLEY AND W. DENNIS. *J. Biol. Chem.* **66**, 601–8(1925).—Autoclave digestion of the material in the presence of dil. NaOH soln. is substituted for ashing and the Ca is detd. as usual by pptn. as CaC_2O_4 and titration of $\text{H}_2\text{C}_2\text{O}_4$ with KMnO_4 . Much time and labor are saved and the results are within the limits of reasonable accuracy when compared with those obtained by the ashing process.

A. P. LOTHROP

A method for the determination of the energy values of foods and excreta. F. G. BENEDICT AND E. L. FOX. *J. Biol. Chem.* **66**, 783–99(1925).—"A method has been developed for the indirect detn. of the energy values of foods, feeding stuffs, and excreta. The fundamental principle involves the direct measurement of the O_2 consumed during the combustion of a known wt. of a substance and the computation therefrom of the potential energy of the substance by means of a series of factors for the calorific value of a l. of O_2 previously established with a bomb calorimeter. The app. embodying this principle has been styled the 'oxy-calorimeter.' A brief description is given of the combustion chamber and the device for ignition of the substance, and the adaption of

simple respiration app. as oxy-calorimeters is discussed in detail. Illustrations of the calcn. of results are given, together with tables listing the calorific values of O_2 for some commonly metabolized compds. and for a number of various foods and excreta. This simple form of oxy-calorimeter is recommended especially for hospitals, dietetic labs., and those institutions already possessing one of the numerous simple forms of closed-circuit respiration app. Av. calorific values of O_2 for use in connection with detns. with the oxy-calorimeter are suggested as follows: for N-rich substances 4.68, for fats 4.7, for carbohydrate-rich foods 5.0, for a mixed diet of carbohydrates and fats 4.825, for feces 5.0 cal. per l. of O_2 ." A. P. LOTHROP

The use of the quinhydrone electrode for the determination of the hydron concentration of feces. C. S. ROBINSON. *J. Biol. Chem.* **66**, 811-2(1925).—The quinhydrone electrode of Biilmann may be used for the detn. of fecal reactions and is quite as reliable and much more convenient than the H_2 electrode. The feces are macerated to a thin, homogeneous paste with H_2O and poured into the cell, a little quinhydrone is then added and the cell is shaken to insure uniformity of distribution. The reading is taken at once and the p_H calcd. from Cullen's equation, $p_H = e. m. f. + e_0/0.0001984 T$, e_0 being the e. m. f. of the quinhydrone electrode found by standardizing the system against a soln. of known p_H . A. P. LOTHROP

Standardization of hemoglobinometers by the refractometer. H. C. GRAM. *Acta med. Scand.* **63**, 1-6(1925).—The hemoglobin percentage (Haldane) of a given blood can be detd. by the refractometer by using (1) a 0.8% NaCl soln. (R_1); (2) an 0.8% NaCl soln. contg. 0.14% Merck's purest saponin (R_2); (3) the supernatant fluid from a diln. of 1 cc. blood with 5 cc. of the first soln. (R_3); and (4) the supernatant fluid from a diln. of 1 cc. blood with 5 cc. of the second soln. (R_4). The % of hemoglobin is calcd. from the 4 values of n by the equation $(R_4 - R_3 - k_2)k_1 = \% \text{ hemoglobin}$, where k_2 means $(R_2 - R_1) 5.6/5$ and is a const. for each series in which the same solns. are used. k_1 has been empirically detd. to be 21,500. S. MORGULIS

Method for the determination of bicarbonate in small quantities of serum. J. P. BOUCKAERT. *Compt. rend. soc. biol.* **93**, 841-3(1925).—The titration is carried out on 0.5-1.0 cc. serum to which 0.01 N HCl has been added and the excess titrated back with 0.01 N NaOH to a p_H of 7.4. This is done electrometrically in the Bovie vessel. Better results are obtained on the dialyzate obtained from serum dialyzed against 4 cc. 0.9% NaCl. The titration is carried out in an atm. of H_2 . Another procedure is to titrate against phenol red as indicator, also in the absence of CO_2 , to p_H 7.2 (to correct for the protein error) using a series of standard tubes for comparison. In this case the titration can be made with 0.01 N $Ba(OH)_2$. The $NaHCO_3$ content per cc. serum is 2.20-2.32 cc. 0.01 N. S. MORGULIS

Importance of the protein error in p_H determination with bromothymol blue. D. JAUMAIN. *Compt. rend. soc. biol.* **93**, 860-2(1925).—An error of as much as 0.8 of a p_H may result from a $1/50$ concn. of serum. It is recommended, therefore, to avoid bromothymol blue when the detns. are made with protein-contg. material. S. MORGULIS

Determination of fibrinogen and of fibrin in plasma. EDGARD ZUNZ. *Compt. rend. soc. biol.* **93**, 865-6(1925).—The blood during anaphylactic shock becomes incoagulable and plasma obtained from this blood by long and rapid centrifuging may remain liquid for several days. The plasma is placed in a glass and a current of CO_2 is bubbled gently through it for 20 min. Care must be exercised to avoid as far as possible the formation of foam. This is then left for 4-6 hrs. in an ice box when a fiber clot is formed. Another procedure is to start with citrated plasma, add to it an equal vol. of 1% $CaCl_2$ and then pass CO_2 gas. The clot is gently sepd. from the walls of the glass, pressed into a thin membrane between filter papers until dry, it is then washed 15 min. with H_2O , 5 min. with alc., and 5 min. with ether, and finally dried at 60° first, then at 105° , and weighed. Results are thus obtained agreeing within about 5%. S. MORGULIS

New methods for the determination of cystine. YUZURU OKUDA. *J. Biochem. (Japan)* **5**, 201-15(1925).—Titration of cystine with a bromate soln. in the presence of acid and Br requires only a few min. but cannot be used in the presence of cystine, tyrosine or tryptophan. Titration in a HCl soln. in the presence of I^- with a standard iodate soln. is not as simple as the Br method, but can be used in the presence of all protein cleavage products. It is, therefore, available both as a qual. and a quant. method for detg. cystine in amino acid mixts. Solns. required: 5% aqueous KI; an exact 4% HCl; an exact 2% HCl; a $M/300 KIO_3$ made by dissolving 2.14 g. of pure KIO_3 in 3 l. of exact 2% HCl. The soln. should be standardized against a standard cystine soln. Procedure: To 20 cc. of colorless, exactly 2% HCl soln. contg. 0.005 to 0.05 g. of cystine add 5 cc. of the KI and 4% HCl solns. and titrate with KIO_3 until a faintly

yellow color appears which remains for a min. and read the temp. of the liquid. If this is 17.5° the calcn. is $0.01 \times \text{cc. KIO}_3/4.65 = \text{g. cystine}$, in 20 cc. The amt. of KIO_3 required differs somewhat with the temp. A curve or table showing the relation between temp. and cc. KIO_3 required by the standard cystine soln. can be worked out and used throughout an expt. It was also proved that 6 atoms of Br are required for complete oxidation of a mol. cystine to cystic acid. S. MORGULIS

Subcutaneous injection of gaseous substances such as oxygen. AGASSE-LAFONT AND ROGER DOURIS. *Compt. rend.* 181, 534-5(1925).—A description is given of the technic for the subcutaneous administration of O (cf. following abstract). L. W. R.

Oxygen therapy. The oxygen generator of Agasse-Lafont and Douris for use in oxygen therapy. ROGER DOURIS. *Bull. sci. pharmacol.* 32, 577-85(1925).—Cf. preceding abstract. L. W. RIGGS

Micro-iodometric determination of Cu (SCHOORL, BEGEMANN) 7.

D—BOTANY

B. M. DUGGAR

Chemistry of heterotrophic phanerogams. V. J. ZEILNER. *Monatsh.* 45, 535-8(1925).—The light petroleum ext. (0.89% of the dried material) of *Prosopanche Burmeisteri* de Bary (*Hydnora americana*, R. Br.) contains ceryl alc., phytosterol and palmitic acid. The ethereal ext. (0.31%) contains a resin alc., obtained as a white powder, together with aliphatic acids. The alc. ext. (15.81%) contains a tannin of the protocathechuic acid series, which yields a "tannin red" on hydrolysis with mineral acids, and is converted, when boiled in alc. soln., into phlobaphenes. These form, together with the tannin, more than half of the dried plant material. The tannin is accompanied by sugars and a base which is pptd. by K mercuric iodide. The aq. ext. (26.40%) contains traces of polysaccharides, KCl and probably KH tartrate, the total dissolved mineral matter being 2.42% of the dried material. The latter contained further: free acid 1.69 (as KOH), reducing sugars 1.42, total N 1.49, raw fiber 8.86 and total ash 10.45%. B. C. A.

The proof that acetaldehyde is an intermediary product in the anaerobic respiration of higher plants. C. NEUBERG AND A. GOTTSCHALK. *Biochem. Z.* 160, 256-60(1925).—During fermentation, established under sterile conditions, with the germinating seeds of the sugar pea and bean, CH_3CHO was formed. CH_3CHO is then an intermediary product of anaerobic respiration in higher plants. F. A. CAJORI

The components of the integument of the seeds of *Anagyris foetida*. PIETRO CONDORELLI. *Ann. chim. applicata* 15, 426-31(1925).—The integument, sep'd. by crushing dry, mature seeds, was treated repeatedly with boiling H_2O , filtered, evap'd. to a sirup, pptd. with twice the vol. of 95% EtOH, filtered again and washed with EtOH. The alc. filtrate contained a reducing sugar, which was identified by the method of Fischer (*Ber.* 20, 821; 41, 75) as galactose. No other reducing sugar was present, even in the cotyledons, showing that Reale was in error in reporting the presence of glucose (cf. *Gazz. chim. ital.* 17, 325). The mucilaginous mass was purified by repeated soln. in hot H_2O and pptn. with EtOH until it was white. The term *podalirin* (from the botanical groups) is proposed for this mucilage. It is very sol. in H_2O , not optically active, not pptd. by $(\text{NH}_4)_2\text{SO}_4$ or MgSO_4 and does not give a blue color with I. Oxidation with HNO_3 yields mucic acid. With HCl and phloroglucinol it gives the reaction of a pentose. Hydrolyzed with boiling 4% H_2SO_4 it gives both galactose and arabinose, and heated with HCl it gives furfural. Its properties and reactions suggest para-galactoaraban $(\text{C}_{11}\text{H}_{22}\text{O}_{11}) \cdot \text{C}_6\text{H}_8\text{O}_4$ (cf. Schulze, *Landw. Vers.-Sta.* 41, 207). C. C. DAVIS

The presence of methyl mercaptan in fresh roots of *Raphanus sativus*. L. NOBUZO NAKAMURA. *Biochem. Z.* 164, 31-3(1925).—From 40 kg. of fresh roots 1 g. of pure Hg methylmercaptan, corresponding to 0.31 g. mercaptan, was isolated. It is believed that a large portion of this, if not the entire amt., is present in free condition, though the possibility that the mercaptan is formed from some labile substance during the distn. is not excluded. S. MORGULIS

Influence of light on the alkaloid content of *Lupinus luteus* L. TH. SABALITSCHKA AND C. JUNGERMANN. *Biochem. Z.* 164, 279-87(1925); cf. C. A. 19, 3286.—Elimination of light invariably lowers the abs. alkaloid content of the plant as compared with that of normal plants kept in daylight. Plants germinated in the dark showed later when exposed to daylight a greater production of alkaloid, as well as of total plant substance, than those which have been continuously under the influence of light. The production

of alkaloid took place in the absence of N so that the N necessary for alkaloid synthesis must have been derived from other nitrogenous substances in the plant. S. M.

Effect of anesthesia on the growth of the onion; observations on the anesthesia shock. EDMOND GAIN. *Compt. rend. soc. biol.* **93**, 763-4 (1925).—Anesthesia stimulates growth, which is increased about 168%. But a depression supervenes, which reduces growth to zero with the prolongation of the anesthesia (CHCl_3). When the effect of the CHCl_3 is removed, the plant rapidly awakens and its growth likewise attains a max. in about 15 min.

K—NUTRITION

PHILIP B. HAWK

Feeding experiments on goats with ammonium acetate, urea and horn meal as protein substitutes. K. PAASCH. *Biochem. Z.* **160**, 333-85 (1925).—Detailed data are presented showing the N balance, milk yield and compn. of the milk from goats the protein of whose feed was in part replaced by urea, $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ and horn meal for periods of 2 to 3 weeks in contrast to like periods where no protein substitution was made. Up to 50% of the fodder protein may be replaced by $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ without detriment to milk yield, somewhat less urea, during which feeding, the butter fat yield was lower. Horn meal is a more valuable substitute than either of the others.

F. A. CAJORI

The effect of changes in the sodium chloride and water content of food on the blood and the liquid and salt exchange between tissues and blood. K. ONOHARA. *Biochem. Z.* **160**, 426-32 (1925).—A slight rise in blood NaCl and a fall in total blood solids was found during 3 hrs. after feeding a salt, H_2O and protein-rich diet to dogs. The results indicated that the blood and tissues exchanged H_2O and salts, depending on the quantities of these being eaten.

F. A. CAJORI

A plea for the retention of the term "bios." MARGARET B. MACDONALD. *Science* **63**, 187 (1926).—The suggestion of Funk (*C. A.* **20**, 62) that vitamin D be used is opposed

E. J. C.

A study of some biochemical color tests. III. Color reactions associated with vitamin A. W. R. FEARON. *Biochem. J.* **19**, 888-95 (1925).—About a g. of P_2O_5 is added to 5 cc. of the oil, either undiluted or dissolved in light petroleum, and the tube gently shaken. A deep violet color is obtained if the oil is positive to the Drummond test (dissolve a drop or two of the liver oil in 5 cc. of an anhyd. fat solvent, add a drop of concd. H_2SO_4 , and agitate gently; a violet color, which soon fades, is obtained). The color slowly changes to a muddy brown. The P_2O_5 may be added directly to the oil. The pigment produced with P_2O_5 may be isolated as follows: 50 g. P_2O_5 are rapidly ground up with 50 cc. of an active liver oil. The deep violet color which develops reaches a max. in about 7 min. The mixt. is centrifuged, the supernatant layer poured off, the residue washed with light petroleum and again centrifuged. This is continued until the washings fail to give the Lieberman-Burchard test for sterols. The ppts are suspended in light petroleum, poured into a l. flask $\frac{3}{4}$ full of water, which hydrolyzes the pigment P_2O_5 combination. The pigment is extd. with light petroleum, and the latter evapd. The residue, a pale yellow oil, gives the sterol color tests, but not the Drummond nor the P_2O_5 tests. Pyrogallol may also be employed as a test for vitamin A. One or two drops of the oil, or dry ethereal soln., are placed in a flask, a few crystals of pyrogallol added and then 5 cc. of a 12% trichloroacetic acid in dry light petroleum. The contents are shaken. A blue color slowly develops. This changes to deep rose. Other polyphenols, though not good, or pyrogallol, also give colorations. B. H.

Diet and reproduction. G. GRIJNS. *Verslag Acad. Wetenschappen Amsterdam* **34**, 874-85 (1925); cf. *C. A.* **16**, 3685; **18**, 2189; **19**, 845, 1293.—Of the 2nd generation of rats fed on a diet of corn meal, peanut or coconut meal, meat, hardened fat and salts all females produced young when mated with normal males, while the males were sterile. There was no relation between growth and sterility. Females fed on a diet of corn and peanut meal with 1% cod-liver oil produced larger litters. M. J.

Experiments regarding the dietetics for stomach ailments. A. L. MOLNER AND O. PORGES. *Arch. Verdauungs-krankh.* **36**, 1-28 (1926).—The digestion of fat is facilitated by intimate mixing with amyloses. The latter promote the emulsification of fat and

raise the acidity of the gastric contents. Conversely, the digestion of "Schwartzbrot" is facilitated by the simultaneous digestion of fat. Digestion of cheese is promoted in the presence of "Schwartzbrot," since the optimum acidity is reached earlier. After the ingestion of freshly baked "Schwartzbrot," the stomach contents are coarse and more viscous, the acidity is greater, and the stay in the stomach longer than after the ingestion of stale "Schwartzbrot."

FRANCES KRASNOW

Studies of fat, cholesterol and "steroid" metabolism in the organisms of rats growing in the presence or absence of vitamin A. BACKIANG LIANG AND LEONHARD WACKER. *Biochem. Z.* 164, 371-93(1925).—In the absence of vitamin A growing rats are unable to deposit fat in their bodies even on a carbohydrate-rich diet. The fattening process on a carbohydrate diet is associated with the formation of considerable quantities of endogenous O. It has not been definitely ascertained to what extent vitamin A and lipochrome act as carriers of the O from carbohydrate to other body substances. Pure triglycerides in the absence of vitamin A cannot support life. Likewise, the synthesis of fat from glycerol and fatty acids depends on the presence of vitamin A. Cholesterol is synthesized in the growing organism. This is much more extensive when the diet is poor in fat, cholesterol and vitamin A than in the presence of these substances, and more cholesterol is found in the organism of rats after 5 weeks on the poorer diet than when their diet is rich in fat. The steroid is a substance which the authors have invariably found in conjunction with cholesterol or phytosterol and represents the entire residue of the unsaponifiable portion with the exception of cholesterol. This substance prevents the crystn. of cholesterol and keeps it in colloidal suspension and gives to it a certain plasticity which enables it to form membranes. Under all dietary conditions an excess of steroid substance appears which does not come from the food. Especially much steroid material leaves the body with feces on a fat-rich diet. Whether the steroid is synthesized in the organism could not be detd. The steroid substance increases only slightly in the organism of rats which have been on the exptl. diet for 5 weeks, but when the diet is poor in fat there is no increase at all.

S. MORGULIS

Changes in the tissues and in the organs occurring during hunger. KÄTHE WIRSCH. *Arch. ges. Physiol.* (Pflüger's) 211, 185-212(1926).—In considering the changes occurring in the blood, in wt. and in the tissues during a protracted period of deprivation of food the stage of starvation must be kept in mind as well as individual peculiarities referable to nutritional condition. During a hunger period lasting up to 82 days, involving a loss of wt. equiv. to 59%, dogs showed no distinctive irritation manifestations. Not until late in the hunger period did permanent changes in the compn. of the blood appear. The earlier transient changes in both the water and total N content of the blood were referable to a disturbance in the excretory mechanism. The later permanent blood changes included an increased water content with a reduction in solids, an increase in the total N in proportion to the solids and an increased residual N in proportion to both total N and to solids. Blood sugar remained normal or showed but a slight fall. Acetone and acetoacetic acid never appeared. Quite naturally the abs. wt. of all organs showed a loss during the hunger period, but the relative changes in wt. varied very considerably. Some organs, such as heart, kidney and adrenals, showed an increased relative wt., while in all other organs the change represented a loss of greater or smaller degree, the liver presenting the greatest loss. The chem. compn. of the different organs became modified. With the exception of the spleen the water content of all organs increased; the % of increase was small in some (heart and liver) and considerable in others (pancreas and adrenals). Even after protracted hunger glycogen could still be found in liver and muscle, although the quantities were small (0.02%). The glycogen content of the heart was higher than normal up to the period of exhaustion. During the early stages of hunger the fat content of the liver was extremely high; later this became utilized. Conditions of the kidney approx. those of the liver. The total N content of the liver was increased. In general, during hunger the organs remain functionally normal.

G. H. S.

Vitamin problems. I. Is rickets a combined (B + C) avitaminosis (Reyher)? WALTHER SCHMITT. *Z. Kinderheilk.* 40, 601-19(1925).—There is no clinical evidence that rickets is, in the sense of Reyher, a double avitaminosis (B+C).

ANDREW HUNTER

Oxyproteic acid fraction of urine. E. FREUND AND A. SITTENBERGER-KRAFT. *Biochem. Z.* 157, 261-2(1925).—Reply to Brings (C. A. 19, 1446). B. C. A.

Chemical changes in lipodieresis in the lungs. E. SCHMITZ AND F. PEISER. *Biochem. Z.* 160, 20-7(1925).—No formation of acetoacetic acid (I) or hydroxybutyric acid (II) was found to take place in the surviving cat lungs. During autolysis of lung tissue an increase of II but not of I was found. F. A. CAJORI

The viscosity of human synovia. J. SCHNEIDER. *Biochem. Z.* 160, 325-32(1925).—The viscosity of the synovial fluid obtained at autopsy from 30 hospital cases showed enormous variations, 3.9 to 1490. The viscosity of fluid obtained from 1 case at intervals during an operation varied from 18.2 to 22.2. F. A. CAJORI

Some relations between the reaction and the total ion equilibrium in blood. K. L. GOLLWITZER-MEIER. *Biochem. Z.* 160, 433-41(1925).—Changes in the HCO_3 , Cl, P, Na, K and Ca-ion content of the blood of men, following administration of NaHCO_3 , NH_4Cl and CaCl_2 , overbreathing and CO_2 breathing were studied. The results are discussed from the point of view of exchange of ions between blood and tissues and the effect of such exchanges on the H-ion concn. of the blood. F. A. CAJORI

The question of the existence of combined sugar in the blood. MICHELE BUFANO. *Arch. farm. sper.* 40, 235-50(1925).—The increase in reducing power of blood albumin after the hydrolytic treatment employed for detn. of total sugar in blood is negligible, hence the so-called combined sugar is not due to reducing substances resulting from hydrolysis of protein. Likewise detns. of NH_2N in the plasma from insulinized rabbits before and after the hydrolysis show that no protein hydrolysis has occurred. Furthermore, glycogen subjected to this treatment shows no increase in reducing power. The combined sugar must, therefore, exist in a very unstable combination with the protein without entering into the mol. structure of the latter. A. W. DOX

The chlorine content of the blood (the dependence of the sodium chloride concentration of the blood on the secretion of gastric juice). A. SINDLER. *Z. ges. exptl. Med.* 47, 156-66(1925).—Frequent detns. were made of the NaCl content of the blood of an individual during a period of 9 days, during which the diet was varied. Secretion of gastric juice caused a lowering of NaCl concn. in the blood of 7%. The lowering was most rapid with a meat diet rich in extractives. The addition of 6 g NaCl did not alter markedly the NaCl content of the blood. Hunger is accompanied by a rapid lowering of the NaCl content. HARRIET F. HOLMES

The physiology of synovial fluid. F. A. CAJORI, C. Y. CROUTER AND RALPH PEMBERTON. *Arch. Int. Med.* 37, 92-101(1926).—The concn. of the diffusible constituents of synovial fluid, when uninfluenced by exptl. feeding, closely approaches that of blood plasma. The prompt rise of sugar in the synovial fluid after glucose feeding to the blood sugar level or even higher suggests very easy passage of blood constituents into the fluid and a close connection with the gastro-intestinal tract. Alkalization of the blood by NaHCO_3 feeding and exposure to heat involved no corresponding change in the synovial fluid. MARY JACOBSEN

Carbohydrate metabolism in the animal organism and the presumable origin of glucosurias. CESARE SERONO. *Rass. clin. terap. sci. affini* 24, 253-62; 25, 315-26(1925); cf. C. A. 19, 1902.—Starch is converted by salivary and pancreatic diastase to isomaltose only. This process is most likely completed in the stomach and the isomaltose diffuses directly into the blood. Only a small part of the starch reaches the intestine where it is hydrolyzed by the pancreatic secretion. Intestinal ext. alone produces only a negligible amt. of glucose from isomaltose unless it is activated by salivary or pancreatic diastase. Activation by pancreatic ext. is indispensable for the hydrolysis of glycogen to isomaltose and glucose by liver ext., as well as for the synthesis of glycogen from glucose and isomaltose by spleen ext. Blood from the portal vein contains mainly isomaltose and only traces of glucose, while blood from the hypot-brachial artery contains chiefly glucose. The glucose is oxidized by the cell enzymes mainly to alc. and to a small part to lactic acid. The alc. is easily oxidized by the lungs to CO_2 . This hypothesis could be confirmed in the principle by expts. *in vitro*. Eml-

den's hypothesis regarding the intermediate products of glucose oxidation lacks exptl. support.

MARY JACOBSEN

The influence of hypophysis extract on the stomach. W. SCHOENDUBE AND HEINZ KALK. *Arch. Verdauungs-krankh.* 36, 227-44(1926).—After the injection of the ext. there is, in many cases, a decrease in the gastric secretion lasting about 20 min.

FRANCES KRASNOW

The carbohydrate content of brain. K. TAKAHASHI. *Biochem. Z.* 159, 484-8 (1925); cf. C. A. 19, 1883.—Brain tissue was frozen, ground with quartz sand, treated with 3% NaF soln. (about 6 cc. per 10 g. tissue) and then with 3% $\text{CCl}_3\text{CO}_2\text{H}$ (10 cc. per 10 g. tissue). The mixt. was extd. with H_2O , the filtrate concd., made alk. with KOH and treated with 95% alc. The ppt. was washed with alc. and ether and for quant. detn. inverted by Pflüger's method. The product was identified as glycogen by its reaction with I and KI and by its optical rotation.

The basal metabolism of children. F. B. TALBOT. *Physiol. Rev.* 5, 477-517 (1925).—Review, with extensive bibliography, on normal metabolism and metabolism in malnutrition and a number of other pathol. conditions.

E. R. LONG

The significance of hemoglobin in submammalian forms of life. JOSEPH BARCROFT. *Physiol. Rev.* 5, 596-617(1925).—Review. Hemoglobin acts as an O carrier and, where not transported, as an O store.

E. R. LONG

Red and white muscle. DOROTHY M. NEEDHAM. *Physiol. Rev.* 6, 1-26(1926).—Review. Myoglobin is a pigment closely related to but not identical with hemoglobin. In the white muscle the fibrillary structure may be regarded as a machine adapted to produce rapid motion. A change in H-ion concn. sets this machine in motion, and the breakdown of glycogen through hexaphosphate to lactic acid with combustion of a part of the lactic acid supplies the energy. In the red muscle the same mechanism appears to be present, although not elaborated or used to the same extent.

E. R. L.

The state of the serum calcium in experimental hypo- and hypercalcemia. A. R. MORITZ. *J. Biol. Chem.* 66, 343-51(1925).—In hypocalcemia following thyroparathyroidectomy the decrease in serum Ca shows a disproportionately great decrease of the diffusible fraction. In hypercalcemia produced by injection of parathyroid ext. the ratio of the diffusible to non-diffusible Ca shows no consistent changes. In the former case the original ratio tended to become reestablished with the beginning of the rise of serum Ca in those animals which recovered; the ratio was not restored in the animals which died in tetany.

A. P. LOTHROP

Blood changes during digestion with special reference to urea formation. SERGIUS MORGULIS. *J. Biol. Chem.* 66, 353-65(1925).—During the absorption of protein digestion products there is frequently an increase in the urea N of the systemic blood before there is any increase in amino-acid N; this is shown particularly well in animals tested a short time after breaking a preliminary protracted fast. Not infrequently there has also been observed a fall in the amino-acid N of the blood in the early stages of the digestive process. In 2 dogs with true Eck fistulas the urea concn. of the blood was exceptionally low, 2.9-6.4 mg. per 100 cc., whereas the non-protein N was only a little lower than is generally found in normal animals and the amino-acid N was entirely normal. These findings seem to furnish proof of the urea-forming function of the liver in the intact animal. However "what is generally designated as 'urea formation' may in reality not represent a single process at all. It is not improbable that deamination of the amino acids and the synthesis of urea may be independent processes. The predominant role of the liver may be limited to the process of urea synthesis proper. It is possible that a closer approach towards a soln. of this problem will be attained from this angle."

A. P. LOTHROP

Studies of methemoglobin formation. D. D. VAN SLYKE AND ERIK VOLLMUND. *J. Biol. Chem.* 66, 415-24(1925).—The new method of Van Slyke for the gasometric detn. of methemoglobin (C. A. 20, 1093) has been used in a study of the effect on hemoglobin of certain chem. substances which have been considered to transform it into methemoglobin. When PhNH_2 is absorbed by rabbits it causes anemia without methemoglobinemia and when it acts on blood *in vitro* it does not yield a product which can be detd. as methemoglobin by the $\text{Na}_2\text{S}_2\text{O}_4$ -CO method. PhNH_2 , $\text{K}_3\text{Fe}(\text{CN})_6$ and NaNO_2 in the presence of air convert hemoglobin into methemoglobin. The action of PhNH_2 shows a latent period for some hrs. and after methemoglobin formation has begun it proceeds slowly and several mols. of PhNH_2 are required per mol. of hemoglobin to complete the reaction; this seems to indicate that the product of PhNH_2 rather than PhNH_2 itself causes the methemoglobin formation. Methemoglobin is formed in the cells of unlaked blood by the action of PhNH_2 so that this substance or its product penetrates the cells. NaNO_2 and $\text{K}_3\text{Fe}(\text{CN})_6$ react almost in-

stantly and 1 mol. of each forms approx. 1 mol. of methemoglobin. These substances differ in that NaNO_2 penetrates the cell instantly; methemoglobin formation by $\text{K}_3\text{Fe}(\text{CN})_6$ *in vitro* occurs only after blood is laked as the cells appear entirely impermeable to $[\text{Fe}(\text{CN})_6]$ anions.

A. P. LOTHROP

The chemical investigation of the corpus luteum. IV. The acetone-soluble fat. G. F. CARTLAND AND M. C. HART. *J. Biol. Chem.* **66**, 619-37(1925); cf. *C. A.* **18**, 1178.—Of the acetone-sol. fatty acids in the corpus luteum 52% are present as glycerides and the other 48% as free fatty acids. 35% of the total fatty acids are satd. and 65% unsatd. The fatty acid mixt. has the following % compn.: palmitic 25, stearic 11.2, $\text{C}_{18}\text{H}_{36}\text{O}_2$ 1.6, oleic 32.8, linolic 16.6, arachidonic 8, and 4.8% of a new hexa unsatd. acid which has the formula $\text{C}_{20}\text{H}_{34}\text{O}_2$. 700 g. of the fat, freed from acetone- and alc.-insol. and CdCl_2 -precipitable phosphatides, yielded 524 g. of fatty acids and 105 g. of unsaponifiable material. About 58 g. of cholesterol were crystd. from the unsaponifiable material. **V. The lipoids of the acetone extract.** M. C. HART AND F. W. HEYL. *Ibid* 639-51.—The lipoids present in the acetone ext. of the corpus luteum are cholesterol, cholesteryl palmitate, K stearate, leucine, isoleucine, valine, possibly sphingomyelin, tristearin, a lecithin which was prepd. pure with a N and P ratio of 1:1 and free from contaminating cephalin impurities, and fat, the chemistry of which is given above.

A. P. LOTHROP

The formation of lactic acid by depancreatized dogs. C. J. WEBER, A. P. BRIGGS AND E. A. DOISY. *J. Biol. Chem.* **66**, 653-69(1925).—Depancreatized dogs retain the capacity of forming lactic acid during strychnine convulsions (cf. Sass, *C. A.* **9**, 657) or running. Diabetics thus are able to form lactic acid. These dogs exhibit a remarkable tenacity for the lactic acid precursor substances in muscle; treatment with adrenaline reduces these precursors rapidly to low values.

A. P. LOTHROP

Benzoylated amino acids in the animal organism. I. The behavior of hippuric acid following its oral administration. W. H. GRIFFITH. *J. Biol. Chem.* **66**, 671-81(1925); cf. *C. A.* **18**, 3635. **II. The hydrolysis of hippuric acid in the alimentary canal of the rabbit.** W. H. GRIFFITH AND P. B. CAPEL. *Ibid* 683-90.—"Hippuric acid and benzoylalanine were hydrolyzed in the large intestine of the rabbit, probably by an intracellular histozyme (an amidase which hydrolyzes acyl derivs. of amino acids) present in certain intestinal microorganisms. Benzoyl- α -aminoisobutyric acid, which is not acted upon by histozyme, was not hydrolyzed in the large intestine. Hippuric acid was isolated from the urine of rabbits after the oral administration of benzoylalanine but not after the administration of benzoyl- α -aminoisobutyric acid."

A. P. LOTHROP

The fate of sugar in the animal body. I. The rate of absorption of hexoses and pentoses from the intestinal tract. C. F. CORLI. *J. Biol. Chem.* **66**, 691-715(1925).—Rats were used as the exptl. animal and a known amt. of the substance under investigation was fed by stomach tube. After a given time the rats were killed and the amt. of substance remaining in the whole intestinal tract (stomach, small intestine and the whole large intestine) was quant. detd. after the tract was washed out with successive portions of hot distd. H_2O . For actively growing male and females rats between 100 and 180 g. in wt., the quotient, intestinal surface/body wt., or amt. absorbed/body wt., is a const. "50% solns. of glucose, galactose, fructose and mannose are absorbed from the intestine at a rate which is const. for each sugar. Even after the absorption of 70% of the sugar originally introduced the rate of absorption is not diminished. Hence the rate of absorption of hexoses is independent of the abs. amt. and also of the concn. of sugar present in the intestine. 25, 50 and 80% glucose solns. are absorbed at the same rate, which is considered as additional evidence that the rate of absorption is independent of the sugar concn. present in the intestine. The following order in the rate of absorption has been found: galactose > glucose > fructose > mannose > xylose > arabinose. The selective permeability of the intestinal membrane for stereoisomeric sugars is thus emphasized. Hypertonic sugar soln. is dild. in the stomach by the excretion of H_2O . The H_2O content of the blood, liver and muscle is not changed during the absorption of a hypertonic sugar soln., showing that the vital organs are protected against dehydration, whereas the skin shows a marked diminution in the H_2O content. Glucose, when fed to rats in as large amts. as 15 g. per kg., does not lead to sugar excretion in the urine. With galactose close to 50% of the total amt. absorbed is eliminated in the urine."

A. P. LOTHROP

The excretion of normal sugar urine. N. R. BLATHERWICK, MARION BELL, ELSIE HILL AND M. LOUISA LONG. *J. Biol. Chem.* **66**, 801-10(1925).—Addn. of glucose to a standard diet causes a very small increase in the excretion of fermentable sugar in the urine. There appears to be a significant relationship between the protein of

the food and the nonfermentable sugar as there is an increased % of it as the protein intake is augmented. As daily variations in sugar excretion occur even when the diet is const., it is not possible to conclude from the results obtained without qualification that the nonfermentable sugar is derived from protein metabolism but the expts. strongly point to that as the chief source of this fraction of the normal urine sugar. The chief source of the fermentable sugar is the main carbohydrate metabolism. A. P. L.

The fate of creatine when administered to man. ALFRED CHANUTIN. *J. Biol. Chem.* **67**, 29–41(1926).—There is no evidence of the bacterial destruction of creatine in the alimentary tract and its absorption seems to be complete. There is an increase in creatinine excretion after ingestion of large amts. of creatine and the extra creatinine is derived directly from the ingested creatine. It is suggested that after small doses creatine may possibly be stored and slowly metabolized just as fat or glycogen which has been deposited in their resp. depots. It is possible that stored creatine may act as an anabolite in protein metabolism. A. P. LOTHROP

The question of the interaction of insulin, muscle tissue and glucose. A. D. BARBOUR. *J. Biol. Chem.* **67**, 53–8(1926).—The expts. of Lundsgaard and Holbøll (*C. A.* **19**, 834, 1886, 3520) have been repeated and their results have not been confirmed. "In a series of expts. on mixts. of glucose and insulin in contact with rat, rabbit, dog and guinea-pig muscle, it has been impossible to detect any change in the rotatory or reducing power of the sugar after 2 hrs.' incubation at 37°, or any discrepancy between the concns of sugar obtained by detns. of the rotatory and reducing power. In a mixt. of glucose and insulin alone, it was found to be impossible to detect any change in the rotatory or reducing power of the sugar after 24 hrs.' incubation at 37°." A. P. LOTHROP

Total acid-base equilibrium of plasma in health and disease. I. The concentration of acids and bases in normal plasma. J. P. PETERS, H. A. BULGER, ANNA J. EISENMAN and CARTER LEE. *J. Biol. Chem.* **67**, 141–58(1926).—The total electrolyte equil. of the plasma of healthy individuals under normal conditions has been studied by detg. at the same time the total base, inorg. acids, bicarbonate, chloride, phosphate and protein of the plasma. "The difference between total base and the sum of the base-combining power of the acids enumerated gives a measure of the org. acid and sulfate. The latter is present in negligible amts. only, so the 'undetd.' acid must be practically equiv. to org. acid. Normal serum contains 147 to 161 mM of monovalent base. 138 to 148 millimols (mM) of this base are combined with the 4 acids, protein, bicarbonate, chloride and phosphate. These limits should probably be extended somewhat for hospital patients to 145 to 167 for total base and 135 to 155 for total acid. The org. acid never exceeded 20 mM in normal persons or patients with pathol. conditions in which there was no especial reason to expect a disturbance of electrolyte equil. There is a general tendency for protein, bicarbonate and chloride to reciprocate in their changes and to aid one another in maintaining the total acid and total base at a const. level." II. The effect of carbon dioxide tension on the concentration of the acids of the plasma of oxygenated blood. ANNA J. EISENMAN, H. A. BULGER and J. P. PETERS. *Ibid* 159–64.—

"The sum of the base-combining powers of the acids, $\text{HCO}_3^- + \text{Cl}^- + \text{protein}$ of the plasma of oxygenated blood increases on the av. about 2 mM when the CO_2 tension of the blood is increased from 30 to 60 mm. at 38°. In this change HCO_3^- increases 5 mM. The extent of the increase is detd. chiefly by the concn. of hemoglobin or the vol. of the cells of the blood. The cells swell slightly, diminishing the vol. of the plasma and consequently augmenting the concn. and base-combining power of protein and, to a lesser extent, of phosphate. This is a little more than offset by the diminution of the acid value of protein brought about by reduction of pH . The av. change of plasma vol. amounts to -0.6 vols. %, while the base-combining power of the proteins diminishes about 0.8 mM. Cl^- decreases by about 2 mM, compensating for a little less than $\frac{1}{2}$ of the HCO_3^- change. Because base does not traverse the cell membrane the loss of H_2O from plasma to cells results in a concn. of base that neutralizes the excess acid." III. The differences between arterial and venous blood. J. P. PETERS, H. A. BULGER and ANNA J. EISENMAN. *Ibid* 165–73.—"The general conception that arterial and venous blood differ as regards electrolyte equil. only in so far as they contain more or less CO_2 and O_2 is erroneous. Detns. of O_2 capacity, cell vol., plasma proteins, and the whole blood chlorides show that arterial and venous blood may contain also different amts. of H_2O and chloride. In keeping with this is the fact that CO_2 absorption curves of the 2 bloods may also differ. This explains the fact that attempts to obtain proper respiratory quotients by simple comparison of the differences in O_2 and CO_2 contents of arterial and venous blood have usually failed. The changes that occur while the blood is traversing the tissues affect the sep. components to different

degrees and in different directions; the reasons for these apparent inconsistencies have not, as yet, been detd. The end-result on the plasma acids, $\text{HCO}_3^- + \text{Cl}^-$, of the transformation from arterial to venous blood is an av. alteration of 2.5 mM, usually an increase. The max. changes encountered in 14 examns. of 9 patients, selected because it seemed likely that they would present large venous-arterial differences, were +5 to -2.5 mM." A. P. LOTHROP

Studies on the chemical composition of beef blood. I. The concentration of certain constituents in normal beef plasma. C. S. ROBINSON AND C. F. HUFFMAN. *J. Biol. Chem.* **67**, 245-55(1926).—Analyses of more than 100 samples of blood from normal mature cattle show the following range and av. values, resp., in mg. per 100 cc of plasma: inorg. P 3.0-8.88, 5.87; Cl 294-357, 329; Ca 7.7-14.7, 11.0; CO_2 41.4-75.8, 59.2; K 16.4-41.3, 27.3; Mg 0.31-3.08, 2.16. The max. 24 hr. variations for the first 4 constituents were as follows: 1.87, 24, 2.0, 14.0. Increased intake of Ca phosphate produced a slight increase in the inorg. P and Ca in the blood but the values were still within the normal range. Other factors produced greater changes in these 2 constituents. **II. The composition of the blood of dams and calves immediately after calving.** *Ibid* 257-66.—Certain characteristic changes in the compn. of the blood of cows and calves during the week following calving have been found but in very few cases were values found outside the range for normal cattle. The inorg. phosphate of the blood of cows was approx. 0.64 mM lower than that in calf blood at birth. The values rose slightly during the first few hrs. and at the end of the week were generally higher than those at calving time. The same was true of the calf blood. The Cl content was high at calving and dropped steadily. The calf blood contained less Cl than that of its dam at birth; the amt. increased slightly during the first few hrs. after birth and then dropped though not so consistently as that of the cows. A reduced NaHCO_3 content in both bloods was apparent at birth, the value of the mother being lower than that of her calf and that relationship not being reversed during the 1st week although there was a tendency for both to rise. The Ca was lower in cow blood but tended to increase during the 1st week while the Ca content of the calf's blood decreased. A. P. L.

Studies of intermediary carbohydrate metabolism. XV. Muscle dehydrases. TH. BRUGSCH, H. HORSTERS AND Y. HARADA. *Biochem. Z.* **164**, 271-8(1925); cf. *C. A.* **20**, 941.—On fresh muscle the lactic acid dehydrase has an optimum within 0.1-0.5 M lactate. Muscle deprived of its coenzyme through washing is activated by greater lactic acid concn. (1-2 M). The succinic acid dehydrase has an optimum in low concn. (0.1-1.0 M), is little changed by washing or by high succinic acid concn. Malic acid inhibits the lactic acid dehydrase. It seems probable that the muscle does not produce lactic acid from malic acid by decarboxylation. S. MORGULIS

Systemic and sex determinants of bone growth (*Mus norvegicus albinus*). F. S. HAMMETT. *Biol. Bull. Marine Biol. Lab.* **50**, 61-70(1926).—The systemic and sex factors as determinants of the type and rate of growth of the humerus and femur of the albino rat were studied. The influence of the systemic factors is largely expressed as differences in degree, while that of the sex factors is exhibited as differences in the course as well as in the rate of growth. From the point of view of differential development systemic correlation is closer than sex correlation, both in rate and direction of change, particularly during the period of active differentiation (23 to 65 days of age). From this it is concluded that the sex factors of influence, which apparently are gonadal in immediate origin, are superimposed upon the systemic determinants and direct the sex-sp. course of development. L. W. RIGGS

Influences of constituents of thymus gland cells on growth of young organisms. Y. MIYAGAWA AND K. WADA. *Japan Med. World* **5**, 275(1926); *J. Am. Med. Assoc.* **86**, 231.—When the cell constituents of a calf thymus gland are introduced into the peritoneal cavity of young rats or dogs, the growth, development and differentiation of the animal are influenced. It is believed that there is a direct action of these cell constituents, which are absorbed in the blood circulation, on the cells of living thymus or thyroid, facilitating or retarding functioning, and influencing growth and development. This direct action is only relatively sp., but the stimulus is very adequate and effective. L. W. RIGGS

Methemoglobin formation. VII. Nitrite. ROLF MEIER. *Arch. expil. Path. Pharm.* **110**, 241-64(1926); cf. *C. A.* **20**, 453.—Just as the reaction capacity of nitrate in inorg. reactions is dependent upon the p_{H} , so also is its action on oxyhemoglobin influenced by the p_{H} . In an alk. reaction it causes but very little change, even if present in great excess. In a neutral or in a weakly acid reaction only methemoglobin is formed if there is a definite mol. relationship between nitrite and blood pigment. Below this concn. relationship oxyhemoglobin is present along with the methemoglobin, and above

it both methemoglobin and NO-hemoglobin are present. In a mol. relationship where only methemoglobin is produced about $\frac{1}{4}$ of the O bound to the oxyhemoglobin is liberated, with a corresponding change in nitrite. The reaction may be expressed: $4\text{HbO}_2 + 4\text{HNO}_2 + 2\text{H}_2\text{O} = 4\text{HbOH} + 4\text{HNO}_3 + \text{O}_2$. The NO-hemoglobin appearing in the presence of an excess of nitrite is due to a further breaking down of HNO_2 into nitrite and NO (with a relative deficiency of O) in which the methemoglobin is reduced. In the absence of O methemoglobin and NO-hemoglobin are formed from reduced hemoglobin independently of the reaction. During the acute intoxication of cats with nitrite or nitrous gases a pronounced methemoglobin formation occurs. On standing the blood contains, after some time, only NO-hemoglobin which is due to the fact that the reducing substances of the blood or bacterial O become operative, reacting in the same way as a chem. reducing agent. G. H. S.

Effect of hypophysin and thyreoidin on diuresis. ERNST FREY. *Arch. expil. Path. Pharm.* 110, 329-34(1926).—There is no basis for the concept that hypophysin exerts a colloid chem. effect, it being much more probable that the action is confined to an effect on the vasomotor mechanism. On the contrary thyreoidin has an effect on the colloids: since it causes an infused soln. to pass more quickly from the blood into the tissues with a simultaneous inhibition of the amt. of urine. It also acts in an antagonistic manner as regards the development of edema in the perfusion expt. and at the same time it renders the blood cells more susceptible to hypotonic solns. G. H. S.

Behavior of the constant current in modified nerves. III. Nerves treated with solutions of alkali, acid and the chlorides of zinc, iron and aluminium. D. S. WORONZOW. *Arch. ges. Physiol.* (Pflüger's) 210, 672-88(1925).—Study of the effect of NaOH, HCl, FeCl_3 , AlCl_3 and ZnCl_2 , and of combinations of the salts with acid and alkali upon the cond. of nerves with a const. current showed that NaOH is neutralized by the anode, while the effect of HCl is not completely neutralized by either an- or catelectrotonus. The action of ZnCl_2 is neutralized by catelectrotonus. FeCl_3 induces irreversible changes, as does AlCl_3 , although the latter acts more slowly. When a mixt. of a salt and acid acts upon the nerve the effect induced is that of the more active component of the mixt. Alkali exerts a very potent influence upon the action of salts, favoring the effect of univalent cations, inhibiting the bivalent ones. G. H. S.

Chemical actions of heart-nerve stimulation. LEON ASHER. *Arch. ges. Physiol.* (Pflüger's) 210, 689-96(1925).—Repeated tests in the same expt. with fluids from a period of vagal stimulation and with fluids from a rest period fail to show a const. effect referable to the vagal stimulation. G. H. S.

Physiology of the processes of restoration. I. The submaxillary gland of the dog. N. A. PODKOPAJEW. *Arch. ges. Physiol.* (Pflüger's) 210, 727-35(1925).—By feeding dogs for 1.5 hrs. with zwieback the secretion of the submaxillary gland is exhausted insofar as the sp. components are concerned by about 47 to 48%, but the period of activity of the gland is without influence on the secretion of water and the inorg. components. The process of restoration of the sp. org. substances in the exhausted gland takes place slowly, the normal condition being attained only after 36-40 hrs. G. H. S.

Formation of urine in the frog kidney. VIII. Elimination of sodium chloride and glucose by the undisturbed kidney. A. SCHÜRMEYER. *Arch. ges. Physiol.* (Pflüger's) 210, 759-62(1925).—The question as to whether the kidney allowed to remain *in situ* and perfused behaves like the isolated artificially perfused kidney as regards the concn. of NaCl and glucose is answered, by injection expts. and expts. on pancreatic diabetes animals, in the affirmative. G. H. S.

Nature of the effects on the growth and development of frog larvae due to feeding thymus tissue. E. ABDERHALDEN. *Arch. ges. Physiol.* (Pflüger's) 211, 324-32(1926).—The tadpole expt. is not suited to settle the question whether or not the thymus gland has an internal secretion. G. H. S.

Relation of the thyroid gland to the surface tension of the blood plasma. I. The effect of thyroidectomy. C. M. WILHELMJ AND MOYER S. FLEISHER. *J. Exptl. Med.* 43, 179-93(1926).—Following thyroidectomy in guinea pigs, there is a gradual elevation of the surface tension of the blood plasma which reaches its height in 19-22 days after operation. This elevation is probably permanent, since it has persisted for as long as 120 days. A few animals were found in which the surface tension of the plasma was still within normal limits 24 and 120 days after operation. These exceptions may be due to incomplete thyroidectomy, presence of accessory thyroid tissue or compensatory activity on the part of other organs. The surface tension of the plasma from operated animals is higher than that from controls in both the initial and 20 min. detns., but the difference is greater at the 20 min. period. The time-drop (dif-

ference between the initial and 20 min. detns.) is somewhat greater in the plasma from normal than in that from operated animals. The changes may be due to a decrease in the amt. of certain normally occurring surface-active substances, the production of which is directly or indirectly dependent upon the thyroid gland. **II. The effect of the administration of thyroid extract and thyroxin.** *Ibid* 195-205.—Detns. of the surface tension of blood plasma from guinea pigs, before and after feeding thyroxin, showed in most cases a definite decrease. Out of 27 exptl. animals, 20 showed a depression in the surface tension which ranged from 1.9 to 13.9 dynes (avi, 5 dynes). Six animals showed variations hardly exceeding the limits of exptl. error, while 1 showed an elevation of 1.1 dynes. Six normal control animals bled on the same days, and kept under identical conditions, showed differences in the 2 detns. which ranged from a decrease of 0.5 to an increase of 0.6 of a dyne. One other control showed a drop of 1 dyne. Two animals which had been fed large quantities of thyroid ext. over a period of 10 days gave values considerably below normal. One of these animals survived, and after 11 days during which no thyroxin was given, the surface tension was found again to be within normal limits. C. J. WEST

G—PATHOLOGY

II. GIDEON WELLS

Contribution to the question of intestinal putrefaction with special reference to chronic constipation. JOSEF VON DESCHWANDEN. *Arch. Verdauungs-krankh.* 36, 34-75 (1926)—Intestinal putrefaction after an ordinary meal and after a Schmidt test meal was studied with the aid of a Rodella putrimeter. The investigation indicates that the putrimeter is adapted for measuring the degree of putrefaction—the putrefaction index = mm. Hg \times cc albumin soln. \div hrs. during which putrefaction takes place. In the normal subjects the putrefaction index varies between 120 and 200 with an occasional higher value. In chronic constipation the index is over 300 (Schmidt test meal)

FRANCES KRASNOW

The surface tension of plasma in shock. ZUNZ. *Bull. acad. roy. med. Belg* [5], 5, 334-66(1925).—The surface tension of citrated blood plasma, drawn during anaphylactic shock, is lowered by 5-10 dynes. The same is observed if the shock is produced by electrargol, Witte's peptone, or homologous serum, treated with agar. Atropine, choline-HCl, and hirudin prevent the lowering of the surface tension, the more efficiently the more they prevent anaphylactic shock. The alk. reaction of the plasma is diminished, the more severe the shock; it may even turn acid as far as $pH = 6.9$. The diminution of the alk. is also observed if homologous serum, treated with agar, is injected into rabbits for the first time. R. BEUTNER

Nephrosis and nephritis through cystine. G. O. E. LIGNAC. *Nederland. Tijdschr. Geneeskunde* 69, II, 2203-11(1925).—White mice were injected with a sterile suspension of L-cystine, daily, during 3 weeks (concn. of suspension not given). Retroperitoneal cystine deposits were found, after the animals were killed, also deposits around the capsules of the kidney and spleen. R. BEUTNER

Complement-binding experiments with rabbit serum against bacteriophages and bacterial extracts. P. C. FLU. *Nederland. Tijdschr. Geneeskunde* 69, II, 2285-300 (1925).—The serum of normal rabbits sometimes contains substances which, combined with bacteriophages or with bacterial exts., bind complement. The serum of rabbits, immunized intravenously with bacteriophages, contains antibodies which give complement-binding reactions with all bacteriophages, not only with the special bacteriophage used for immunization. It is impossible to prove by means of complement-binding reactions that all bacteriophages are derived from one original kind. R. BEUTNER

Hypophyseal fat dystrophy with hyperglucemia and glucosuria. Report of a case. S. SHAPIRO AND M. G. KLIATSHCO. *Arch. Neurol. Psychiatry* 15, 85-91(1926).—In a woman aged 32, the basal metabolic rate was -20%, the respiratory quotient 0.86, the glucose tolerance curve resembled that in moderately severe diabetes mellitus, as did the inorg. phosphate. There was no acetonuria, and blood pressure and urine secretion were normal. A. T. CAMERON

Basal metabolism in mental disease. K. M. BOWMAN AND C. C. FRY. *Arch. Neurol. Psychiatry* 14, 819-23(1925).—The literature, and a number of new cases showed tendency towards a low basal metabolism in dementia precox (52 normal, 52 low and 11 high). A. T. CAMERON

Cerebrospinal fluid from different loci. J. B. AYER AND H. C. SOLOMAN. *Arch. Neurol. Psychiatry* 14, 303-14(1925).—This may vary in compn. even in absence of

block. In pathol. cases protein showed marked variation, sugar slight, in samples from different levels.

A. T. CAMERON

The relation between gastric acidity and the hydrogen-ion concentration of the urine with a study of the effect of histamine. F. D. ACKMAN. *Can. Med. Assoc. J.* **15**, 1099-1106(1925).—The degree of urinary acidity in patients with relatively normal gastric acidity appears to vary inversely with the amt. of the latter. In hyperchlorhydria the p_H of the urine throughout the day slowly tends to the alk. side. In achlorhydria the "alkaline tide" is usually wanting. Different diets, as they exert different degrees of stimulus on the gastric secretion, consistently produce corresponding changes in urine p_H . High-carbohydrate and low-protein diets produce little effect. Rich protein diets produce a marked "tide." Starvation tends completely to eliminate the tide, though water be given. Histamine given subcutaneously to an individual having a normal or high gastric acidity increases this secretion and produces a well-marked "tide," and in hypochlorhydria, and in cases of achlorhydria in which histamine stimulates HCl secretion, a "tide" is developed. Where there is no gastric response to histamine no "tide" develops. These results strongly support the theory of the gastric origin of the "alkaline tide," and suggest that where it is impossible to examine the gastric contents directly some conception of the secretory activity of the stomach may be obtained by means of the urine p_H curve based on hourly specimens.

A. T. CAMERON

Serum calcium mirror in pulmonary tuberculosis. G. ROSENSTEIN AND H. SCHMIDTKE. *Beitr. klin. Tuberk.* **59**, 199-203(1924).—The serums of 65 cases of pulmonary tuberculosis were examd. according to deWaard. The Ca values were found reduced, more so as the disease progressed (productive form 10.1 mg.%; productive exudative forms 9.7 mg.%; exudative form 9.1 mg. %). Especially low values were found in cases of combined pulmonary and intestinal tuberculosis. During hemoptysis the serum Ca figures were increased from 0.5 to 1 mg. % . Lime feeding did not increase the figures in pulmonary tuberculosis. On the basis of the examn. of the serum Ca in vagotomy, it is believed that the vagotonic symptoms of tuberculous individuals are attributable to demineralization, especially a diminution of Ca.

H. J. CORPER

Method of preparation of artificial antibodies (antitoxins) for the treatment of diphtheria and tuberculosis. G. A. SMIRNOW. *Beitr. klin. Tuberk.* **59**, 278-99(1924).—Old diphtheria bouillon cultures treated by electrolysis and oxidation proved of therapeutic value in animal expts. It is reasoned that the derivs. produced by the activity of living bacteria on the protein media are responsible for the formation of antitoxin, and not toxins nor other bacterial products. In the animal body the oxidation probably results from the action of cells and their enzymes. Glycerol broth cultures from $\frac{1}{2}$ to 1 yr. old were hydrolyzed 1 to 2 weeks in the incubator with 5% KOH, the tuberculoxins combined with nucleins being pptd. out by concd. H_3PO_4 and filtered. The filtrate is dialyzed through gelatin to remove H_3PO_4 , neutralized and again dialyzed, then electrolyzed 48 hrs., filtered, neutralized and again dialyzed and finally sterilized by filtration. Animal expts. were encouraging and favorable results are reported in lupus and bone and gland tuberculosis as well as first stage pulmonary tuberculosis.

H. J. CORPER

The serodiagnosis of tuberculosis. FRANZ MÜNDEL. *Beitr. klin. Tuberk.* **59**, 622-6(1924).—The Bonacorsi flocculation reaction was positive in 91% of tuberculous individuals, 11.3% non-tuberculous, and 66% lues. Exclusion of the Sachs-Georgi pos. serums increased the specificity of the reaction. Better results were obtained with an antigen consisting of an ext. in alc. of 1% beeswax plus 1% cholesterol in a diln. of 1-10. With this antigen lues serums gave a flocculation in only 10%. Without the addition of the cholesterol to the wax ext. no flocculation occurred, leading to the assumption that the active substance in the Bonacorsi reaction was cholesterol. Pure cholesterol solns. also gave reactions. This clarifies the outcome of the Sachs-Georgi reaction in a large percentage of cases of tuberculosis.

H. J. CORPER

The diagnosis of tuberculosis by means of the flocculation reaction. F. v. KOVATS. *Beitr. klin. Tuberk.* **59**, 645-50(1924).—The serum of children with tuberculosis, lues and in some cases chronic pneumonia give a positive flocculation reaction with $(NH_4)_2SO_4$ (concn. 18-19%). The two latter conditions are easily excluded, thus emphasizing the diagnostic value in tuberculosis. The more intense the tuberculous process the more marked the flocculation with a definite concn. In varying concns. the flocculation parallels the intensity of the disease. A diminution or disappearance indicates a favorable prognosis.

H. J. CORPER

Changes in the surface tension of the plasma and serum. EDGARD ZUNZ. *Ergebnisse Physiol.* **24**, 445-73(1925).—A method for the measurement of the surface

tension of plasma and serum is given, its value in the plasma of guinea pigs, rabbits and man, its lowering in anaphylactic shock, the effect of the intravenous injection of electrargol thereon, and the influence of X-rays. The surface tension of both the plasma and serum in syphilis and other diseases is discussed as well as the advantage of its detn. in plasma over that of serum.

H. J. DEUEL, JR.

Some outstanding physical considerations in radium and Röntgen therapy. D. C. A. BURTS. *Radiology* 6, 47-54(1926).—Cancer is a biophysical and physicochem. alteration in cell metabolism. Malignant cell change is atomic or physical, mol. or chem., and histological. In Ra and X-ray therapy, beneficial results are due to radiations of a negative nature, which reduce the increased potential of neoplastic tissues. The caustic effect of such rays is due to an excess of original or induced electrons in the tissues. By equilibrating quantities of electrons, neoplastic cells may be restored to a normal condition. A résumé is given of the clinical application of these principles in several hundred cases of cancer.

Constitutional serology and its application in biology and medicine. L. HIRSZFELD. *Naturwissenschaften* 13, 17-25(1926).—A review, no bibliography.

B. J. C. VAN DER HOEVEN

The effects of progressive anoxemia on the heart and circulation. JANE SANDS AND A. C. DEGRAFF. *Am. J. Physiol.* 74, 416-35(1925).—Up to the crisis, anoxemia has 2 opposing effects on the heart, the balance of which detn. the systolic discharge: (1) reduction of venous pressure and abbreviation of the phase and the time interval of systolic ejection; (2) rise of pressure in the left ventricle and resulting increase of the rate of ventricular ejection. The result is an increase of the minute flow of blood in the body. With progressing anoxemia (2) always dominates. These effects can be attributed to stimulation of the vagus or of the accelerator mechanism. The crisis which occurs at 9% O is characterized by a reduction of systolic discharge with following reduction of minute output, slowing of the heart and decline of arterial pressure. This effect is undoubtedly due to a direct influence of O deficiency on the heart.

M. J.

The cause of death from anoxemia. A. E. KOEHLER, H. M. F. BEHNEMANN, O. E. BENELL AND A. S. LOEVENHART. *Am. J. Physiol.* 74, 590-615(1925).—In the first stage hyperpnea induces an excessive loss of CO₂ and alkalosis. With the increase of fixed acids because of reduced oxidation in the tissues a normal p_H is established and gives place to extreme acidosis. During recovery the blood p_H returns to normal after a passing alk. as soon as the CO₂ becomes normal. Total CO₂ is reduced to very low limits during anoxemia but does not influence the symptoms. Acidosis plays a role in death since administration of alkali markedly prolongs life. Acidosis interferes with tissue oxidation, and death finally ensues because of failure of the supply of energy required to maintain the physicochemical relationships and the structure of the cell.

MARY JACOBSEN

Flocculation of colloidal gold by proteins. H. A. KREBS. *Biochem. Z.* 159, 311-24(1925).—Only acid Au sols are pptd. by blood serum. Pptn. may occur at 2 ranges of acidity (p_H ranges not given) but with solns. of casein and gelatin only 1 range is noted. The 1st range of pptn. with serum coincides with the isoelec. point of the serum globulin. The albumin is not pptd. with the Au.

Metabolism in pregnancy. V. J. HARDING. *Physiol. Rev.* 5, 279-302(1925).—Review with bibliography.

E. R. LONG

Insulin and phlorhizin diabetes. II. With some further observations on the mechanism of phlorhizin diabetes. T. P. NASH, JR. *J. Biol. Chem.* 66, 889-900(1925); cf. C. A. 18, 708.—"The following results have been observed after giving glucose alone, or with insulin, to fasting phlorhizinized dogs: a diminution in N output in the urine of from 30 to 65% associated with a lowered non-protein N of the blood; little if any effect upon the rate of creatinine excretion; a large decrease in, or complete abolition of, the excretion of inorg. phosphate attended usually by a lowered concn. of blood inorg. phosphates; a large decrease in, or complete abolition of, the ketosis and ketonuria; a pronounced, temporary improvement in the phys. condition of the animals followed by periods of abnormal weakness and prostration; extensive synthesis and storage of glycogen in muscles and liver. No consistent quant. differences in these

results have been noted when equiv. amts. of glucose are given. The av. recovery of glucose when given alone, in 11 expts., was 72.5%. The av. recovery of glucose given with insulin was 72.5%. The effect of glucose retained under the influence of insulin has not been determined. However, glycogen storage has been demonstrated to an extent which supports the possibility of fat synthesis." The elevation of the p_H observed in phlorhizinized dogs following administration of glucose and insulin together may be due to other factors than increased oxidation of glucose, such as the formation of fat or some other reduction product of carbohydrate or the production of lactic acid or some other acid causing hyperpnea and blowing out of "extra" CO_2 . Until these possibilities are eliminated it does not seem justifiable to interpret increases in the respiratory quotient as proof of the oxidation of glucose by the phlorhizinized dog.

A. P. LOTHROP

Total acid-base equilibrium of plasma in health and disease. IV. The effect of stasis, exercise, hyperpnea, and anoxemia; and the causes of tetany. J. P. PETERS, H. A. BULGER, ANNA J. EISENMAN AND CARTER LEE. *J. Biol. Chem.* 67, 175-218 (1926); cf. *C. A.* 20, 1101.—"Prolonged venous obstruction leads to the transfer of H_2O from the blood to the tissues and a concn. of the proteins. Base combined with HCO_3 is unavailable for the neutralization of this excess acid because the usual escape of CO_2 through the lungs is prevented by the presence of the tourniquet. Under these circumstances plasma chloride diminishes, yielding its base to protein and H_2CO_3 . In brief, vigorous exercise considerable lactic acid and an excess of H_2CO_3 are formed, and the p_H of the serum falls. Chloride remains unchanged. Bicarbonate cedes some base to the org. acid but the major portion of the latter is neutralized by base yielded from the tissues. If overventilation is produced as rapidly as possible, symptoms of tetany appear when the p_H has risen by not more than 0.2. Although the total CO_2 of the serum falls, the CO_2 capacity remains unchanged. Org. acid, probably partly ketone acids, but mostly lactic acid, is considerably increased. The total base remains unchanged and the base required for the neutralization of the foreign acids is largely derived from the chlorides, which are diminished. The reaction of the electrolytes to O_2 -want varies according to the respiratory response. If moderate overventilation develops and continues for a long time, bicarbonate falls. The HCO_3 is replaced partly by an increase in the concn. of serum protein, but chiefly by Cl withdrawn from the tissues. If extreme anoxemia is produced org. acid rises and is neutralized by base derived from the tissues. A postencephalitic case presenting overventilation without tetanic symptoms compensated for an extreme reduction of CO_2 by an equiv. increase of Cl. On 3 occasions Cl and HCO_3 were found to have changed, always in reciprocal directions. A malignant hypertension case and one with typhoid fever by vomiting depleted the chlorides of the serum. Under these circumstances tetany followed mild overventilation. The loss of Cl appears to diminish the ability of the organism to prevent tetany by readjusting the acid-base balance after loss of H_2CO_3 . It is suggested that all these reactions are conservative in nature. Any given disturbance of electrolyte equil. will evoke a train of reactions and changes in all the other electrolytes. These reactions always tend to restore equil. The response is not directed towards the maintenance of the concn. of any single constituent or group of constituents, but will be manifested to a greater or less degree in one or the other according as it may best serve to restore the equil. and maintain the functional automatism of the whole organism." **V. Miscellaneous pathological conditions.** *Ibid* 219-27.—"The effects of vomiting on the electrolytes of the serum are highly variable and probably depend on the nature of the vomitus, the severity and duration of emesis, and the degree of inanition produced. The most frequent result is a reduction of Cl, with or without a diminution of base. The level of HCO_3 is capricious. Vomiting of HCl is not essential for the production of this picture, as it has been encountered in a patient with esophageal obstruction who had not vomited. In a series of infections HCO_3 was generally at or a little below the usual level. This may represent the reaction to temp. which reduces the CO_2 capacity of the blood. In lobar pneumonia, on the other hand, HCO_3 is usually normal while Cl is almost invariably low. In some cases diminution of base and in others the presence of an unusual amt. of org. acid are factors in detg. the low serum Cl. These changes are, however, inconst. and therefore cannot be the essential causes of the characteristic hypochloremia. It is tentatively suggested that the reduction of HCO_3 which usually occurs with elevation in temp. may be prevented in pneumonia by the impairment of the respiratory mechanism. CO_2 is, therefore, maintained at a relatively high tension to facilitate escape of CO_2 in the lungs and HCO_3 assumes a larger share of the blood base at the expense of Cl to minimize the re-

duction of p_H that would otherwise occur. Anemia and polycythemia have no characteristic influence on the base or acids of serum." A. P. LOTHROP

Study of renal function in pregnancy. KO YAMADA. *J. Biochem. (Japan)* **5**, 245-85(1925).—Expts. were made with normal, pregnant and puerperal rabbits of about 2.5 kg. in wt. They were given regularly 100 g. "Tofukara," a bean meal, and 50 g. fresh cabbage daily. The urine was taken with a catheter. The creatinine excretion for each individual being very const. the various urinary factors were expressed as ratios over creatinine excretion. Thus, the excretion of NaCl, I, phenol-sulfonaphthalein, lactose, urea, amino acids and NH_3 N was examd. The results of this study indicate that the kidney during pregnancy, when there is a delay in NaCl excretion but not of N substances, cannot be regarded as presenting a condition of tubular lesion, because these symptoms promptly disappear after delivery. Furthermore, although in the pregnant animal on administering NaCl the increased rate of Cl excretion does not begin as promptly nor does it become as high as in normal non-gravid animals, the duration of the increased excretion is not altered. It seems probable that a considerable amt. of the NaCl becomes incorporated in the animal's tissues. The fetus retains more NaCl and H_2O than does the adult organism. The pregnant animal shows the same tendency but to a less degree. The sp. gr. of the urine under a uniform diet shows normal fluctuations, and falls and rises upon the administration of water just as it does in the normal animal. The retention of NaCl and water in the pregnant animal must, therefore, be ascribed to extrarenal factors. Histologically also the kidney during pregnancy reveals nothing exceptional. Further expts. were made with the administration of either Na_2SO_4 or $(NH_4)_2SO_4$ to gravid and non-gravid rabbits for periods of 3-12 weeks. These were given subcutaneously, intramuscularly, intraperitoneally or orally (in several small doses throughout the day). The expts. with the $(NH_4)_2SO_4$ show clearly that an increase in the ammonia content of the blood or tissues causes anomalies in renal excretion which disappear soon when the administration of the salt stops. The amt. of the NH_3 in the blood and tissues always increases during pregnancy and when this exceeds a certain limit cramps occur. This is taken to mean that the cause of anomalies in pregnancy must be looked for in the toxicity of the NH_3 . The increase in NH_3 is ascribed to the overproduction of acids in the pregnant organism, and when Na_2CO_3 is given to counteract the acid the ammon. accumulation is prevented. The abnormal acid formation is attributed to the presence of toxic substances in some pregnant organisms. The anomalies of pregnancy are thus to be ascribed not to a kidney lesion but to a condition of tissue intoxication resulting in overproduction of acids with the secondary effect of bringing about a high NH_3 level. S. MORGULIS

Pentosuria. Report of five cases in one family. H. W. JONES AND C. W. NISSELEK. *Ann. Clin. Med.* **4**, 505-9(1925).—There are 3 types of pentosuria, alimentary, essential and complicating. The cause is not known but it may be due to oxidation of inactive galactose. Pentosuria does not become dextrosuria. JOHN T. MYERS

The Wassermann reaction in serum filtered through collodion sacs. E. TRENTI. *Centr. Bakt. Parasitenk. I Abt., Orig.* **97**, 57-64(1925).—The ability of a serum to fix complement depends on the globulin content. Ultrafiltration of a luetic serum yields a Wassermann-negative filtrate. The residue remains strongly positive and it is more sensitive than whole serum. This has practical value in the control of treatment. JOHN T. MYERS

New colloidal chemical considerations concerning diuresis and some investigations of serum viscosity. ROSINA ISSAKOVA. *Folia Haematol.* **31**, 226-52(1925).—In cases of hypertension, the serum proteins have a high swelling power, which is changed by the addn. of water or electrolytes. This affinity for water may explain high blood pressure. JOHN T. MYERS

No immunity produced by inoculating irradiated tumor tissue. F. C. WOOD AND ROSA E. PRIGOLEN. *J. Cancer Res.* **9**, 287-97(1925).—Expts. with the inoculation of 6000 mice, compared with 30,000 control stock inoculations, furnished considerable evidence against the assumption either that immunity to inoculation, or resistance to a growing mouse or rat tumor, can be induced by the inoculation of radiated tumor material. Initial injection of irradiated tumors did not materially affect the state of resistance to, or susceptibility to subsequent inoculations with the Flexner-Jobling carcinoma, sarcoma No. 10, carcinoma No. 11 or sarcoma No. 180. F. B. SEIBERT

The insulin content of tumor tissue. G. T. CORI. *J. Cancer Research* **9**, 408-10(1925).—Exts. prepd. from malignant and benign tumors, according to the method of Doisy, Somogyi and Shaffer, contain only traces of insulin. F. B. SEIBERT

The relation of certain endocrines to the salt content of rat blood. G. L. ROH-

DENBURG AND O. F. KREHBIEL. *J. Cancer Research* 9, 422-4(1925).—An increased hypermineralization (K, Ca, Na) of the blood to the extent of about 35% is caused by an incised wound, 45% by splenectomy, and 67% by thymectomy, with about the same changes in the relative amts. of K, Ca and Na. Thyroidectomy caused a hypermineralization of 110% with the Na 13% greater and K 13% less than that in normals. Castration caused an increase of 177% with the Na 18% above that in control rats. Adrenalectomy caused an increase of 203% with the relative amt. of K decreased to 9.5%. F. B. SEIBERT

Two cases of cystinuria in children. J. F. H. STALLMAN. *Lancet* 1925, II, 375-8.—Cystine calculi were present. F. B. S.

The experimental treatment of implanted malignant tumors of the rat. T. LUMSDEN. *Lancet* 1925, II, 539-43.—An antiserum to the mouse carcinoma (M. 63) or Jensen's rat sarcoma produced by numerous peritoneal injections of the respective finely divided tumor kills cancer or sarcoma cells *in vitro* rapidly and invariably. It is much less toxic to the normal tissues than to the malignant cells. Pieces of cancer tissue kept in antiserum for 3-6 days at 37° do not thereafter produce a progressive tumor when inoculated into the living animal. Jensen's rat sarcoma of the foot can be caused to disappear by repeated injections of antiserum into and around the tumors, along with temporary stoppage of circulation in the foot. After such a removal of a tumor the rat becomes immune and very often a tumor on the other foot is simultaneously absorbed. F. B. SEIBERT

A case of renal glucosuria with ketonuria. J. PATTERSON. *Lancet* 1925, II, 596-97. F. B. SEIBERT

A clinical study of diabetic coma. W. W. PAYNE AND E. P. POULTON. *Lancet* 1925, II, 638-42.—A report of 11 cases with blood and urine analyses. F. B. S.

Nature of urinary protein. A. HYND. *Lancet* 1925, II, 910-5.—The protein excreted in the urine in various conditions is not always identical. In the 12 cases investigated of "albuminuria of pregnancy" without convulsions the specific rotation of the urinary albumin averaged -55.81° , and thus agreed with that found for human serum albumin under similar treatment, -54.47° . A similar close agreement in specific rotation, -54.27° , was found in five cases of proteinuria not associated with pregnancy. On the other hand, the 14 cases of eclampsia investigated were sharply divided into two groups, one group of six having an av. $[\alpha]_D$ of -56.37° , and the other group of eight having an av. $[\alpha]_D$ of -38.5° . The optical activity of the albumin in the former group agrees well with that of serum albumin (-54.47°), while that in the latter approximates closely to that of cow lactalbumin (-41.17°). Accordingly, it is suggested (a) that in certain types of eclampsia the urinary albumin may be mainly lactalbumin; (b) that eclampsia may be an anaphylactic reaction due to the circulation in the blood of this foreign protein; and (c) that the mammary gland may be an important factor in the causation of eclampsia. F. B. SEIBERT

The behavior of the diabetic toward circulating glucose. H. S. PEMBERTON AND I. CUNNINGHAM. *Lancet* 1925, II, 1222.—The diabetic differs from the non-diabetic in his behavior towards circulating glucose, as follows: (1) during fasting and without insulin, the arterial value differs widely from the venous, sometimes lower and sometimes higher; (2) with glucose and ether and without insulin, there is a greater increase in both arterial and venous values in the diabetic and in the fasting state the venous value may rise higher than the arterial; (3) with insulin, either fasting or with food, the relationship between arterial and venous tends to approach those of the non-diabetic. F. B. S.

The oxygen deficiency theory and experimental tetany. J. A. CAMPBELL. *Lancet* 1926, I, 72-4.—The expts. support the O_2 deficiency theory of Morris in the etiology of tetany. In many different exptl. conditions in which tetany eventually occurs, the tissue O_2 -tension is markedly decreased before the onset of the tremors. Muscular contraction causes a marked increase of O_2 -tension in the tissues and it is suggested that the purpose of the muscular contraction in tremors and convulsions is to supply O_2 at increased tension in the tissues. F. B. SEIBERT

New knowledge of the metabolism of carcinoma cells. A. LASNITZKI. *Z. Krebsforschung* 22, 531-5(1925).—Strips of Flexner-Jobling rat carcinoma put into Ringer soln. contg. dextrose have a glycolytic power 120 times greater than that of blood, 200 times greater than resting and 8 times greater than the maximal working fresh muscle. The glycolytic power lasts for days if the Ringer soln. containing sugar is aerated with O_2 . Glucolysis is checked by narcotics just as is fermentation in the yeast cell. It is only slightly sensitive to HCN. Under aerobic conditions the amt. of glucolysis falls to about 23% of the amt. under anaerobic conditions. Similar results were

obtained with the Jensen rat sarcoma and the Rous hen sarcoma. The anaerobic glucolysis of tumors is nothing more than the anaerobic metabolic phase of embryo tissue. Glucolysis in germinal epithelium, thymus and lymph glands is less than for embryonal tissue. The glucolysis of thymus completely disappears in the presence of O but that of germinal epithelium and lymph adenoid tissue only diminish. There is a question as to whether results *in vivo* are the same as these results where glucolysis was followed *in vitro*. When dextrose was injected intraperitoneally, the glucose as well as lactic acid content of the tumor rose but the lactic acid content of the liver remained the same. In a series of expts. there was an unmistakable antagonism between glucolytic and lipolytic power of the tissues. This is especially true if carcinoma tissue, spleen and skeletal muscle are contrasted with liver and kidney tissue.

F. B. SEIBERT

Isolation of methylated guanidines from the urine in two cases of parathyreoprival tetany. JOACHIM KÜHNAU. *Arch. expil. Path. Pharm.* 110, 76-88(1925).—The amts. found were 51 to 184 mg., as contrasted with normal values of between 2 and 15 mg.

G. H. S.

Metabolism of the liver in chloroform and phosphorus poisoning. RUDOLF HÜTHLE. *Arch. expil. Path. Pharm.* 110, 153-73(1925).—Comparison of the behavior of the liver of the normal rat with the liver tissues of rats subjected to CHCl_3 or P poisoning showed that while the livers of the normal animal would break down from 39 to 42% of the introduced acetoacetic acid within a period of 90 min., in P intoxication the ability to accomplish a breaking down of acetoacetic acid is impaired to such an extent that there may even be more acetoacetic acid present than was artificially introduced. In CHCl_3 poisoning the ability to break down acetoacetic acid is not completely suppressed, as indicated by the fact that in but 1 of 4 cases the damage to the liver was so severe that an increase in acetoacetic acid occurred. Marked changes in the hydroxybutyric-acetoacetic acid reaction occur in CHCl_3 and in P poisoning. The normal rat liver transformed hydroxybutyric acid into acetoacetic acid with such rapidity that under the conditions imposed by the expt. the acetoacetic acid formation represented 30-38% of the hydroxybutyric acid decrease, while in animals poisoned with CHCl_3 and P the abs. amt. of hydroxybutyric acid transformed was within the normal limits of the normal liver.

G. H. S.

Metabolism in lead poisoning. Nitrogen metabolism. A. TSCHERKESS. *Arch. expil. Path. Pharm.* 110, 174-97(1925).—The N, or rather, the protein metabolism in exptl. Pb poisoning presents abnormalities of both a quant. and qual. nature. The intensity and character of these changes depend primarily on the amt. of Pb introduced and circulating in the body. Poisoning with large doses causes a toxic (not specific) increase in protein transformation. The slow effect of small doses, as in chronic poisoning, causes a change that may be divided into 2 stages. First there is an increase in N metabolism associated with the intake of Pb and the reaction of the cell substance to the foreign poison. At this time the amt. of protein decompn. products in the urine is augmented, a N deficit occurs in the body, the appetite fails and the food intake is diminished. When the second stage intervenes the progressive loss in wt. ceases and all life processes become retarded. The amts. of N found in the urine and in the blood indicate that protein decompn. is reduced as is also N utilization. Disturbances in the processes of protein metabolism are revealed by derangements in the coeffs. of the relations of N of the urine; the creatinine-creatinine ratio to total-N is disturbed; the amt. of ammonia N is increased; the p_H of the urine tends to the acid side; and at times a creatinuria manifests itself. This second stage may persist for a month or more in rabbits, and end shortly before death in a renewed transitory increase of metabolism. From the point of view of the pathology of the chronic condition the reduction in metabolic processes in the second stage is most important. A formation within the body of decompn. products of increased acidity is associated with the retarded metabolism and the reduction in processes of oxidation. It is also probable that in a gradual and continued Pb poisoning, with the establishment of a Pb balance in the body, the functional stimulation due to minimal amts. of the poison leads to a diminished fermentative activity and a reduction in the oxidation processes, inducing thereby a retardation of N metabolism. During this period the body stabilizes itself to a new level of physiol. equil. Chronic intoxication in man apparently represents a sp. dynamic action of Pb on the biochem. processes of the body.

G. H. S.

Trypan blue anemia in rabbits and frogs. M. A. PIWOWAROFF. *Arch. expil. Path. Pharm.* 110, 281-94(1926).—Frogs which receive several subcutaneous injections of trypan blue usually present an oligocythemia which may become very marked. Other substances such as *Bact. ranicida*, Congo red, indulin, and neutral red fail to show

a comparable effect. Ink causes only a slight reduction in the erythrocyte count. Trypan blue also causes an oligocythemia in rabbits; apparently the reticulo-endothelial app. plays a role in the anemia.

G. H. S.

Biological action of Röntgen rays. III. Analysis of sensitization to Röntgen rays by thorium salts. PH. ELLINGER AND OSKAR GANS. *Arch. expl. Path. Pharm.* 110, 295-9(1926).—The changes of chem. or colloid-chem. nature taking place in tissues through the action of active protein-pptg. agents are not of sufficient magnitude to explain the increased susceptibility to irradiation; thus it must be assumed that the changed susceptibility following Th is a result of an increased electron emission.

G. H. S.

Protein therapy and its effect on the body in children and experimental animals. A. F. TUR. *Z. Kinderheilk.* 40, 322-30(1925).—In children beneficial results from protein therapy are the exception. The best results are obtained in the treatment of hypertrophic conditions. The clinical effects, the temp. and leucocyte reactions, as well as the changes in the activity of the enzymes of the cells, vary. The increase in temp. sometimes observed after an injection of milk cannot be explained as an effect of bacterial toxins, but is more probably a reaction of the body to the introduced protein. In cases in which protein therapy is beneficial, the effect appears after 1-2 injections. The general condition of the child improves, the wt. increases, food is tolerated better, and the digestive disturbances disappear. In certain cases there is a definite blood rejuvenation due to an increased activity of the blood-forming organs. Neither during treatment nor subsequently does non-sp. protein therapy modify the hemoglobin content of the red cells or the color index of the blood. Arneith's formula usually shifts to the left. Young forms of both red and white cells appear. In cases which are improved by protein therapy the catalase, lipase, esterase, the autolytic serum enzymes, the pepsin of the urine and the autolysis of organs (in exptl. animals) are increased. Amylase and antitrypsin show no consistent changes. In cases which show no improvement the catalase, lipase, esterase and the peptic activity of the urine are diminished. The autolysis of the serum is increased. In clinically indifferent cases the enzyme changes are irregular.

G. H. S.

Periodic fluctuations in fermentative energy in the urine in year old, healthy children and in those suffering from different nutritional disturbances, and the relation of these fluctuations to different digestive phases. A. F. TUR. *Z. Kinderheilk.* 40, 331-42(1925).—Amylase and propepsin are present in the urine of infants. In children during the first year of life the fermentative activity is weaker than in older children, since with age the amt. of enzyme in the urine increases, and at 10-12 years it is essentially that of adults. Only by a repeated, systematic study of fresh urine can a true picture of the state of the intracellular fermentative energy be obtained.

G. H. S.

Goiter in childhood. III. Gas and iodine metabolism in goiter at puberty. A. ECKSTEIN AND E. MOMMER. *Z. Kinderheilk.* 40, 475-87(1925).—Children with goiter show a perfectly normal gas metabolism, indicating that goiter at puberty is not a hyperthyroid condition. It further appears that the administration of I in either large or small amts. fails to modify the gas metabolism in the characteristic way. There is no considerable retention of I. **IV. Iodine resorption in the thyroid.** A. ECKSTEIN AND MARIA NUELLE. *Ibid* 488-92.—The administration of I *per os* to dogs results in a slight deposition of I in the thyroid. Under normal conditions the I content of the thyroid is independent of the wt. of the gland and to a certain degree unrelated to its anatomical structure. Incidentally, in the normal animal the I content of the two halves of the thyroid may not be the same, the result being that factors other than simply an increased I value must be considered in interpreting data observed. In dogs, as in man, the amt. of I retained in the body after the administration of I is extremely small. The effect of I on the thyroid can only be that of a catalytic agent.

G. H. S.

Allergic irritability. III. The influence of chronic infections and of trypan blue on the formation of specific antibodies. P. A. LEWIS AND DOROTHY LOOMIS. *J. Exptl. Med.* 43, 263-73(1926).—The allergic irritability of the guinea pig (capacity of the animal to react to antigenic substances) is increased by infection with *Bacillus abortus* and a streptococcus, by the dead tubercle bacillus and by intensive treatment with trypan blue, resp.

C. J. WEST

H—PHARMACOLOGY

ALFRED N. RICHARDS

The effect of ephedrine on experimental shock and hemorrhage. K. K. CHEN. *Proc. Soc. Exptl. Biol. Med.* 22, 203-6(1924).—In dogs, the low blood pressure of hist-

amine or Witte peptone injections, of surgical, of traumatic and of anaphylactic shock was quickly restored by the intravenous injection of ephedrine, an alkaloid obtained from *ma huang*. An efficient dose was 2.3 mg. per kg. of body wt. The rise and maintenance of blood pressure is attributed to cardiac stimulation. Excessive bleeding or prolonged low blood pressure required transfusion to restore the blood pressure. The use of ephedrine is advocated in surgical shock and hemorrhage and as a prophylactic remedy in long operations. C. V. B.

Histological investigations on organs of rabbits after prolonged treatment with subcutaneous injections of small doses of glycerol. ANTONIO PIRAS. *Arch. farm. sper.* **40**, 251-6(1925).—Prolonged treatment of rabbits by small subcutaneous injections of glycerol produces serious lesions of the liver, kidney and intestine.

A. W. DOX

Animal poisons. HANS DIETMANN. *Pharm. Presse* **31**, 4-7, 22-3(1926).—An enumeration and brief discussion of the more important poisons of animal origin, notably those of certain snakes, toads, salamanders, lizards, scorpions, fish, spiders, myriapods, caterpillars, ants, bees, wasps, flies, etc., with some references to antidotal treatment.

W. O. E.

Tolerance to coramine. KONRAD SCHUBEL. *Klin. Wochschr.* **4**, 2245-6(1925).—Frogs, rats, mice, guinea pigs, rabbits, dogs, cats and apes do not acquire a tolerance to coramine (*N,N*-diethylnicotinamide). The same dose is equally effective regardless of the number of times it has been administered.

MILTON HANKE

The action of theophylline on the tissue. A. FROHLICH AND E. ZAK. *Klin. Wochschr.* **4**, 2305(1925).—The subcutaneous absorption of easily diffusible substances such as NaCl, KI and $K_4Fe(CN)_6$ is enhanced, in frogs and mice, by treatment with theophylline. The absorption of difficultly diffusible substances such as indigo carmine and trypan blue is retarded. The intraperitoneal absorption of any of these substances is enhanced by theophylline.

MILTON HANKE

Detoxication of thallium. A. BUSCHKE AND BRUNO PEISER. *Klin. Wochschr.* **4**, 2444-5(1925).—Thallium, administered as acetate, appears to have a specific action upon the endocrine organs because it leads to changes in the stomach and the bones, affects growth and development and leads to cataract formation. It is highly toxic. Tervalent Tl in the form of dimethyl-, diethyl- or dipropylthallium bromide is only 10% as toxic as TlOAc and has none of the characteristic pharmacol. properties of univalent Tl. The pos. radical $TlMe_2$ is probably very stable and is not decomposed in the animal organism, into the toxic Tl^+ .

MILTON HANKE

Oligodynamic action of a silver preparation. A. E. RUETE. *Klin. Wochschr.* **4**, 2499-500(1925).—The silver prepn. is a very fine powder that contains 95% Ag and 1% Au. Suspended in 1000 or less parts of water, it is powerfully bactericidal to staphylococci. The microorganisms remain intact; but they are dead. The silver can, apparently, be recovered unchanged; it is equally effective when used a second time. The method is recommended for the sterilization of vaccines. Water that has stood in contact with the metal for 24-48 hrs. acquires some bactericidal properties. It is not, however, as effective as the H_2O -metal mixt.

MILTON HANKE

The relation between the regulation of warmth and sugar metabolism. The effect on blood sugar of antipyretics of the pyrazolone group. H. CHIARI AND R. RIGLFF. *Z. ges. expil. Med.* **46**, 433-53(1925).—Pyramidone in small doses intravenously or *per os* causes a lowering of the sugar content of the blood in both man and animals, and in larger doses a marked increase in blood sugar content. In mild cases of diabetes small doses produce a lowering and in severe cases of diabetes a rise in blood sugar content. Dogs after pancreatectomy show an increase in blood sugar after small doses, indicating that the mechanism of the action of pyramidone in lowering the blood sugar content is dependent on the pancreas.

HARRIET F. HOLMES

Experimental alteration of the indirect galvanic irritability of muscle. H. BEHRENDT AND R. HOPMANN. *Z. ges. expil. Med.* **46**, 564-72(1925).—In healthy children and adults a change of metabolism in the direction of alky. caused increased indirect elec. irritability of the muscles. This change of metabolism was brought about by oral doses of $NaHCO_3$ or subcutaneous injection of thymoglandol, pituglandol and insulin. Acidosis produced by oral doses of NH_4Cl caused a decrease in muscular irritability. Testiglandol and epiglandol, which have been reported to cause acidosis, were without effect on muscular irritability. A pharmacodynamic influence on the neuromuscular app. through the vegetative nervous system by means of pilocarpine, adrenaline and atropine was seldom shown and then only in slight degree. H. F. H.

The fundamental characteristics of heart muscle and their mutual relations. VI. F. SCHELLONG AND F. TIEMANN. *Z. ges. expil. Med.* **46**, 703-17(1925).—The heart

muscle of the frog shows max. irritability in the Ca:K ratio of Ringer soln. Addition of CaCl_2 reduces slightly the irritability of normal heart muscle and increases the irritability of injured heart muscle.

HARRIET F. HOLMES

The action of the calcium ion on the sensibility of the vegetative nervous system. ISTVAN WEISS AND Z. BENKOVICS. *Z. ges. expil. Med.* **46**, 784-8(1925).— CaCl_2 given intravenously reduces the sensibility of the vegetative nervous system to adrenaline as long as an excess of Ca is present in the blood. This action may be due to the Ca ion itself or to the action of the Ca ion on the p_H of the blood.

HARRIET F. HOLMES

The action of halogen substitution products of barbituric acid. R. HÜRTLE. *Z. ges. expil. Med.* **47**, 129-40(1925).—Various halogen substitution products of barbituric acid were studied for their pharmacol. effect, but only dibromobarbituric acid was found to have an effect. An abrupt fall of temp. was noted in rabbits and a narcotic effect in dogs. Dibromobarbituric acid was found accumulated in the medulla oblongata in rabbits and in the brain in dogs. The instability of dibromobarbituric acid would probably prevent its therapeutic use as an antipyretic.

HARRIET F. HOLMES

A contribution to anabolic therapy. I. Experimentation with Helypin. J. MAGAT. *Z. ges. expil. Med.* **47**, 211-21(1925).—Helypin, an emulsion of lecithin and glycerol, to which has been added a suitably balanced system of electrolytes, CaCl_2 , KCl, NaCl and NaHCO_3 , on intramuscular or intravenous injection increases the physico-chem. activity of the cells, activating the synthetic processes of the cell.

H. F. H.

The influence of insulin, administered orally and subcutaneously, in phlorhizin diabetes. O. H. GAEBLER AND J. R. MURLIN. *J. Biol. Chem.* **66**, 731-81(1925).—See *C. A.* **19**, 3539.

A. P. LOTHROP

Chemistry and pharmacology of a new benzyl compound (Betilon). U. HINTZELMANN, G. JOACHIMOGLU AND H. OHLE. *Biochem. Z.* **164**, 126-34(1925).—Betilon is the name proposed for $\text{PhCH}(\text{SO}_3\text{Na})\text{CO}_2\text{CH}_2\text{Ph}$. This can be crystd. from 95% alc. on adding ether, in glass-like needles contg. 1 mol. H_2O of crystn. This is lost when the substance is kept over CaCl_2 . The crystals melt at 106° and undergo decompn. at about 200° . Boiled with dil. HCl, Betilon hydrolyzes into mandelic acid, benzyl alc. and H_2SO_4 . It gives insol. salts of brucine or strychnine which crystallize so well that they can be used for the identification of Betilon. In a concn. of 1:400 it produces a marked dilatation of the guinea-pig uterus, which is obvious also with a 1:1500, but not with a 1:2000 concn. It causes also loss of tone of the intestine (rabbit), smooth muscle and blood vessels. A soln. of 0.5 g. in 10 cc H_2O injected into a rabbit causes death in about a minute, probably as a result of the great drop in blood pressure.

S. MORGULIS

Sensitivity of thyroidectomized dogs to insulin. B. A. HOUSSEY AND A. CISNEROS. *Compt. rend. soc. biol.* **93**, 877-8(1925); cf. *C. A.* **19**, 1312.—In thyroidectomized dogs under the influence of insulin the blood sugar does not fall much more slowly and reaches a somewhat lower level than in control dogs.

S. MORGULIS

The action of dimethylguanidine on the vascular system of the frog. T. ENGLUND. *Skand. Arch. Physiol.* **47**, 15-47(1925).—Dimethylguanidine-HCl is a vasoconstricting substance, the activity of which depends upon the presence of a sufficient concn. of Ca. In the absence of Ca from the perfusion fluid there is inversion of the guanidine effect, which becomes one of vasodilatation. The effect of the increasing concn. of Ca in strengthening and prolonging the constrictor action is attributed to the influence of the motor element of the sympathetic innervation. However, K is also necessary for the constrictor action which becomes feeble in the absence of K, while an increase in the K content of the perfusion fluid diminishes the constricting effect of guanidine or even alters it to a dilating effect. The latter effect is attributed to the relative diminution of the Ca concn. Under the influence of atropine guanidine exerts a constricting effect even in the absence of Ca which indicates that the guanidine may act directly on the muscles. Ergotamine diminishes or even inverts the constrictor action of the guanidine which indicates that the sympathetic end organs are likewise concerned in the vasoconstrictor effect.

S. MORGULIS

The cardiac effect of lobeline. BO CLAESON. *Skand. Arch. Physiol.* **47**, 48-77(1925).—With concn. of 0.1 cc. 0.0001% lobeline soln. there is a slight diminution in the systole without any effect on the diastole or pulse rate; but with similar quantities of 0.01-0.1% soln. there is an increased cardiac tone together with a small increase in the pulse rate. When 0.1-0.6 cc. of a lobeline decoction is used there is a diminution of the systole without any alteration in the diastole, and after 0.5-1 min. there is a progressively increasing arrhythmia cordis with considerable reduction of the pulse frequency. Expts. with atropine show that the decoction has no definite effect on the parasympathetic end organs, while its inhibitory action on the heart is not noticeably

influenced by the absences of either K or Ca ions from the perfusion fluid. Furthermore, lobeline has no ability to alter the effect produced by acetylcholine, which indicates that it cannot act upon the irritability of the parasympathetic end organs, nor can it alter the response of the sympathetic end organs to adrenaline. Lobeline, even in massive doses, has no influence upon the results of vagus stimulation. But acetylcholine may to a certain extent invert the cardiac effect of the lobeline. This alteration in the lobeline action by acetylcholine can, therefore, not be due to a paralyzing influence of the lobeline on the vagus end organs but to its ability to displace from the parasympathetic end organs substances which stimulate them. S. MORGULIS

Effect of saponins on muscle. C. G. SANTESSON. *Skand. Arch. Physiol.* 47, 78-101(1925).—Saponin added to Ringer soln. in which frog muscles are suspended causes a quick onset of spontaneous contracture which increases still further on being stimulated electrically, the contracture being 2-3 times as great as can be produced by such stimuli ordinarily. The muscle is a very sensitive reagent for testing the strength of a saponin soln. Neither cocaine nor novocaine can stop the contracture, though they can reduce considerably its degree. S. MORGULIS

Bismuth in the therapy of syphilis with case reports. O. L. MULO. *Ann. Clin. Med.* 4, 307-13(1925).—Large doses are of value where other drugs fail. J. T. MYERS

Report of the treatment of erysipelas with mercurochrome-220 soluble. W. B. ELDREDGE. *Ann. Clin. Med.* 4, 333-5(1925). JOHN T. MYERS

The effect of magnesium sulfate on the cerebrospinal fluid pressure and on the brain volume. E. J. MORRISSEY. *Arch. Surg.* 2, 778-89(1925).—In man 45 g. of $MgSO_4$ by mouth does not cause a drop in spinal fluid pressure in 2 hours. A slight fall of intracranial pressure was noted in a few animals. Apparently brain vol. is not changed in 40 min. following the injection of a large amt. of $MgSO_4$ into the small intestine. JOHN T. MYERS

Observations on the action of the convulsant thujone. H. FLOREY. *J. Path. Bact.* 28, 645-50(1925).—A preliminary fall in blood pressure occurs because of direct action on the heart muscle. A subsequent rise is due to action on the vasomotor center. JOHN T. MYERS

Action of the base tropine on the heart. RENÉ HAZARD and L.-J. MERCIER. *Compt. rend.* 181, 526-8(1925).—Expts. with dogs proved that tropine retards the rate and diminishes the systolic amplitude of the auricles and ventricles. This action differs from that of atropine which at first causes acceleration. With the frog, however, atropine causes a slowing of the heart similar to that caused by tropine. Large variations are shown in the susceptibility to tropine by different individuals, thus, an injection of 0.05 g. per kg. caused death in one dog, while another dog showed only a retardation of rate and diminution of systolic amplitude after a dose of 0.3 g. per kg. L. W. RIGGS

Toxicity of certain alkaloids for the dogfish. Chlorine content before and after injection. R. F. LÉGUION. *Compt. rend.* 181, 820-1(1925).—Injections of neutral strychnine sulfate, neutral atropine sulfate, nicotine, pilocarpine-HCl and morphine-HCl were severally made in the dogfish. The drugs were in 1% or 0.1% soln. in sea water. Acids and bases are more toxic to fish than alkaloids, and the latter are less toxic to fish than to man. The Cl content of the blood was increased after injection of atropine, morphine or pilocarpine, but was notably decreased after injections of strychnine and slightly decreased after the injection of nicotine. L. W. RIGGS

Alkaloidal derivatives with attenuated toxicity. MAX POLONOVSKI and MICHEL POLONOVSKI. *Compt. rend.* 181, 887-8(1925); cf. *C. A.* 19, 289, 1426, 1700, 2500, 2957. Geneserine is similar to eserine in its physiol. and therapeutic actions but is less toxic. Perhaps geneserine may be substituted for the bases from which it is derived. In tests with dogs the lethal doses of geneserine and certain derivs. in g. per kg. were as follows: geneserine 0.02, genatropine 0.2, genhyoscyamine 0.15, genoscolamine 0.2, and genostrychnine 0.02. The latter acts like strychnine rather than geneserine. L. W. RIGGS

Some unrecognized dangers in the use of and the handling of radioactive substances, with especial reference to the storage of insoluble products of radium and mesothorium in the reticulo-endothelial system. H. S. MARTLAND, PHILIP CONLON and J. P. KNEF. *J. Am. Med. Assoc.* 85, 1769-76(1925).—The cases described represent a hitherto unrecognized form of occupational poisoning. The anemias encountered are proved to be due to the ingestion of radioactive elements with the deposition of insol. fixed particles in the phagocytic cells of the sinusoids of the reticulo-endothelial system, where they continuously emit irritative rays, which in time produce exhaustion of the adjacent hematopoietic centers. L. W. RIGGS

The use of ether in pertussis by intramuscular and rectal injection. ALTON GOLDBLOOM. *J. Am. Med. Assoc.* **85**, 1791-3(1925).—Histories are given of 18 cases treated by intramuscular injection of ether, and of 21 cases by ether in olive oil by rectum. The latter method of administration appears to have advantages. While ether may not be regarded as a cure for whooping cough, it often may bring a relief, especially to infants, which proves to be life-saving.

Sodium thiosulfate in treatment of metallic intoxication. H. A. KUHN AND H. H. REESE. *J. Am. Med. Assoc.* **85**, 1804-8(1925).— $\text{Na}_2\text{S}_2\text{O}_3$ has been found efficacious in the treatment of arsenamine dermatitis and jaundice, and in acute As and Hg poisoning. The treatment increases the excretion of As and hastens the restoration of the kidneys to normal. Saline soln. is recommended as the solvent when $\text{Na}_2\text{S}_2\text{O}_3$ is given by mouth. **Sodium thiosulfate in mercurial poisoning.** C. C. HASKELL, W. C. HENDERSON AND J. R. HAMILTON. *Ibid* 1808-10.—Expts. with dogs poisoned by HgCl_2 (4 mg. Hg per kg.) proved that $\text{Na}_2\text{S}_2\text{O}_3$ is of no value as an antidote for Hg that has entered the circulation.

Renal function. Results of experimental work with morphine and atropine. W. H. HAINES AND L. F. MILLIKEN. *J. Am. Med. Assoc.* **85**, 1853-5(1925).—Morphine and atropine, in the usual hypodermic dose, do not affect kidney function unfavorably. Ether anesthesia inhibits kidney function in dogs, and morphine and atropine given prior to the anesthetic prevent this inhibition. Clinical observation and expts. indicate that morphine and atropine have the same effect on kidney function in man during ether anesthesia that they have in exptl. animals. The use of morphine and atropine in urologic surgery is recommended.

Carbon dioxide as an aid in general anesthesia. J. S. LUNDY. *J. Am. Med. Assoc.* **85**, 1953-5(1925).— CO_2 in moderate concn. assists in producing anesthesia, rendering the anesthetic apparently safer and easier to administer. It should be used in such concn. as will produce optimal results, and these vary with the individual and the type and stage of the operation. Too much CO_2 is worse than none. Care should be exercised to prevent more than 5% being used. These conclusions follow from observations in 1350 cases at the Mayo Clinic.

Present status of hexylresorcinol as an internal urinary disinfectant. VEADEE LEONARD AND AUSTIN WOOD. *J. Am. Med. Assoc.* **85**, 1855-9(1925); cf. *C. A.* **20**, 451.

Dangers in the use of certain halogenated phthaleins as functional tests. W. H. ROSENAU. *J. Am. Med. Assoc.* **85**, 2017-20(1925).—Following the use of phenol-tetrachlorophthalein, thromboses, local inflammatory reactions at the site of injection, and chills have been observed. Clinical and exptl. work indicates the possibility of strain or damage to the liver, following injection of the dye. Attempts to make the dye nonirritating on injection have failed. Severe toxic reactions have been observed following the use of tetrabromophenolphthalein, and tetraiodophenolphthalein.

Narcotics and the blood serum. E. HISINGER-JÄGERSKIÖLD. *Finska Läkaresällskapets Handlingar* **57**, 880(1925); *J. Am. Med. Assoc.* **86**, 160.—No change in the P content of the blood serum was observed in 15 medical students after test injection of 8 different narcotics. The Ca content rose in some, dropped in others, and was unmodified in another group. It appears that during a tranquil mental state the Ca content declines.

The intravenous administration of resorcinol. I. The direction and mechanism of its action. J. LUKÁCS. *Magyar Orvosi Archivum* **26**, 527-34(1925).—The actions following the intravenous injection of resorcinol are temp. rise, leucocytosis and consecutive leucopenia, changes of the colloidal blood picture by increased labile fractions, transient elevation of blood sugar, increase of agglutinin titers and increased diuresis. The action appears to be composed of 2 phases: unsp. irritation attributed to changes of the serum albumins, and parasympathetic irritation corresponding to phenol action.

The toxic effects of lead administered intravenously. W. B. BELL, W. R. WILLIAMS AND L. CUNNINGHAM. *Lancet* **1925**, II, 793-800.—Blood changes and pathol. lesions in the tissues are cited.

Experimental pathology of the vascular system in lead intoxication. I. Effect of lead salts on the vessels of isolated organs. ALEXANDER TSCHERKESS. *Arch. exptl. Path. Pharm.* **108**, 220-9(1925).—In a concn. of from 1:1000 to 1:10 million the salts of Pb (acetate and nitrate) cause a constriction of the vessels of the isolated organs (ear, kidney, spleen) of the rabbit. The vascular system of the abdominal organs is more susceptible to Pb and reacts more intensely than do the peripheral

vessels. The mode of action of Pb depends upon its effects upon the smooth musculature of the vascular walls. G. H. S.

Experimental pathology of the vascular system in lead intoxication. II. Functional changes in the vessels. ALEXANDER TSCHERKESS AND E. PHILIPPOWÁ. *Arch. exptl. Path. Pharm.* 108, 365-76(1925).—In chronic exptl. Pb intoxication of rabbits functional damage occurs in the vascular system of isolated organs. The vasodilating app. is affected early and intensely. Vasodilating substances, such as caffeine, chloral hydrate, etc., not only fail to dilate the vessels, but indeed diminish the vascular vol. The effect of vasoconstricting substances, as adrenaline and BaCl_2 , is not modified. Qualitatively the character of the effect on the internal organs (kidney and spleen) is the same as that on external tissues (ear), but quant. the functional damage is greater to the internal organ. In subacute Pb intoxication both the constricting and dilating functions of the vessels are paralyzed. G. H. S.

Acute and chronic poisoning by heavy metals. I. Manganese. H. HANDOVSKY, H. SCHULZ AND M. STAEMMLER. *Arch. exptl. Path. Pharm.* 110, 265-80(1926).—Smaller amts. of Mn are required to kill an animal during a chronic than during acute intoxication, the citrate being definitely more toxic than other compds., doubtless because of its more rapid adsorption. Mn is excreted very quickly in the feces (amts. up to 50% of that injected) while even after protracted periods of administration only traces appear in the urine, indicating the impermeability of the kidney for Mn. Very large amts. of Mn are to be found in the bile, in ascitic fluid, and in pus, showing that the body eliminates the metal by these pathways far more readily than by way of the kidney. Changes in capillary permeability due to pathol. processes render the vessels more permeable for heavy metals. Very large amts. of Mn are to be found in the bone, since here large amts. of carbonate and phosphate are available for pptn. Study of bone is of more importance in metal poisoning than has been assumed. The amt. of Mn in the different organs in fatal poisoning is not necessarily related to anatomical changes in the organs. A large amt. of Mn is invariably deposited in some organs, such as the spleen and brain; in others, as the liver, the amt. present varies over very wide limits, while in some organs, such as the lung, very little is deposited. Why there is sometimes much, sometimes little in the liver, cannot be detd., but it must be due to some cause purely local in the organ, and is secondary to the intoxication phenomenon as a whole. The histopathol. findings include fatty changes in the Kupffer cells, in other cells of the liver and at times in the kidney and heart; and a destruction of red blood cells, as indicated by the formation of hemosiderin. The mechanism of the intoxication with Mn differs in the acute and chronic forms, as is true with other heavy metals. In acute intoxication there is a progressive paralysis of the central nervous system and arrest of the heart. Acute intoxication occurs when a fixed but very high concn. of Mn in the blood is attained. If this concn. is not reached the nervous symptoms do not appear, but the liver becomes involved in irreversible changes, as in chronic intoxication, where the liver, and especially the Kupffer cells, are first attacked. It is suggested that the recognized effect of Mn on antibody production may be allied to this action on the liver. G. H. S.

Vasodilating action of adrenaline and stimulation of the sympathetics. W. FELDBERG, HAHN AND SCHILF. *Arch. ges. Physiol.* (Pflüger's) 210, 697-707(1925).—After a preliminary treatment of the frog-vessel prepn. with suitable amts. of adrenaline a further addn. of adrenaline, or stimulation of the sympathetics, causes vasodilatation. Under both circumstances the initial concn. of adrenaline necessary to lead to this reversal of action is the same. G. H. S.

Morphine miosis. V. E. HENDERSON AND R. W. GRAHAM. *J. Pharmacol.* 26, 469-78(1926).—Morphine miosis in dogs is due to a stimulation of subcortical structures, probably in the corpora quadrigemina. It does not appear to be due to changes in CO_2 combining power or p_{H} of the blood. In rabbits the miosis produced by morphine appears to be due to the increased CO_2 combining power of the blood and possibly to the decreased p_{H} . C. J. WEST

I—ZOOLOGY

R. A. GORTNER

The influence of theophylline on tadpoles. A. FRÖHLICH AND E. ZAK. *Klin. Wochschr.* 4, 2303-5(1925).—Theophylline enhances the growth and, therefore, the weight of tadpoles. MILTON HANKE

Hydrogen-ion concentration and oxidation-reduction potential of the cell-interior before and after fertilization and cleavage: a micro-injection study on marine eggs.

JOSEPH NEEDHAM AND DOROTHY M. NEEDHAM. *Proc. Roy. Soc. (London)* 99B, 173-99 (1926); cf. *C. A.* 19, 3493.—Study was made of 3300 injected eggs, including those of 4 species of echinoderms, 1 species of tunicate, and 1 species of polychaete worm. The internal p_H of all the eggs studied was close to 6.6; it was not altered by fertilization, remained const. as far as the 16-cell stage, did not show rhythmical change, and was not influenced by local injury or by morphological degeneration of asphyxia until cytolytic changes had begun. Cytolysis changed the p_H to a value between 5.0 and 4.0. The τ_H of the cells varied more than the p_H , but remained between 19 and 22; it did not change on fertilization, remained const. as far as the 8-cell stage, and apparently was not influenced by cytolysis. Micro-injection is superior to vital staining since (1) substances to which the normal cell-wall is impermeable can be introduced into the cell with little or no injury to the latter; and (2) the method is so rapid and the amt. of dye so minute that far less danger exists of an upset in the original equil. of the cell, and the establishment of an unnatural equil. In vital staining, the cell probably is far removed from its physiol. normal by the time staining is complete. J. S. H.

The permeability of the intestine of holothurians. H. A. P. C. OOMEN. *Verslag Akad. Wetenschappen Amsterdam* 34, 1028-35(1925).—No active absorption of isotonic solns. by the live or surviving wall was found. The phenomena reported by other authors may be caused by the activity of amebocytes. MARY JACOBSEN

Physiologic reactions of *Spirostonum ambiguum* Ehrenberg to stimulation. H. BLÄTTNER. *Arch. Protistenk.* 53, 253-311(1926).—This organism reacts like paramecium to various chemical stimuli: AcOH, H₂SO₄, HCl, HNO₃, H₂CO₃ and chromic and picric acids; KOH and NaOH; NaCl and Na₂CO₃; alcohol and sucrose. *Spirostonum* can bear the cold well but is more active in warm environment. Its rheotaxis is positive. Increase in CO₂ enhances geotaxis. Normally, there is no reaction to light. However, through the aid of certain dyes (fluorescent as well as non-fluorescent) a negative phototaxis may be induced. The resistance to harmful effects of light is then greatly lowered. FRANCES KRASNOW

Modification of development on the basis of differential susceptibility to radiation. II. *Arbacia* and visible light following sensitization. MARIE A. HINRICHS. *Biol. Bull. Marine Biol. Lab.* 50, 1-10(1926).—Expts. with fertilized *Arbacia* eggs proved that the effectiveness of photodynamic sensitization depends upon exposure of the sensitized system to radiation of sufficient intensity and duration, which in order to be absorbed and so become effective, must have a wave-length range including that of the absorption band of the particular sensitizer used. The susceptibility to visible radiation following sensitization with the following sensitizing dyes (eosin, benzoflavine, neutral red and methylene blue) is differential, *i. e.*, regions of high physiol. activity are first to be modified in their development. Differential inhibition, recovery and acclimation have been produced in this way. It is possible to produce these effects (as with *Fundulus* and ultra-violet radiation) by exposure during the first few min. after fertilization, indicating an early difference in susceptibility of various regions of the egg. Differential modification is also obtained by fertilizing normal eggs with photodynamically treated sperm. These expts. confirm the view of the nonsp. and quant. nature of susceptibility relations along the body axis. L. W. RIGGS

The cause and nature of encystment in *Polytomella citri*. J. MCA. KATER AND R. D. BURROUGHS. *Biol. Bull. Marine Biol. Lab.* 50, 38-54(1926).—The culture medium was prepd. by boiling about 10 g. of timothy hay in 1 l. of distd. water. Attempts were made to det. the effect of various temps., H-ion concns., metabolic products and food deficiency on the tendency to encyst. *Polytomella citri* encysts only when the cell body contains considerable starch. Encystment is not due to any perceptibly adverse environmental factors. Optimum conditions for growth and reproduction are concomitant with max. encystment. Prevention of encystment, either by continuous transfer or by low temp., if carried to sufficient extent, will result in morphological degeneracy and loss of the tendency to store starch and to encyst. L. W. R.

Production of light by a nudibranch mollusk of New Caledonia. RISBEC. *Compt. rend.* 181, 472-3(1925).—This nudibranch appears to be the first non-pelagic gastropod in which luminous organs have been found. During the night, at the least disturbance, the animal emits 3 to 5 series of 4 to 5 very brief flashes of white light. After this emission new flashes cannot be obtained within one hr., the new emission being less intense. L. W. RIGGS

The role of the lymphocytes and granulocytes in the reparation of injured tissues in the crawfish. L.-M. BÉTANCÈS AND J. DELUNA. *Compt. rend.* 181, 626-8(1925).—A histologic study. L. W. RIGGS

Does the Bunsen-Roscoe law apply in the luminous excitation of invertebrates?

(Result of studies with *Mya arenaria*.) HENRI PIÉRON. *Compt. rend.* **181**, 688-90 (1925).—Expts. show that the law is not valid. L. W. RIGGS

Hemolytic properties of the pedicellariae of certain sea urchins. ROBERT LÉVY. *Compt. rend.* **181**, 690-2(1925).—Pedicellariae of the 3 species of sea urchin studied contain hemolytic toxins which act only in the presence of lecithin, or the vitellus of the fowl. Tridactyls, which have no glandular pockets as do the pedicellariae, also carry these toxins. The hemolysis by these toxins is by a catalytic process analogous to that of poisonous venoms. L. W. RIGGS

12—FOODS

W. D. BIGELOW

Iron in food products. C. MASSATSCH. *Pharm. Ztg.* **71**, 58(1926).—A reply to the recent criticism of Troponwerke Dinklage & Co. (cf. C. A. **20**, 951). W. O. E.

Determination of unsaponifiable matter in wheat flour, alimentary pastes and eggs. RAYMOND HERTWIG AND L. H. BAILEY. *J. Assoc. Official Agr. Chemists* **9**, 122-1 (1926).—The direct Et_2O ext. of flour and eggs does not contain all the unsapon. matter of these materials. Hertwig's acid hydrolysis extn. method (C. A. **17**, 2621) apparently has some chem. action on the unsapon. matter which causes low results for flour and eggs. The official A.O.A.C. neutral method for lipid extn. of flour, alimentary pastes and eggs gives the highest results, is believed to be the most satisfactory from the standpoint of operation for general purposes, and seems to be the most accurate.

A. PAPINEAU-COUTURE

Raising dough by means of pure yeast cultures. G. SCHLBER AND (MISS) G. BOVSHIK. *Bull. inst. Lesslafs Leningrad* **1924**, 10; *Bull. assoc. inst. sup. fermentation Gand* **27**, *Ann. soc. brasseurs* **35**, 70(1926).—Working with a rye flour dough, S. and B. found that it rose if the yeast added corresponded to 141,000 cells, or over, per g. of dough, the rate of rise increasing with the amt. of yeast added. The use of pure cultures in liquid medium requires less raw material in the prepn. of the yeast needed for a given amt. of dough than the use of pressed yeast.

A. PAPINEAU-COUTURE

Preparation of benzoic acid. A. B. LORGES. *Rev. chim. ind.* **35**, 10-4(1926). Description of the manuf. of technical BzOH and of pure BzOH for food and pharmaceutical use.

A. PAPINEAU-COUTURE

Detection of dyes in caramel. L. V. NOEL. *Pharm. Zentralhalle* **67**, 33-5(1926). Among other exptl. findings it is shown that the unequivocal detection of dyestuffs in caramel is best effected in relatively high diln. A redyeing of the thread used in the test is essential and tartaric acid as fixing agent is preferable to KHSO_4 . Furthermore, natural dyestuffs behave very like caramel, the former being fixed in concd. soln. on wool in such quantity as to render wool thus treated less susceptible to added dyestuffs, while in dil. soln. such added dyes are more readily fixed on the wool than the natural dye. This property becomes more apparent on redyeing, since only a portion of the natural dye is rendered sol. on treatment with dil. NH_3 , so that in the resulting highly dild. soln. the artificial dyestuff greatly exceeds the natural, which subsequently is scarcely pptd. on the wool, thus making detection of the added dye relatively certain.

W. O. E.

Determination of water in honey with the immersion refractometer. WILHELM MÜLLER. *Mitt. Lebens. Hyg.* **16**, 261-5(1925); cf. Behre, C. A. **16**, 2558.—The refraction of 20% honey soln. is detd. with a Zeiss immersion refractometer and the refractive index obtained from the tables. The water content is then found from sugar tables. This agrees within 0.5% with gravimetric and pycnometric detns., a closer check than is found between duplicate gravimetric detns. F. L. SEYMOUR-JONES

Determination of sucrose. HEINRICH FINCKE. *Z. Nahr. Genussm.* **50**, 351-65 (1925).—An extension of the work of Hasse and Bake (C. A. **17**, 3059). Tables of correction factors are given for polarimetric detn. of sucrose in chocolate, cocoa-sucrose mixts. and milk chocolate.

WILLIAM J. HUSA

The refractometric determination of vanillin in vanillin-sugar. E. ARBENZ. *Mitt. Lebens. Hyg.* **16**, 265-8(1925); cf. Utz, C. A. **18**, 3088.—Vanillin-sugar is a new product, being a mixt. of synthetic vanillin with finely powdered sugar. Dissolve 3 g. in 20 cc. anhydrous acetone, filter and det. the refraction with a Zeiss immersion refractometer at 17.5° . A table giving vanillin content against Zeiss scale degrees is given.

F. L. SEYMOUR-JONES

Imitation vanilla essence. J. C. MACLAURIN. *Analyst* **50**, 548-9(1925).—An

interesting law suit is described in which the official chemist found an essence to contain added vanillin and won the case in spite of an ingenious defense. W. T. H.

Pectin and the patents on its manufacture. M. R. DAUGHTERS. *Canning Age* 1926, 110-2.—The development of pectin is traced through the several patents issued to cover its manuf. T. MARKOVITS

The microscopical examination of ground nutmeg. CATH. H. KOPERBERG. *Chem. Weekblad* 23, 62-4(1926).—Admixture of seed coat (testa) can be detected by the presence of a relatively large proportion of oblong, lignified cells which give the phloroglucinol reaction. A small amt. of these cells may be derived from the perisperm, which is not considered an adulterant. MARY JACOBSEN

Determination of cacao shell in cacao. CATH. H. KOPERBERG. *Chem. Weekblad* 23, 64-6(1926).—The stone cells in 2 g. defatted cacao are counted and compared with standards contg. a known percentage of shell. The results are only approx., since com. samples are not sufficiently uniform. MARY JACOBSEN

Formaldehyde in certain marine products. D. B. DILL AND P. B. CLARK. *J. Assoc. Official Agr. Chemists* 9, 117-22(1926).— CH_2O is shown to develop in sterile canned crustacea and so-called red rock cod (*Sebastes sp.*). This development of CH_2O is independent of the nature of the container and of the processes of can corrosion or of the blackening of these products from formation of Fe sulfide. It takes place in the absence of free O. Acidification and steam distn. failed to recover more than one-third of the CH_2O added to CH_2O -free salmon. Up to 1 part CH_2O in 30,000 parts of canned crustacea was found, which would indicate that they may contain up to 1 part in 10,000. A. PAPINEAU-COUTURE

Grading as to size of green peas for canning. ED. LASSAUSE. *Ann. fals.* 19, 28-40(1926).—Owing to changes in the size of peas during and after blanching, screening of the peas a few months after canning will not correspond to the screening of the raw peas. A large no. of analyses before and after canning showed no marked relationship between size and chem. compn. On calcg. the analytical results per 100 peas (instead of % by wt.) a certain gradation of the chem. compn. according to size was noted; but it held only for the product of a given district and for a given harvest. A. P.-C.

"Avgotarachon." CONSTANTIN PYRIKI. *Z. Nahr. Genussm.* 50, 366-71(1925).—Description, photographs and analyses of "Avgotarachon," a fish-egg delicacy prepared in Greece, Turkey and Egypt. WILLIAM J. HUSA

Sultana drying by the cold dip process. FRANCOIS DE CASTELLA. *J. Dept. Agr. Victoria* 23, 716-31(1925).—The cold dip process promises two marked improvements in sultana drying: (1) Improvement in color, which is bright golden instead of brown. (2) Absence of stickiness in the finished fruit, owing to the skin not being broken, hence elimination of the sugary appearance on storage. Its principal defects are (1) slower drying and more rack space. (2) the presence of odd, dark berries, which are rendered more conspicuous by the lighter color of the general sample. The process consists in the substitution of a cold K_2CO_3 soln. for the hot NaOH dip previously used. The concn. of the soln. is usually about 1 lb. K_2CO_3 to 2 gals. H_2O . To this soln. olive oil is added, about 1 pt. to 50 gals. of soln. During drying the fruit is sprayed two or three times with ordinary dip soln. in which the proportion of oil is slightly increased. When nearly dry the fruit is bleached or finished on strips of hessian lying on the ground, to which it is transferred from the racks or trays. Bleaching develops the desired golden tint. This is aided by an additional spray. Final washing is often beneficial and sometimes necessary to remove any excess of K_2CO_3 left by the spraying. This is effected by dipping in a weak K_2CO_3 soln., 1° Baumé, with olive oil at the rate of 1 pt. to 50 gals. RUSSELL M. JONES

Determination of milk fat in foods. J. KUHLMANN AND J. GROSSFELD. *Z. Nahr. Genussm.* 50, 329-46(1925).—The % of milk fat is practically proportional to the Reichert-Meißl no., except in presence of coconut or palm-kernel oils, for which corrections are presented. An accurate description is given of the procedure of Bertram, Bos and Verhagen for the detn. of coconut oil and milk fat in fat mixts., together with a rapid graphical method of calcg. the results. WILLIAM J. HUSA

A study of milk and cream confectionery. J. KUHLMANN AND J. GROSSFELD. *Z. Nahr. Genussm.* 50, 346-51(1925).—The quant. sepn. of the fat of milk and cream confectionery is carried out by dissolving 100 g. of the substance in 400 cc. hot H_2O , coagulating by addn. of 25 cc. Fehling soln. and 25 cc. 0.25 N NaOH, filtering and extg. the dried coagulate with fat solvents. Com. candies frequently contain fats other than milk fat; for detn. of milk fat see preceding abstract. WILLIAM J. HUSA

Sweetened condensed milk. III. In a total solids residue what is the form of lactose? F. E. RICE AND JACK MISCALL. *J. Dairy Sci.* 9, 62-4(1926).—Aq. lactose

solns. were treated by the A.O.A.C. method for detg. total solids in sweetened condensed milk. Lactose was recovered as anhydride. F. L. SEYMOUR-JONES

Humidity equilibria of milk powders. G. C. SUPPLEE. *J. Dairy Sci.* 9, 50-61 (1926).—Drum and spray process powders were held over H_2SO_4 solns. for periods up to 6 months. Above 50% humidity hydration is rapid. It follows a smooth curve irrespective of the process of manuf. except for a break at 50%, which does not occur in dehydration. Excessive heating or previous satn. alters the absorptive properties. There was decreased absorption and retention of moisture with increasing fat content of the milk powder. F. L. SEYMOUR-JONES

Action of rennet extract on the paracasein of skim milk, as affected by different organic acids. C. T. TOWNSEND. *Sci. Agr.* 6, 158-64 (1925).—Skim milk was sterilized with $CHCl_3$ for 24 hrs. Equal vols. of 0.1 and 0.2 N lactic, acetic and propionic acids were added together with rennet and all held one week at room temp. With 0.1 N acids lactic and propionic were equal and gave greater paracasein digestion than acetic or rennet alone. With 0.2 N acids acetic and propionic were equal and more digestive than lactic or controls. "With an increase in concn. of acid in the milk at the time of curdling, a corresponding increase in the amt. of paracasein digested by rennin is obtained." F. L. SEYMOUR-JONES

Physicochemical factors influencing cream rising. I. Viscosity. L. S. PALMER AND E. O. ANDERSON. *J. Dairy Sci.* 9, 1-14 (1926).—Cream vols. from raw and pasteurized milk standardized to 3.5% fat content were measured after 24 hrs. at 0° and 10°. Jersey, Guernsey, Holstein and Ayrshire milks were used. Viscosity was detd. with the MacMichael viscometer and p_H potentiometrically. No relation between p_H and viscosity was found. In raw milk cream vol. was largely detd. by the solids not fat content; viscosity varied with solids not fat and with temp. and was a good index of creaming ability. Fat globule size is of minor importance. For pasteurized milk viscosity is not important; creaming is less exhaustive and fat globules are more closely packed. F. L. SEYMOUR-JONES

Factors influencing the viscosity of cream and ice cream. F. F. SHERWOOD AND H. L. SMALLFIELD. *J. Dairy Sci.* 9, 68-77 (1926).—Cream in aging sometimes increased in viscosity. Where this occurred there was a greater grouping together of fat globules with consequent fixation of part of the free serum. F. L. S.-J.

Detection of annatto in milk. A. D. GARDINER. *Analyst* 50, 549-50 (1925).—The following modification of Leach's method has been found very satisfactory. Coagulate 25 cc. of milk in a 100 cc. conical flask by heating to 50° and adding 0.2 cc. of AcOH. Filter off and press the curd. Return it to the original flask and shake with 75 cc. of ether. Allow to stand overnight. Pour off the ether, ext. into a porcelain evap. dish and evap. to dryness. As soon as the dry stage is reached, add 6 cc. of 0.1 N NaOH, stir and transfer to a wet filter paper. When all the liquid has drained through the filter, and only fat remains, open the paper, spread it on a watch glass, wash it with hot water and dry. An orange tint is imparted to the paper and the presence of annatto can be confirmed by the pink color produced upon adding a drop of $SnCl_4$ in citric acid. W. T. H.

Some factors affecting the growth of certain strains of *P. roqueforti*. I. Blue mold. N. S. GOLDING. *J. Dairy Sci.* 9, 28-36 (1926).—Citric and acetic acids in amts. comparable with those found in starters in Wensleydale cheese have a distinct effect on the growth of different strains of *P. roqueforti*. Low concns. of acetic acid tend to reduce the digestion of casein in milk by the blue mold, while citric acid has the opposite effect. However, in a special medium contg. lactose, peptone, agar and 4 salts, the contrary was true, namely, acetic acid increased the growth of the organism while citric acid tended to inhibit the growth. These facts have a direct bearing on the results to be obtained with different kinds of starter, for a preponderance of acetic or citric acid will directly affect the growth and activity of *P. roqueforti*. G. F. REDDISH

Saltbushes and their allies in the United States. G. L. BIDWELL AND E. O. WOOTEN. U. S. Dept. Agr., *Bull.* 1345, 1-39 (1925).—Proximate analyses are given of 64 varieties of native plants of the arid and semiarid United States with comments on their forage value for range animals. A bibliography of 30 literature references is appended. W. H. ROSS

Detection of As in cacao (LÜHRIG) 7. The purposes and aims of agricultural chemical analysis (BROWNE) 7.

DOWD, MARY T. AND JAMESON, JEAN D.: **Food, its Composition and Preparation.** 2nd ed., revised. New York: J. Wiley & Sons, Inc. 177 pp. \$1.50.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Biography of Dr. John C. Thresh. ANON. *Water and Water Eng.* 27, 430(1925). JACK J. HINMAN, JR.

Recent studies relating to the purification of water. J. C. THRESH AND J. F. BEALE. *Surveyor* 68, 579(1925).—With river waters which sometimes vary rapidly the "excess lime" method of water treatment must be carefully controlled. Water exposed to the air in certain places has been shown to absorb sufficient impurities of a phenol-like nature to give a disagreeable taste in subsequent chlorination. *B. coli* has been shown to multiply in water in the presence of "*Enteromorpha intestinalis*" and "*Oscillatoria nigra*." Silicate of soda prevents the oxidation of Pb by O-bearing water. Also in *Water & Water Eng.* 27, 475-8(1925). R. E. GREENFIELD

Stream pollution in Ohio. W. H. DITTOE. Ohio Conference on Water Purification, Fourth Ann. Rept. 1925, 10-3.—Progress in the survey of stream pollution which is being conducted by the State Dept. of Health is reviewed. In discussion it was stated that excess Cl treatment for eliminating taste due to phenol was found ineffective in lab. expts. at Cleveland. R. E. THOMPSON

The Cincinnati water-works system. CLARENCE BAHLMAN. Ohio Conference on Water Purification, *Fourth Ann. Rept. 1925*, 68-74.—The water-purification plant is described and data on operation are given. Coagulation is effected with lump CaO and iron sulfate. The cost of operation during 1923 was equiv. to \$6.76 per million gal. delivered into service, of which \$2.44 was expended on chemicals. R. E. THOMPSON

Water purification at East Liverpool, Ohio. D. H. RUPP. Ohio Conference on Water Purification, *Fourth Ann. Rept. 1925*, 47-59.—Tabulations of bacteriol. data for 1923 are given. Coagulation removes 81-87% of raw water bacteria, filtration 77-84% of bacteria applied, and chlorination 94-97% of bacteria surviving filtration. The raw Ohio River water contains an av. of 4 p.p.m. of sol. Fe and there is probably several times that amt. of sol. Al. This explains the comparatively small amt. of coagulant required, 0.7 to 1.5 grains per gal. Since water purification has been adopted, the typhoid death rate has decreased from 75.8 to 4.4 per 100,000. Considerable difficulty has been experienced with tastes due to pollution of supply with phenol wastes, the taste complained of being that of phenol rather than chlorophenol. A phenol content of 0.1 p.p.m. invariably results in complaints. Results of lab. studies on the effect of various methods of treatment on the phenol content of water are summarized. R. E. THOMPSON

The new water purification plant at Toronto, Ohio, employing double coagulation of Ohio River water. D. H. RUPP. Ohio Conference on Water Purification, *Fourth Ann. Rept. 1925*, 65-7.—The new coagulation and filtration plant at Toronto is described. Double coagulation is employed at all times, it having been found that best results with least application of chemicals can be obtained thereby. The amt. of alum used has averaged 3 grains per gal., in approx. ratio of 2.1 to the first and second basin, resp., and lime employed has averaged 2 grains per gal. R. E. THOMPSON

Pollution and natural purification of the Ohio River. III. Factors concerned in the phenomena of oxidation and re-aeration. H. W. STREETER AND E. B. PHELPS. U. S. Pub. Health Service, *Bull.* 146, 75 pp. (1925); cf. C. A. 19, 3333.—Observations were made during the year 1914-15 at sampling stations along the Ohio of the dissolved O in the river water and the biochem. O demand of the river water. It was found that only $\frac{1}{4}$ of the purification was due to diln. and that $\frac{3}{4}$ was due to re-aeration. The theory of the O demand upon a stream and the O resources of a stream is treated in a mathematical manner, and the results obtained are applied to the same factors in the case of the Ohio. The self-purification of the river as far as concerned its O content was found to be a measurable phenomenon capable of expression by a mathematical formula. On account of this definite expression the same principle can be applied to the examn. of all polluted streams. B. C. A.

Further observations on the biology of Jersey Water Works. W. RUSHTON AND P. A. AUBIN. *Surveyor* 68, 557; *Water & Water Eng.* 27, 487-9 (1925).—The use of CuSO_4 spray as a means of controlling algae is the most effective method. The presence of large nos. of "Asterionella" did not in 1 case produce an odor. A weekly count of microscopic organisms gives a sufficient indication of the condition of growth in the reservoirs studied. R. E. GREENFIELD

Use of pebble quick lime. ANON. Ohio Conference on Water Purification, *Fourth Ann. Rept. 1925*, 41-2.—Substitution of pebble CaO for $\text{Ca}(\text{OH})_2$ at the Columbus and Delaware plants gave satisfactory results and effected considerable economy in operating costs. R. E. THOMPSON

Dry feed of coagulants. P. J. O'CONNOR, W. I. VAN ARNUM AND E. C. LINDSEY. Ohio Conference on Water Purification, *Fourth Ann. Rept. 1925*, 36-41.—Experiences with dry feed of chemicals at Warren, Youngstown and Ravenna indicate that the Gauntt type of machine is not as accurate as Pittsburgh and other types when flow of water varies appreciably. R. E. THOMPSON

Offensive tastes in public water supplies caused by industrial wastes. W. H. DINTON. Ohio Conference on Water Purification, *Fourth Ann. Rept. 1925*, 7-10.—Prevalence of taste and odor due to phenol-contg. wastes and progress in the prevention of the same is reviewed and discussed. Evapn. of liquid wastes from coke plants by employing it for coke quenching appears to be the most satisfactory method of disposal. R. E. THOMPSON

Advantages of lime in water softening. C. P. HOOVER. Nat. Lime Assoc., *Tech. Papers and Addresses 1925*, 70-5.—Lime softening decreases the mineral content of the water. Lime removes CO_2 , which dissolves iron, causing "red water." Lime and alum remove bacteria, color and turbidity by coagulation. K. C. BEESON

Use of sodium aluminate as coagulant. J. P. BROWNSTEAD, E. T. EDWARDS, E. E. SMITH AND C. P. HOOVER. Ohio Conference on Water Purification, *Fourth*

Ann. Rept. 1925, 31-6.—Substitution of Na aluminate for alum ordinarily applied with lime for coagulation during 4- and 2-month exptl. periods, resp., at Ashland, Ky. and Ironton, O., gave good results. Higher bacterial efficiencies with lower cost for coagulant per million gal. treated were obtained with Na aluminate at the former plant. Bottle expts. at Lima, O., indicated that it would not be economical to replace any part of the necessary application of alum with Na aluminate. Lab. studies at Columbus, O. showed that Na aluminate has the same beneficial effect on softening by the lime-soda process as alum. Commercial Na aluminate is also an aid to softening because of its Na_2CO_3 and NaOH content, whereas alum increases the non-carbonate hardness and necessitates the employment of additional Na_2CO_3 . It is estd. that commercial Na aluminate costs from 74 to 135% more than an equiv. mixt. of alum, Na_2CO_3 and lime solns. R. J. THOMPSON

Further investigation into the sterilization of water by chlorine and some of its compounds. C. H. H. HAROLD. *J. Roy. Army Med. Corps* **45**, 190-207, 251-73, 350-63, 429-42; *J. State Med.* **33**, 428-39, 451-77 (1925).—Details of tests showing advantages over Cl of simple chloramines prepd. from Cl and $(\text{NH}_4)_2\text{CO}_3$. A. T. C.

Chloramine treatment of water in the field. C. H. H. HAROLD. *J. Roy. Army Med. Corps* **46**, 115-9 (1926).—In field tests mono- and dichloramine gave satisfactory water with better taste than did Cl. A. T. CAMERON

The Coolgardie pipe line in Australia and measures taken to correct corrosion. F. P. LANGLEY. *J. New England Water Works Assoc.* **39**, 421-44 (1925).—Within five yrs. tuberculation had greatly reduced the carrying capacity of the line and it had perforated in many places. Treatment with lime, while probably preventing further corrosion, deposited an excessive coating which further reduced the carrying capacity of the line. Deaeration by spraying through a partial vacuum results in about a 90% removal of O and while not improving the existing carrying capacity of the line from tests pieces hung in the flowing water it has reduced corrosion especially in those sections of the line farthest removed from deaerator. R. E. GREENFIELD

St. Paul's water consumption and costs in 1924. J. W. KELSEY. *Eng. News Rec.* **95**, 1041 (1925); cf. *C. A.* **20**, 789.—The daily per capita consumption during 1924 was 76.9 gal. As ground water is easily obtained the city supplies only approx. 60% of the total water consumed. The cost of maintenance during the year was equiv. to \$57.37 per million gallons, and total cost, including interest and sinking fund, \$103.35. Services are 100% metered. R. E. THOMPSON

Tampa's new water works. *Public Works* **57**, 1-6 (1926).—The supply, taken from Hillsboro river, has a color variation from 26 to 200 p.p.m. with a hardness of from 30 to 200 p.p.m. The period of max. hardness coincides with the period of min. color. Low lift pumps take the water from the intake wells to the first mixing chamber where it flows by gravity through the entire plant to the filtered water reservoir. It is then pumped through 3 miles of 30 inch force main to the distribution system and to three elevated tanks each of $1\frac{1}{2}$ million gallons capacity. The pumping and purification plants are designed to handle 12 million gallons per day with provisions for a 25% overload. Lime will be added in the first mixing chamber for softening. SO will be added with the alum for decolorizing. C. C. RUCHHOFF

New water works plant for the city of Tallin (Reval) Esthonia. ANON. *Water and Water Eng.* **27**, 437-8 (1925).—A rapid sand filter installation of 5.5 Imp. gallon capacity uses air agitation of the sand bed, and is designed to operate at the rate of 1.5 Imp. gals./sq.ft./min. When heated to 120° F. the water shall have no taste of mud, earth, fishy material, nor of Cl. The org. matter of the filtered water expressed as albuminoid NH_3 shall not exceed 0.5 p.p.m. The filtered water must be neutral to litmus at 175° F. and must not contain more than 20 bacteria per cc. when the applied water contains 3000 per cc. *B. coli* must be absent from 100 cc. J. J. H. JR.

The water supply of Vienna and the possibility of its extension. FRANZ SCHÖN BRUNNER. *Gas u. Wasserfach* **69**, 85-9 (1926).—Discussion of the hydrology of the vicinity. W. B. PLUMMER

The iodoform taste of chlorinated water. B. ADAMS. *Medical Officer, Water and Water Eng.* **27**, 435-6 (1925).—A decided taste which could not be distinguished from that of chlorophenols was given by 1 part per 1000 million of iodoform. Mere trace of alc. or acetone with I in alk. water will give the iodoform reaction. By adding 0.2 p.p.m. I to water contg. 1 p.p.m. alc. or acetone vile tastes of iodoform were produced. Natural waters may have the necessary org. compds. set free from org. matter by bacterial action, and the I might be set free from its compds. by Cl. Chlorophenol tastes are developed instantly, but some time is necessary for the iodoform-like tastes to appear. Superchlorination and KMnO_4 will avoid iodoform tastes, but SO₂ does

not remove the taste. An iodoform taste can be produced in a water contg. 0.005 p.p.m. I. JACK J. HINMAN, JR.

A score system of grading water supplies according to sanitary conditions. E. S. CASE. *J. New England Water Works Assoc.* 39, 229-34 (1925). R. E. G.

Iodine and water supplies. H. W. CLARK. *J. New England Water Works Assoc.* 39, 204-7 (1925).—See C. A. 20, 250. R. E. GREENFIELD

Tastes in the water supply of Marquette, Michigan due to phenol waste. PAUL HANSEN. *J. New England Water Works Assoc.* 39, 320-44 (1925).—See C. A. 20, 249. R. E. GREENFIELD

Chemical and chemico-physical researches on three mineral waters of Agnano (Naples). F. ZAMBONINI, G. CAROBBI AND V. CAGLIOTI. *Ann. chim. applicata* 15, 134-74 (1925).—The source of the waters, designated De Pisis (hyperthermal), Sprudel (hyperthermal) and Marte (subthermal), is in the volcanic region of Agnano. The first two resemble the famous hyperthermal springs of Wiesbaden, Adler and Kochbrunn, the Marte water that of Apollo water. The 3 waters had, resp.: d_4^{25} 1.0055, 1.0075, 1.0014; radioactivity (Maché units per l.) 0.283, 0.132, 0.645, and temp. 75.5°, 70.5°, 27°. Extensive analyses indicate that the compn. is approx. as follows (mg. per l.) for the 3 waters: Li^+ 1.7, 1.5, 0.3; Na^+ 1793.5, 2352.6, 382.2; K^+ 344.7; 650.6, 124.1; NH_4^+ 12.1, 22.6, 6.9; Mg^{++} 41.3, 66.3, 24.3; Ca^{++} 159.4, 220.1, 99.7; Ba^{++} 1.3, 0.6, 0.2; Pb^{++} 0.05, 0.09, —; Mn^{++} 1.2, 3.2, 1.8; Fe^{++} 3.2, 3.0, 8.4; Cl^- 2627.3, 4036.9, 262.9; Br^- 3.6, 5.1, 0.6; I^- 0.2, 0.2, 0.05; SO_4^{--} 245.9, 244.5, 150.8; HPO_4^{--} 0.4, 1.4, 1.0; HAsO_4^{--} 0.17, 0.01, 0.006; HCO_3^- 1214.6, 1100, 1035.2; NaCl 652.1, 1311.2, 17.3; Na_2SO_4 159.9, 206.3, 36; NaHCO_3 389.4, 432.5, 109; KCl 0.4, 93, 2.2; K_2SO_4 9.5, 13.1, 15; KHCO_3 22.6, 28.7, 13.1; NH_4Cl 12.2, 4.8, 0.2; $(\text{NH}_4)_2\text{SO}_4$ 0.5, 0.8, 0.4; NH_4HCO_3 1.4, 1.6, 1.2; MgCl_2 71.2, 161.9, 5.6; MgSO_4 18.2, 26.5, 12.1; $\text{Mg}(\text{HCO}_3)_2$ 45.4, 57.1, 37.6; CaCl_2 168.2, 332.1, 16.7; CaSO_4 41.6, 52.7, 35; $\text{Ca}(\text{HCO}_3)_2$ 102.1, 111.2, 106.8; MnCl_2 —, 2.2, 0.2; MnSO_4 —, 0.3, 0.4; $\text{Mn}(\text{HCO}_3)_2$ —, 0.7, 1.0; FeCl_2 —, 2.1, 1.0; FeSO_4 —, 0.3, 2.2; $\text{Fe}(\text{HCO}_3)_2$ —, 0.7, 6.6; SiO_2 176.8, 151.8, 87.1; TiO_2 0.0025, 0.0015, 0.002; H_2BO_3 1.1, 1.3, 0.7; free CO_2 493.7, 102.8, 1692.4. Various other phys. and chem. const. are given; details of all the methods of analysis followed. C. C. DAVIS

Some recent deep borings in the London basin. H. J. DEWEY, J. PRINGHAND AND C. P. CHATWIN. *Water and Water Eng.* 27, 398-400 (1925). J. J. H., JR.

Period of storage and microorganisms in reservoirs. R. S. WESTON. *J. New England Water Works Assoc.* 39, 225-9 (1925).—In general ample storage decreases rather than increases trouble from microorganisms. R. E. GREENFIELD

Statutory regulation of stream pollution and the common law. E. B. BESSELIEVRE. *Water and Water Eng.* 27, 431-4 (1925).—Largely a review of American practice. JACK J. HINMAN, JR.

Spore-bearing gas-formers in the Ohio River at Cincinnati. HENRY SOHN. *Ohio Conference on Water Purification* 1925, 85-9.—Of 99 samples of Ohio River water examd. for spore-bearing gas-formers, 21 were found to contain such organisms. Only 6 of the 21 positive mixed cultures survived plating and purifying processes and proved capable of fermenting lactose. All 6 were spore-bearers and 4 of them grew aerobically. The remaining 15 positive cultures were apparently due to symbiotic growth of spore-bearing types. The rate of gas formation by the spore-bearing types encountered was too slow to cause serious interference with gas production by colon group organisms. During the same period 85% of routine presumptive positive tests on Ohio River water were confirmed by the usual tests for *B. coli*. R. E. T.

Prevention of deposit in water mains. W. RANSOM. *Munic. & County Eng.* 69, 324-5; *Surveyor* 68, 481-2 (1925).—Deposits of iron formed chemically and by iron bacteria are discussed. Cement lining or coating the pipes with a mixt. of coal tar or pitch oils and rosin is recommended to prevent chem. incrustation. Efficient filtration with the removal of the org. matter will prevent the development of iron bacteria. C. C. RUCHHOFF

The significance of bacteriophage in surface water. LLOYD ARNOLD. *Am. J. Pub. Health* 15, 950 (1925).—Surface waters contg. a high degree of domestic sewage contain bacteriophagic substances in direct proportion to the amt. of pollution. These phages cause lysis of the pathogenic bacteria, thus reducing the probability of epidemics. They also influence bacteriol. examn. for pathogens in these waters. The use of bacteriophages in filtration and sewage treatment is suggested. K. C. BRESON*

The filtration works of the City of Montreal. F. E. FIELD. *J. New England Water Works Assoc.* 39, 208 (1925). R. E. GREENFIELD

Partial purification of sewage by activated sludge. H. C. WHITEHEAD. *Surveyor* 68, 449-50, 473-4 (1925).—The economy of a process involving sedimentation, a

short period of activated sludge, with separate sludge aeration followed by bacteria bed treatment is pointed out. R. E. GREENFIELD

Epsom's new sewage work. ANON. *Surveyor* 68, 347(1925).—The one-half million gallon per day "Simplex" surface aeration plant is put in operation. The plant reduces the O consumed 92.3%, free and albuminoid NH_3 83.3%. R. E. GREENFIELD

Chlorine in sewage and waste disposal. J. C. BAKER. *Can. Eng.* 50, 127-8 (1926).—The development of chlorination and the application of Cl₂ to oyster beds and sewage effluents are discussed. C. C. RUCHHOFF

New sewage-disposal plant at Kitchener. STANLEY SHUPE. *Can. Eng.* 49, 587-9(1925).—An activated-sludge plant having a capacity of 750,000 gal. per day is described. C. C. RUCHHOFF

Activated sludge plant, Melfort, Sask. J. E. UNDERWOOD. *Can. Eng.* 49, 627-9 (1925).—Features and advantages of this small plant are described. C. C. R.

Sewage-disposal plant, York Township. E. M. PROCTOR. *Can. Eng.* 50, 161-1 (1926).—A general description of the new plant. C. C. RUCHHOFF

Recent research in sewage disposal. F. A. DALLYN AND A. V. DELAPORTE. *Can. Eng.* 50, 193-5, 213-5(1926).—The work of the Provincial Expt. Station in Toronto, Canada, on the activated-sludge process is described. C. C. RUCHHOFF

The washing of sewage filtering media. H. MACLEAN WILSON AND J. H. GARNEK. *Surveyor* 68, 383-4(1925).—The cost of washing, sizing and returning old filter bed (contact) material is usually less than the purchase of new material. Washing by machinery except under special conditions is cheaper than hand washing. R. E. GREENFIELD

Recent experiments in dewatering sewage sludge. H. D. BELL. *Surveyor* 69, 79-82(1926).—The use of sand with smooth grains in sludge drying beds causes sludge to dewater more rapidly. Fresh lime-treated sludge dewatered better than unlimed sludge. R. E. GREENFIELD

Anaerobes in sewage. F. E. GREER. *Am. J. Pub. Health* 15, 860(1925).—*Cl. welchii* is the most common anaerobe found in sewage. In order of importance, *Cl. sporogenes*, *Cl. tetani* and *Vibrio septique* were found. Activated-sludge treatment does not materially reduce the number of anaerobes. K. C. BEESON

Sewerage of towns on tidal waters. D. BALFOUR. *J. Royal Sanit. Inst.* 46, 159-60(1925).—The proper placing of the outfall sewers is of importance and varies with local conditions. Proper preliminary treatment should be used to prevent nuisances. R. E. GREENFIELD

Sludge disposal. P. G. LLOYD. *Surveyor* 68, 447, 576-7(1925).—The most economical disposition of sewage sludge depends to a considerable extent on local conditions. R. E. GREENFIELD

Activated sludge experiments at Bradford. J. H. REDDIE. *Surveyor* 68, 451-2, 475(1925).—A loss of 8.3% of the total incoming nitrogen is reported in an activated-sludge plant. The loss is accompanied by a conversion of free NH_3 and nitrate N to org. N. A partial treatment with activated sludge followed by filter-bed treatment is recommended. R. E. GREENFIELD

Water Sterilization by Gaseous Chlorine. London: The Paterson Engineering Co., Ltd.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Soil acidity. E. KURCKMANN. *Z. Pflanzenernähr. Düngung* 5A, 1-92(1925).—The nature and occurrence of soil acidity are discussed, and methods for the determination of acidity and lime requirement are examined practically. In the light of the classification of acidity into 3 forms: "active," "exchange" and hydrolytic (Kappen), variations in soil acidity due to origin, position, moisture and humus content are examined and recorded. B. C. A

Second report on the influence of soil, season and fertilizing on the quality and growth of barley, as indicated by the malts made therefrom. H. M. LANCASTER. *J. Inst. Brewing* 31, 104-11(1925).—The results obtained with barleys of the 1923 season (cf. Russell, C. A. 19, 1748) are as follows: The market value of each barley and the "actual" value deduced from the resulting malt were not influenced by the different kinds of fertilizers employed nor by the soil and the season. The yield per acre was influenced by the fertilizers added. In 1 case especially by the addition of K and NH_4Cl .

in place of the resp. sulfates, there was marked improvement. H. L. HIND. *Ibid* 111-4.—The results of analysis are given. B. C. A.

Action of limestones, marls and certain calcium and magnesium compounds on soil. A. GEHRING AND C. SCHÜLCKE. *Z. Pflanzenernähr. Düngung* 4B, 113-39(1925).—The effects of a no. of limestone samples on the permeability to water, the CO_2 production and bacterial numbers of a soil were much more marked for material passing a 1-mm. sieve than for coarser material, and were in general agreement with the solubilities of the samples in carbonic acid, NH_4Cl and citric acid solns. On a "black" soil the oxide, carbonate and sulfate of Ca had a temporary depressing effect and the corresponding compds. of Mg a more marked and more persistent depressing effect. B. C. A.

Anomalous flocculation in colloidal clays and soils. F. HARDY. *J. Phys. Chem.* 30, 254-65(1926).—Unlike hydroxides of the alkali metals and NH_4 , $\text{Ca}(\text{OH})_2$ flocculates negatively charged colloidal clay quite rapidly. The flocculation phenomena of lateritic clays and soils are discussed from the point of view of Comber's theory, which ascribes the anomalous flocculation of clay by lime to the formation of insol. colloidal complexes. Hydrous Al_2O_3 and Fe_2O_3 which probably occur in laterites are assumed to be colloidal ampholytes possessing isoelec. points not far from neutrality. This assumption serves to explain the mechanism of their anomalous flocculation by lime, silicate ion and phosphate ion. It is also suggested that hydrous SiO_2 , aluminosilicates, and ferrosilicates may be regarded as ampholytes. HARRY B. WEISER

From what depth in the soil can plants usefully obtain nutrients? O. LEMMER-MANN, H. WIESSMANN AND K. ECKL. *Z. Pflanzenernähr. Düngung* 4B, 233-41(1925).—Various crops were grown in deep pots, dicalcium phosphate being added to the soil at various depths down to 75-100 cm. from the surface. In other series different depths of a poor soil were superimposed on different depths of a rich soil and *vice versa*. The crops were weighed and analyzed. The general conclusion is reached that plants can take up nutrients in amts. sufficient to affect the yield from a considerable depth; and that the food supply in the subsoil cannot be ignored in plant nutrition studies. B. C. A.

Hawaii's experience in the use of fertilizer. J. A. VERREY. *Facts about Sugar* 21, 10-3(1926).—The amt. used per acre approx. doubled within 10 years by meeting special soil conditions. Better yield of sugar per acre is due to better understanding of the fertilization problem. T. MARKOVITS

The production of flour of phosphate. E. V. BRITZKE. *Contributions Sci. Inst. Fertilizers (Leningrad)*, *Bull.* 12, 31-40(1924).—This is a description of the tech. milling operations of rock phosphate. J. S. JOFFE

Effect of increased fertilizing on turnips. A. JACOB. *Z. Pflanzenernähr. Düngung* 4B, 156-61(1925).—J. quotes results to show that potash, P_2O_5 or N may be a limiting factor in turnip cultivation. By referring particularly to N and potash it is shown that, up to a limit, a slight excess of the one may overcome a deficiency of the other. Crops treated with a fertilizer contg. potash always show a high yield of dry matter and sugar. This and the cheapness of potash compared with other fertilizers in Germany indicates that a fertilizer with a high potash content is the best for economical cropping of turnips. B. C. A.

Fertilization of cigaret tobacco. A. V. OTRIGANIEV. *Inst. Exptl. Tobacco Culture. Krasnodar (Russia)* 1925, 1-12.—A report of expts. on the effects of fertilizer on yield of tobacco. The fertilizers used were sulfate of potash, acid phosphate and nitrate of soda. In all cases an increase of yield was obtained. J. S. JOFFE

Effectiveness against the San Jose scale of the dry substitutes for liquid lime-sulfur. W. S. ABBOTT, J. J. CULVER AND W. J. MORGAN. U. S. Dept. Agr., *Bull.* 1371, 1-26(1926).—Results obtained in 39 tests with dry calcium-sulfur, 13 with dry sodium-sulfur, and 11 with dry barium-sulfur under practical orchard conditions in 4 states over a period of 3 years showed that the com. samples of dry Ca-, Na- and Ba- sulfur, even when used in strengths much greater than that ordinarily employed, do not furnish a satisfactory control of the San Jose scale. The lack of effectiveness of the dry substitutes is thought to be due to their relatively lower content of the higher polysulfides and to the presence of a higher proportion of CaS_2O_3 , S and other ingredients of no practical value. W. H. ROSS

Methods of stimulating germination of western-pine seed. J. A. LARSEN. *J. Agr. Research* 31, 889-99(1925).—The delayed germination of western white-pine seed is not caused by any inherent physiological characteristic of the seed embryo or endosperm, such as after-ripening or the need for a period of rest, but by the impermeability of the seed coat. Prompt germination may be obtained from unimpaired fresh seed by (1) reduction of the seed coat by chem. corrosion, preferably by immersion

for 45 min. in concd. H_2SO_4 with thorough rinsing; (2) reduction of the seed coat by a mechanical abrasion; and (3) soaking the seed in cold water for 24 hrs. and exposing it to air freezing in winter for at least 40 days.

W. H. ROSS

Arsenic; with special reference to its use in horticulture and agriculture. A. McCUTCHEON. *Pharm. J.* 116, 109-12; *Chemist & Druggist* 104, 161(1926).—After an historical review on As compds., the use of As in horticulture, arsenical weed killers, sheep dips, the use of Paris green as an insecticide, etc., are discussed in order to show the futility and the risks involved in the use of As for these purposes. In sheep dipping, cresol dips have largely replaced As. In discussion, P. F. Kendall refers to the root of *Derris elliptica* as also being used in the prepn. of sheep dip.

S. WALDBOTT

Arsenic in horticulture and agriculture. J. JACK. *Pharm. J.* 116, 112-3; *Chemist & Druggist* 104, 161(1926).—Details are given notably as to the proper time for the successful spraying of fruit trees with Paris green. The harmful effect of As in sheep dips is pointed out. A certain New Zealand sheep dip consists of tar acid (crude PhOH) 29, paraffin oil 36, soft soap 17.5, H_2O 9.5, lanolin 8%.

S. WALDBOTT

Benzene as a larvicide for screw worms. D. C. PARMAN. *J. Agr. Research* 31, 885-8(1925).— C_6H_6 when properly used is an effective larvicide for the screw worm. It has no ill effects on the wounds and acts as a styptic temporarily to make the wound less attractive to the adult flies. When used in wounds as a larvicide for the screw worm it has not been found to be toxic to any animal.

W. H. ROSS

The determination of ρ_{H} [in soil] (HETTERSCHIJ, HUDIG) 2. The purposes and aims of agricultural chemical analysis (BROWNE) 7.

WILEY, HARVEY W.: **Principles and Practice of Agricultural Analysis.** Vol. I—Soils. 3rd ed., revised and enlarged. Easton, Pa.: The Chemical Pub. Co. 685 pp. \$7.50. Reviewed in *Ind. Eng. Chem.* 18, 325; *Chem. News* 132, 44(1926).

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Detection of methanol in alcoholic beverages. F. R. GEORGIA AND RITA MORALES. *Ind. Eng. Chem.* 18, 304-7(1926).—The methods for detg. MeOH in presence of $\text{C}_2\text{H}_5\text{OH}$ were tested and found unsatisfactory. A new method, based on that of Chapin, using KMnO_4 and H_3PO_4 was developed. The excess KMnO_4 is destroyed by the addn. of $\text{C}_2\text{H}_2\text{O}_4$ in H_2SO_4 . A modified Schiff's reagent is then added to the soln. and the characteristic color for HCHO develops after standing 10 min. Methods for the removal of any HCHO existing in the soln. to be tested are described. A list of substances interfering with the test, such as pectin, is given and methods for their removal are discussed.

C. N. FREY

Rapid determination of the gases dissolved in beer and other colloidal liquids. H. D. MURRAY. *J. Inst. Brewing* 31, 137-9(1925).—An app. for detg. gases in beer or other liquids is described and illustrated. The error due to the gas left dissolved in the liquid, such as CO_2 , O and N, in equil. with the evolved gas should be less than 1%.

B. C. A.

Tannins in the wine industry. F. LEVALLOIS. *Ann. fals.* 19, 15-28(1926).—A discussion of the advisability of regulating the nature of such products when used in wine making, with a critical review of the methods of qual. and quant. analysis available for the enforcements of such regulations, if enacted.

A. P.-C

Effect of sunstroke on the ripening of grapes and the composition of the wine made from them. E. HUGUES AND (MISS) PUJO. *Ann. fals.* 19, 40-3(1926).—Comparative analyses of the musts of grapes which had been damaged by excessive solar heat and of neighboring grapes which had been unaffected gave: reducing sugars (as sucrose) 115, 164; total acidity (as tartaric acid) 11.25, 9.00 g. per l., resp., showing that the damaged grapes had not ripened to the same extent as the others. The compn. of the 2 wines is given, the chief characteristics being lower alc. (about 3%), lighter color and higher acidity of the wine from the damaged grapes.

A. P.-C

• **Oxidizability of iron contained in some wines.** JULES WOLFF AND LUCIEN GRAND-CHAMP. *Compt. rend.* 181, 939-41(1925).—The ferrous salts, which wines normally contain, may be transformed rapidly into ferric salts under the influence of an oxidase. This appears to lead to the phenomenon of casse in the wine, a fact hitherto not recognized.

L. W. RIGGS

Addition of hops in the mash tub. J. RAUX. *Brasserie et malterie* 15, 326-30 (1926); cf. *C. A.* 19, 2861.—Two cases taken from brewing practice are described and discussed, confirming previously reported conclusions that addn. of the hops in the mash tub frequently injuriously affects the foaming qualities and mellowness of the beer and that it leads to an increase rather than to a decrease in the amt. of hops required to give character to the beer. A. PAPINEAU-COUTURE

Infection before the boiling stage [in brewing]. R. R. MORITZ. *J. Inst. Brewing* 31, 139-41 (1925).—Various experiences quoted show that decomposed wort-deposits in brewing plant used prior to the boiling stage constitute predigested and highly assimilable food for hostile organisms invading the wort or beer subsequently. Decompn. of such deposits is more rapid than that of post-boiling deposits, as they are unhopped and contain bacteria and yeasts from the exterior of the malt. B. C. A.

Removal of nitrogen from wort by yeast during brewery fermentation. H. F. E. HULTON AND J. L. BAKER. *J. Inst. Brewing* 31, 185-97 (1925).—Data obtained from 14 beers of different original gravities and different types show that neither the protein content of the unfermented wort nor the amt. of residual assimilable protein in the beer can be correlated with the development of acid-forming bacteria or wild yeasts observable either during the subsequent forcing of the beer or under the ordinary trade conditions. In discussion, H. L. HIND pointed out that the authors' figures appeared to indicate that in the case of ales of a given range of original gravity the degree of attenuation and the degree of stability followed the same order. B. C. A.

Application of chemistry to pot still distillation. S. H. HASTIE. *J. Inst. Brewing* 31, 198-215 (1925).—The increased yields of spirit obtained when various salts are added to the water used for mashing result principally from alteration in the p_H value of the mash, this being the predominant factor. The changes in the compn. of the spirit produced by altering the manner of collection of the different fractions are slight but definite. Thus, the effect of early change from foreshot to spirits gives more higher alcs., more acids, more esters, more aldehydes and less furfuraldehyde in the spirit, whereas delayed change to feints from spirit gives less aldehydes, more esters, more acids, more furfuraldehyde and less higher alc. in the spirit. As was shown by Schidrowitz and Kaye (*J. Inst. Brewing* 12, 486-511 (1906)), the simple distn. of low wines, etc., gives rise to changes in the amts. of the constituents in spirit, with elimination of impurities *via* the spent lees and H. finds that the process of distn. of the low wines and feints in the spirit still is accompanied by hydrolysis of the esters, by oxidation of the alc. to aldehyde and also to AcOH by production of esters, etc. As regards the simultaneous formation and hydrolysis of esters, no equil. point is reached in the conditions of practical distn., on account of the continual removal of the interacting substances to the distillate. Many numerical data are given. B. C. A.

Pickle fermentation. F. W. TANNER. *Canning Age* 1926, 121-3.—The process of acid fermentation, the changes in the cucumbers and the microbiology of brine pickles are discussed. T. MARKOVITS

ALLEN, PAUL W.: **Industrial Fermentations.** New York: The Chemical Catalog Co., Inc. 421 pp. \$5.00. Reviewed in *Ind. Eng. Chem.* 18, 326 (1926).

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Review of therapeutic novelties, including specialties and secret remedies, for 1925. S. RABOW. *Chem.-Ztg.* 50, 93-4, 99-100 (1926); cf. *C. A.* 19, 1929. E. J. C.

Opium production in Asia Minor. O. ZEKERT. *Pharm. Monatshefte* 7, 1-5 (1926).—The production areas notably in Persia and Afghanistan are considered and numerous tabulated data given covering the production and export of the commodity for the period 1860 to 1923. W. O. E.

Folia jaborandi. H. ESCHENBRENNER. *Pharm. Ztg.* 70, 1560 (1925); 71, 73 (1926).—Of 3 samples examd. the ash and alkaloidal content were 8.7, 5.8, 5.9 and 0.18, 0.41, 0.35%, resp. Since heat effects partial decompn. in the alk. complex expts. were carried out tending to indicate the most appropriate form of jaborandi prepn. From leaves assaying about 0.76% alkaloid, a decoction, infusion, tea and maceration (all 1:10), a maceration with NH_3 addn., tincture (1 + 5) and fluid ext. (1 = 1) assayed 0.026, 0.036, 0.037, 0.054, 0.056, 0.12 and 0.68%, resp. W. O. E.

Disintegration of pills prepared with "cenomassa" and other constituents. JOHN GRÖNBERG. *Pharm. Ztg.* 71, 55-7 (1926).—A series of expts. is described relative

to the effect of hot H_2O , 2% HCl , 0.4% Na_2CO_3 soln., solns. of pepsin, HCl and H_2O and of trypsin, Na_2CO_3 and H_2O , resp., on the disintegration of various pill mass combinations. The use of orris root, mucilage, lanolin, vaseline, burnt magnesia, wax and collodion is discouraged, while that of "cenomassa" (a mixt. of yeast and yeast ext.) is strongly recommended as a pill or tablet constituent. W. O. E.

Results of investigation of remedies, patent medicines, cosmetics and similar products. C. GRIEBEL. *Z. Nahr. Genussm.* 50, 374-8(1925).—A report of ingredients found in various German proprietaries. WILLIAM J. HUSA

Indigenous and tropical medicinal plants. C. INVERNI. *Boll. chim. farm.* 64, 738-48(1925).—A list of Italian plants having the same pharmacol. action as the pharmacopoeial vegetable drugs. MARY JACOBSEN

Further researches on the preservation of insulin. E. TROCELLO AND A. CRUTO. *J. Trop. Med.* 29, 1-2(1926).—"Insulin should be kept in solid form because, as shown by expts., it does not undergo any alteration at a high temp., and can be preserved for an unlimited length of time. The cause of the difference in preservation of insulin in liquid form lies in the fact that hydrolysis of the product causes a deterioration in its pharmacodynamic properties." FRANCES KRASNOW

Determination of the strength of pituitary extracts by their antidiuretic properties. W. KESTRANEK, H. MOLITOR AND E. P. PICK. *Biochem. Z.* 164, 34-43(1925).—The strength of hypophyseal preps. can be assayed by the antidiuretic effects. Since the antidiuretic activity is parallel to the property of causing contraction of the uterus, results obtained by both these methods yield important quant. information of the therapeutic value of the prepn. The most sensitive method for demonstrating the inhibition of diuresis is on dogs with bladder fistulas. By this procedure, a study of the curve of diuresis reveals also the presence in the prepn. of such impurities as adrenaline or histamine. Another, less sensitive though still quite reliable, method is the detn. of the inhibition of diuresis in rabbits. Vögtlin's acetone dry prepn. is used as the standard with which the activity of other preps. is compared. The uterine method differs from the diuresis method of assaying the strength of pituitary ext. only in the fact that the isolated uterus responds to much smaller concn. of the active material. Commercial preps. tested by the antidiuretic effect reveal as much variability as when tested by the isolated uterus. It is recommended that preps. which have been on the market a year since first put out should be restandardized with preps. contg. coagulable protein or a high albumose concn. should not be permitted for use. Furthermore, the pituitary ext. should be preserved in hard-glass ampules so that the necessary acidity (pH 3-4) would be maintained unaltered over a long time. S. MORGULIS

Spectrographic identification of alkaloids. MAURICE DE LAET. *Ann. nat. légale* 1, 148-58(1921); *Rev. droit pénal criminel. arch. intern. méd. légale* Nos. 3, 4, 5 (March, April, May, 1921).—A series of spectra obtained with light from an arc with Fe electrodes, filtered through solns. of an alkaloid of const. concn. but increasing thickness, shows a gradual widening of the absorption bands, which is absolutely characteristic for each alkaloid, and which is best represented by Hartley's graphical method. The data required are best obtained by detg. the extinction coeffs. by means of a Hilger spectrophotometer; but a considerable personal element is introduced in the appreciation of identity of shade in comparing the lines. The method is extremely sensitive, and can be used on 0.001-0.00006 N solns. A. PAPINEAU-COUTURE

Terpeneless essential oils. M. VIARD. *Parfums de France* No. 35, 10-2(Jan., 1926).—Brief outline of their prepn. and properties. A. PAPINEAU-COUTURE

Oil of cedar from British East Africa. ÉTABLISSEMENTS A. CHIRIS. *Parfums de France* No. 35, 22(Jan., 1926).—A sample of very dark brownish red oil and a sample of light golden-yellow oil, both of which contained enough crystd. cedrol at ordinary temp. to make a semi-solid mass, had the following consts. resp.: d_{20} 0.9712, 0.968; $[\alpha]_D^{20}$ unreadable, $-38^\circ 30'$; acid no. 1.82, 1.54; ester no. 1.75, 1.4; ester no. after cold for mylation 92.75, 87.5; alcs. (as cedrol) 38.55, 36.27%; both are sol. in 5.3 vol. of 90% alc. The crystals sep'd. by draining the oil m 86° and gave cedrol phenylure than m 106-7°. The samples are oil of *Juniperus procera*, Hochst, which differs from oil of *J. virginiana*, L., by a much higher cedrol content, resulting in higher d . and lower $[\alpha]$. A. PAPINEAU-COUTURE

* **Oils of the chaulmoogric group.** EM. ANDRÉ. *Compt. rend.* 181, 1089-91(1925).—Oils from 3 species of *Hydnocarpus* and from 1 species each of *Tarakogenos*, *Asteristigma*, *Oncoba* and *Carpotroche* gave consts. within the following ranges: d . 0.9217-0.9499, n_D 1.4725-1.4780, rotatory power $+44^\circ$ to $+61^\circ 40'$, m . p. 20.5-41°, sapon. index 183.7-201.0, I index 82.8-106.1. L. W. RIGGS

Evaluation of commercial vanilla oleoresins. J. B. WILSON AND J. W. SALE. *Ind. Eng. Chem.* 18, 283-5 (1926).—Authentic vanilla oleoresins for use as standards were prepd. by extg. 3 varieties of vanilla beans with a suitable solvent and recovering the solvent under reduced pressure. These authentic samples, together with com. vanilla oleoresins, were prepd. in different ways for analysis and the resulting products were subjected to analysis. The significance of the analytical data is discussed and those methods of analysis which proved to be useful in evaluating the com. samples are listed.

Thor Emanuel Ekecrantz. 70 years. ANON. *Svensk Farm. Tids.* 30, 18-20 (1896).—A biographic sketch with photograph of one of Sweden's foremost pharmaceutical chemists.

L. W. RIGGS

A. R. ROSE

Hydrogen-ion concentrations of some injection liquids; influence of sterilization. L. ROY. *J. pharm. chim.* [8], 1, 525-32 (1925).—*Cocaine-HCl* (A) is acid in aq. soln., because of partial hydrolysis into base and HCl. Heating increases acidity and recbly but distinctly saponifies the base, splitting off BzOH and MeOH. Alky. of the glass, and higher temp. of sterilizing accentuate this decompn. With *novocaine* (B), *stovaine* and *atropine sulfate* (cf. Hardy, *C. A.* 16, 4299), the effect of temp. sterilization on p_H is similar to that with A. Solns. of B heated to 100-120° in alk. glass yielded by decompn. BzOH and small quantities of NH_3 . (This was set free by MgO and detd. by absorbing the vapor in Nessler's soln.) On mixing unsterilized solns. of 1% A (p_H 5.20) and 5% dextrose-serum (p_H 6.20), p_H of the mixt. became 4.45. Sterilizing it now for 30 min. at 100°, p_H = 4.20; then for 20 min. at 120°, p_H = 3.90. High acidity in injection liquids may account for occasional accidents in surgical operations; it also lessens the anesthetic power; hence the advantage of neutral or slightly alk. solns. (Régner, *C. A.* 19, 134, 352), which allow the use of much smaller doses.

S. WALDBOTT

G. Bruylants (1850-1925). "G. M." *J. pharm. chim.* [8], 1, 552-4 (1925).—An obituary.

S. WALDBOTT

Arsenical emetics of pyridine, quinoline and some alkaloids. L. DEBUQUET. *J. pharm. chim.* [8], 1, 571-4; 2, 5-13 (1925); cf. Yvon, *C. A.* 4, 2094; 5, 1823.—D. prepd. the emetics of *As* and *pyridine* (A), *quinoline* (B), *strychnine* (C), *codeine* (D), *morphine* (E), *cocaine* (F) and *quinine* (G). To prep. A and B, boil equiv. wts. of $H_2C_4H_4O_6$ and base with H_2O , add the equiv. wt. of As_2O_3 , boil, then cool to crystn. To prep. C, D and E, boil $H_2C_4H_4O_6$ and As_2O_3 with H_2O , then add an equiv. wt. of the alkaloid and boil again. In F, add the cocaine to the acid soln. cooled to 60-70°. Evap. the final soln. to dryness *in vacuo* over H_2SO_4 . In G, quinine slowly dissolves in the cold acid soln. finally warmed to 60°; G crystallizes on cooling. The crude yields in prepg. A to G were, resp. 73.8, 86.8, 81.9, 67.9, 62.6, 91.1 and 44.7%. A, $C_4H_3AsO_6 \cdot C_5H_5N$, soly. in H_2O 9.6% at 15°; $[\alpha]_D^{22} + 18.5^\circ$; if calcd on the (active) group $C_4H_3AsO_6$, $[\alpha]_D + 25.03^\circ$. B, $C_4H_3AsO_6 \cdot C_9H_7N$, soly. in H_2O 4.2%; $[\alpha]_D + 15.83^\circ$; calcd. on $C_4H_3AsO_6$, $+25.03^\circ$. C, $C_4H_3AsO_6 \cdot C_{21}H_{21}N_2O_2 \cdot H_2O$; soly. in H_2O 0.48%; in H_2O-Me_2CO soln., $[\alpha]_D - 6.69^\circ$. D, $C_4H_3AsO_6 \cdot C_{18}H_{21}NO_3$; soly. in H_2O 2.1%; insol in Me_2CO ; $[\alpha]_D^{22} - 67.17^\circ$. E, $C_4H_3AsO_6 \cdot C_{17}H_{19}NO_3 \cdot 2H_2O$; sol. in H_2O ; $[\alpha]_D^{15} 62.01^\circ$; for the anhyd. salt, -66.39° . F, $C_4H_3AsO_6 \cdot C_{17}H_{21}NO_4 + 0.37-0.39\% H_2O$. Soly. in H_2O 21.02%; $[\alpha]_D - 38.77$, varying with concn. G, $(C_4H_3AsO_6)_2 \cdot C_{20}H_{24}N_2O_2 \cdot 2H_2O$; soly. in H_2O (15°) 1.23%; $[\alpha]_D - 98.75^\circ$. The aq. solns. of all these compds. are acid to litmus; this may limit their therapeutic uses. A list of 12 references is given.

S. WALDBOTT

Preparation of amorphous iodobismuthate of quinine and its analysis. M. FRANCOIS AND MLE. L. SEGUIN. *J. pharm. chim.* [8], 2, 59-69 (1925).—The prepn. of the crystd. salt by F. (*C. A.* 16, 3663) is restated. The amorphous salt, official in the Codex, is prepd. similarly except that crystn. is avoided by leaving the ppt. in contact with the mother liquor for only a short time. The process is given in detail, as are also the assay methods for Bi, I and quinine. The compn. of the ppt. is approx. $(BiI_3)_2 \cdot C_{20}H_{24}N_2O_2 \cdot 2HI$.

S. WALDBOTT

Presence of lecithin in fats. E. BOEDTKER. *J. pharm. chim.* [8], 2, 107-13 (1925).—By careful oxidation with excess of fuming HNO_3 and detn. of P B. finds lecithin (L) present in 15 samples of vegetable fats (not in castor oil) and in 11 samples of animal fats. Those richest in A are linseed oil (0.53-0.63%), sunflower and almond oils, butter, whale and cod-liver oils. Linseed oil gave 0.15% of ash, chiefly $Ca_3(PO_4)_2$; still, Ca may not be combined in the oil in this form. A Kjeldahl detn. of N in the oil gave 0.077-0.082% N, which would correspond to 4.5% of A. The larger part of this N must be in the form of an albumin-A compd.; in further support of this, the oil gave a pos. test for S.

The influence of chemical constitution on the odor of mustard oils (DYSON) 11A. The colloid chemistry of Bi and its compounds (KUHN, PIRSCH) 2. Emulsions: their theory and practice (BRYANT) 2. Detection of As in cacao (LÜHRIG) 7. Preparation of benzoic acid (LORGES) 12.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

Saltpeter (KNO_3) production in Germany 200 years ago. FRITZ HILDEBRANDT. *Z. angew. Chem.* 39, 90-2(1926). E. J. C.

Salt pans of South Africa. A. J. PELLING. *J. Chem. Met. Soc. S. Africa* 25, 297-308(1925).—A phase rule study of the brines from the Pretoria and Matzap salt pans. The former contains on the av. NaHCO_3 0.8%, Na_2CO_3 8.2, NaCl 15.5, and H_2O 75.5%. For the recovery of the salt and soda the brine must first be concd. to 17.7% Na_2CO_3 and 15% NaCl . This may be effected by agitating the brine with suitable proportions of the dried salts obtained by solar evapn. or by evapn. of the brine to the required d., followed by cooling to 30° , with agitation, so that the $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$ deposited at 100° re-dissolves while NaCl is pptd. pure. On further cooling to 15° about 61% of the soda crystallizes out as decahydrate; a recovery of over 90% may be effected by adding $1/17$ of its weight of water and cooling to 0° and an almost complete recovery by cooling to -5° . The monohydrate may be obtained pure from the soln. by evapn. at 100° until the clear liquid contains 9% Na_2CO_3 and 23.5% NaCl , the crystals being removed from the hot liquor as they form. An av. brine from the Matzap pan contains Na and Mg chlorides, sulfates and nitrates; for the recovery of MgCO_3 and NaNO_3 from this soln. slaked lime equiv. to the sulfate content is stirred in and the ppt. of gypsum and $\text{Mg}(\text{OH})_2$ is carbonated to obtain a mixt. of Ca and Mg carbonates. The purified brine is treated with more slaked lime, equiv. to the remaining Mg, and the pure $\text{Mg}(\text{OH})_2$ so formed is carbonated. Na_2SO_4 is added to the filtrate to ppt. the lime as gypsum. The soln. is then evapd. until it is just satd. with respect to NaCl and NaNO_3 ; on cooling nitrate alone crystallizes. B. C. A.

The fixation of atmospheric nitrogen. H. C. HETHERINGTON. *J. Chem. Education* 3, 170-6(1926).—General. E. J. C.

Nitrogen fixation in the state of Washington. H. K. BENSON. *Chem. Met. Eng.* 32, 935(1925).—Statistics are given on the quantity of hydroelec. power available for N fixation in the state of Washington. W. H. ROSS

Some factors affecting the fixation of nitrogen as sodium cyanide. E. W. GUERNSEY, J. Y. YEE, J. M. BRAHAM AND M. S. SHERMAN. *Ind. Eng. Chem.* 18, 243-7(1926).—The effects of the following variables on NaCN formation were studied: silica in the charge, CO in the gas, rate of N_2 supply, proportion of Fe catalyst, source of C. F. C. Z.

Note on the properties of active carbon. P. HONIG. *Chem. Weekblad* 23, 66-8 (1926); cf. Nellensteyn C. A. 20, 774.—N.'s expts. on the selective adsorption of graphite and diamond are inadequate. Carboraffin (I) and norite (II) cannot be considered to be elementary C in view of their high H and O content. The aliphatic nature of I and the aromatic of II follow from their mode of prepn. The nature of the oxidation products is not a proof of the constitution, since ash (Fe) and porosity of the C have a considerable influence on the course of the oxidation. M. J.

Activated charcoal. ED. URBAIN. *Recherches et inventions* 7, 65-90(1926).—Description of the properties and com. applications of activated charcoals. A. P.-C.

The adsorption of poisons on charcoals. II. ELIZABETH DINGEMANSE AND ERNST LAQUER. *Biochem. Z.* 160, 407-16(1925).—The comparative adsorptive powers of a no. of com. charcoals for strychnine sulfate, HgCl_2 , morphine, $\text{H}_2\text{C}_2\text{O}_4$ and methylene blue indicated that the new "supra-norite" (C. A. 19, 2729) in all cases was the strongest. F. A. CAJORI

Occurrence and commercial purification of graphite. W. LANDGRAEBER. *Brennstoff-Chem.* 6, 355-6(1925).—Deposits in Europe and N. America are discussed briefly. The most important deposit commercially is in Ceylon, mainly because of its purity and easy workability. Purification of raw graphite was formerly effected by grinding and sieving, which resulted in considerable loss of fines. This is now recovered by flotation methods. J. D. DAVIS

Natural pearls and cultivated pearls. RYZIGER. *Ann. fals.* 19, 5-15(1926).—Description of the structure of natural and of cultivated pearls, and of the various methods of distinguishing between them. A. PAPINEAU-COUTURE

Hydrating lime for bleach manufacture. D. F. RICHARDSON, W. E. EMLEY AND J. M. PORRER. *Chem. Met. Eng.* **32**, 936-7(1925).—A study was made of the properties and keeping quality of bleach prepd. from samples of CaO that had been slaked with varying proportions of water. The results showed that in order to produce an entirely satisfactory product, the amt. of water used in hydrating the CaO should be carefully controlled, and that the best product is obtained when the CaO is slaked with 45 to 50% of its wt. of water. W. H. ROSS

The scientific study of the chemical technology of artificial horn. O. MEIER. *Caoutchouc & gutta-percha* **22**, 12,908-13(1925); **23**, 12, 995-6(1926).—A review, with numerous references, of the chemistry and the manuf. of artificial horn (galalith), including a diagram of the process used at Harburg and at Reickenau. C. C. DAVIS

Preparation of crystalline alkali ferrocyanides from their solutions. NAAMLIOOZE VENNOOTSCHAP STIKSTOFBINDINGSINDUSTRIE "NEDERLAND." Dutch 13,904, Dec., 1925. The soly. of alkali ferrocyanides in water is diminished one-half (between 10° and 50°) on addition of a mixt. of alkali carbonate and hydroxide, e. g., 15.7 g. NaOH and 12.1 g. Na₂CO₃ per 100 g. soln. lower the soly. of Na₄Fe(CN)₆ to only 1.44 g. A rather high end temp. of the crystn. process (30°) is hereby possible, on account of the low dc/dt below 30°. By using appropriate amts. of material and adding metallic iron to the original reaction mixt., the necessary carbonate and hydroxide can be made to be automatically present in the product.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

The glass industry and future development. T. C. MOORSHEAD. *Pottery Gazette (Glass Trade Rev.)* **50**, 1722-6(1925).—A model glass-melting tank which will be built by the research department of the United Glass Bottle Manufacturers, Ltd. The design has many novel features and it is thought that the fuel consumption will be cut in half. P. D. H.

The use of lime in glass. G. O. SMITH. *Glass Ind.* **6**, 271(1925).—Lime is used in making almost all kinds of glass. It imparts smoothness and brilliancy and increases resistance to chem. agents. Increasing the lime increased the fusibility to a certain extent, and tends to prevent cords but also increases the tendency to devitrify. Glass with high lime is hard and brittle and must be annealed more carefully. There is a difference of opinion as to whether limestone or burnt lime should be used. The merits of both are discussed. Also the question of how much lime to use is open. The requirements of different types of machines will det. this. F. G. J.

Glass chipping. WALTER SMITH. *Glass Ind.* **6**, 277(1925).—An ornamental translucent non-transparent glass can be made by chipping. The surface is first sand-blasted and then coated with glue. It is then dried and gradually heated in a gas-fired oven. The glue adheres and shrinks as it dries, finally flaking off and taking a chip of glass with each flake. By repeating the sand blasting and chipping a still more beautiful finish is obtained. F. G. J.

Modern street-lighting glassware. ANON. *Glass Ind.* **6**, 278(1925).—A description of the requirements and the process of manuf. of globes and canopies. F. G. J.

Properties of glass as an industrial material. E. BERGER. *Z. Ver. deut. Ing.* **70**, 37-43, 129-32(1926).—A general consideration of the characteristics and nature of glass is given. With data, mostly previously published, B. compares the phys. properties of glass with those of the common metals at normal temps. and with those of fused salts and amalgams at higher temps. While the variety of glass-forming elements is large, the chem. compn. of a glass must remain within fairly narrow limits to be workable, resistant to the action of water, and slow to crystallize. Röntgen-ray patterns indicate no definite mol. structure of pure glass. The change in complexes in glass during cooling is compared to that taking place in the passage of a colloid sol to a gel. H. F. K.

Continuous batch feeder in successful operation on window glass tank. ANON. *Glass Ind.* **7**, 4(1926).—A device that has been in use for several years at the St. Louis plant of the Mississippi Glass Co. The cullet is mixed with the batch and both are held in a tank or hopper above the dog house. A 6-inch steel pipe leads from it at an

angle of 60°. At the lower end is a sleeve which can be raised or lowered by a chain and counterweight. Raising the sleeve increases the flow of batch to the dog house. A heavy pull is maintained on the tank. Scum formation caused very little trouble. The life of the tank is as long as others where the pull is much less. Distribution of refining is excellent.

Making pyrex glass at Corning Glass Works. S. G. ROBERTS. *The Glass Worker* 45, 15(1925).—A long illustrated descriptive article.

Changes give a tank 75% more glass output on less coal. ANON. *Ceramic Ind.* 5, 520-1(1925).—Changes in design of a glass tank at the Carr-Lowrey Glass Company's plant at Baltimore, Md. increased the capacity from 12 tons of melted glass, with 1½ tons of coal, to 21 tons of melted glass, with 12 tons of coal. The changes were (1) lowering of the crown, 18 inches, (2) lowering of the port, which brought the flame closer to the glass, (3) increasing of port area, which gave a 30% increase of flame area, and (4) increasing of the checker area, about 50%.

Natural gas as fuel in glass furnace stack. J. P. SCHELLHAUS, JR. AND G. J. O'NEILL. *Glass Ind.* 7, 5(1926).—A 44-year-old 12-pot stack has been remodeled to heat with natural gas instead of coal. A single No. 6 Maxon Premix burner is used with 6" gas-air mixt. outlet. At 40 pots of 2200 lbs. each a week, the present rate 8.6 cu. ft. of gas is burned per lb. of glass melted.

Dust counting in the pottery industry with special reference to health consideration. E. L. MIDDLETON. *Trans. Ceram. Soc. (England)* 24, 348-60(1925).—Methods of detg. the amts., sizes and kinds of dust in the air of mines and potteries are given. The Owens app. for dust collection and examn. is described.

The minerals of bentonite and related clays and their physical properties. C. S. ROSS AND E. V. SHANNON. *J. Am. Ceram. Soc.* 9, 77-96(1926).—Bentonite is the result of devitrification and chem. alteration of glassy volcanic ash or tuff. It is commonly composed of montmorillonite but less often of beidellite. It contains no gel colloids and few of the crystal particles are as small as colloid size. It has high adsorptive properties. Such clay minerals resemble micas but are not so variable chemically. Montmorillonite is $(\text{Mg}, \text{Ca})\text{O}, \text{Al}_2\text{O}_3, 5\text{SiO}_2, n\text{H}_2\text{O}$. Beidellite is $\text{Al}_2\text{O}_3.3\text{SiO}_2.n\text{H}_2\text{O}$, where n = about 4 and Al_2O_3 may be partly replaced by Fe_2O_3 . A third micaceous clay mineral is halloysite, $\text{Al}_2\text{O}_3.2\text{SiO}_2.n\text{H}_2\text{O}$. It is all crystalline and has high birefringence.

An ultramicroscopic motion picture study of the relation of colloidal content and plasticity in clays. W. G. FRANCE. *J. Am. Ceram. Soc.* 9, 67-76(1926).—The app. included (1) a Bell and Howell Film Camera, with F 3.5 lens and using 16 mm. Cine Kodak film, (2) a Siedentopf Cardiod Ultramicroscope, (3) arc light with cooling cell etc. The ultramicroscopic motion pictures taken of the colloidal fractions of the suspensions showed marked differences in the four clays studied, the relative order of decreasing plasticity being indicated thus: English china clay, S. Car. kaolin, N. Car. kaolin and semi-flint fire clay. "The results tend to support the idea that a definite relation exists between the colloidal content of a clay and its plasticity."

Elimination of limestone from clay. R. A. HORNING. *J. Am. Ceram. Soc.* 9, 110-3(1926).

Influence of ferric oxide and titanium dioxide on pure clays. A. H. KURCHLER. *J. Am. Ceram. Soc.* 9, 104-13(1926).—On kaolin and fire clays cone fusion tests seem to indicate about 6 or 6½ cones lowering of deformation point with the addn. of 10% Fe_2O_3 , also a lowering of 2-3 cones with the addn. of 5% TiO_2 . On a % basis the fluxing actions of Fe_2O_3 and TiO_2 seem to be about the same. No eutectic was revealed.

Influence of the composition of body and glaze on the physical properties of a true porcelain. P. W. LEE. *J. Am. Ceram. Soc.* 9, 97-103(1926).—Lee aimed to produce a better, true porcelain at cones 10-12. Conclusions: (1) Glaze application is better on jiggered than on cast ware. (2) Warpage is greater in cast ware. (3) For any given body there is a temp. which gives best color. (4) For best working conditions the total of alk. earth fluxes must not be over 1%. Not over 0.4% MgCO_3 must be used to improve color. (5) Vitrification is increased by increasing feldspar or flint or by decreasing clay. (6) Fine grinding of glaze lowers the fusion point but increases tendency to craze. (7) ZnO increases whiteness but decreases translucency and produces rough surface.

Refractories at Mellon Institute. M. C. BOOZE. *Iron Age* 117, 479-81(1926).—A list of publications of the refractories fellowship is included.

Refractories for blast furnaces and coke ovens. M. C. BOOZE. *Blast Furnace & Steel Plant* 14, 86-8(1926).

Use of zirconia as a refractory. R. K. *Rev. chim. ind.* 35, 14-6(1926).—Brief outline of the manuf. of refractory ZrO_2 crucibles. A. PAPINEAU-COUTURE

Electric furnace linings (Hughes) 4.

SEARLE, A. B.: **The Chemistry and Physics of Clays and other Ceramic Materials.** New York: Van Nostrand Co. 695 pp. Reviewed in *Expt. Sta. Record* 52, 811.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Development of portland cement manufacture since the war. PAUL HANSEL. *Z. angew. Chem.* 39, 81-90(1926). E. J. C.

Theory of the setting of hydraulic cements. M. BAYKOFF. *Compt. rend.* 182, 128-9(1926).—B. concludes from expts. that the setting of cement occurs in three successive stages: (1) dissoln. or satn. with sol. matter, (2) colloidalization corresponding to the initial setting, and (3) crystn., during which the gels change to cryst. aggregates and which corresponds to the actual hardening process. P. B. PLACE

Method of testing concrete blocks. H. G. LLOYD. *Engineering* 121, 55(1926).—A new method of detg. the normal consistency of neat cement mixts. is given. A method of prepg. concrete blocks for testing and the results of crushing tests are described. I. B. M.

Bond between concrete and steel. D. A. ABRAMS. Structural Materials Research Lab. *Bull.* 17, 20 pp.; *Proc. Am. Soc. Testing Materials* 25, Pt. II, 256-82(1925).—The investigation deals with the bond between concrete and steel and its relation to reinforced concrete construction. The principal conclusions are: (1) Slipping of a steel bar embedded in concrete begins at a bond stress of 10 to 15% of the compressive strength of the concrete, but considerable additional load is taken before the ultimate bond resistance is reached; (2) bond and compressive strength increase with age from 7 days to 1 year; (3) water-ratio of the concrete affects bond and compressive strength similarly; (4) for very rich mixts. the bond fell off; (5) the use of 4% of the 28-day compressive strength as the working stress in bond for plain bars is satisfactory; (6) crude oil causes a reduction in bond and compressive strength; (7) addn. of hydrated lime decreases compressive strength and bond; (8) the pull-out test is satisfactory for comparative studies of bond. I. B. M.

Manufacture of special tar for road surfacing. CH. AB-DER-HALDEN. *Chimie et industrie* 15, 14-7(1926).—Tar for road surfacing should have the following compn: H_2O 0.1%; distn. test 0-20° < 0.1, 200-70° 10.5, 270-360° 15-25; pitch 60-75%; naphthalene < 0.5%, phenols and cresols < 0.5%. Tar meeting these requirements is best obtained by distn. of crude tar by A.'s process (*C. A.* 16, 1498). It can be applied by charging into sprinkler tanks at 160°, the exhaust from the motor being used to keep the tar hot. A. PAPINEAU-COUTURE

Coal-tar pitches and asphalt as road-building materials. F. MÜLLER. *Gas u. Wasserfach* 69, 52-6(1926).—Discussion of properties of pitches and asphalts and of methods of road construction. W. B. PLUMMER

Nomenclature of roofing papers. RIEHM. *Teer* 24, 40-1(1926).—Criticism of Mallison (*C. A.* 20, 810). W. B. PLUMMER

Testing raw paper and impregnating agents for roofing papers. RIEHM. *Teer* 24, 39-40(1926).—Detn. of the amt. of impregnating agent in papers by repeated extn. with creosote oil and finally with benzene showed about 12% left in the paper. For 5 grades of raw paper the data for a 20 × 20-cm. piece were as follows. Wt. of dry paper 23.8, 18.1, 13.5 g., wt. 2 days after impregnation with pitch-anthracene oil mixt. 162, 134, 114 g., wt. after extn. with creosote and benzene, 26.5, 20.0, 15.0 g., wt. of impregnated paper after 14 days at room temp. exposed to air on all sides, 160.8, 133.0 and 113.2 g. W. B. PLUMMER

Preparing asphalt for roofing-manufacture. R. A. HASTINGS. *Chem. Met. Eng.* 32, 875(1925).—A reducing still 8' × 22' is fired along 1 side with surface-combustion burners. The temp. can be controlled accurately at 400° F. The cost (price and kind of gas not given) of gas is 7% of the total cost of producing a roll of finished roofing. W. F. FARAGHER

Brick and cement containing colloidal silicic acid. NAAMLOOZE VENNOOTSCHAP KUNSTZANDSTEENFABRIEK "ARNOUD." Dutch 13,907, Dec. 15, 1925. Dune or river

sand is treated with steam at 20–25 atm. pressure until the surface of the grains is gel atinized (12–16 hrs.), then pressed in forms or used for the prepn. of mortar. The mass hardens on drying.

Practical results of the newer coal researches. IWAN BOLIN. *Meddel. Sveriges Kem. Ind-kontor.* 8, 95–102(1925).—A brief statement of progress in production of fuel oil from coal by low-temp. distn., direct hydrogenation and treatment with H_2 and CO. A. R. ROSE

Coals in the Union of South Africa. J. KERSTEN. *Rev. universelle mines* 9 [7], 6–26(1926).—A description of the various fields, including the geology, methods of exploitation and analyses of the coals. C. C. DAVIS

The Lancashire Coalfield-Smith Seam. ANON (Dept. Sci. Ind. Research). Fuel Research Bd., *Phys. and Chem. Survey of Natl. Coal Resources* No. 5, 30 pp. (1925).—A description and geological sketch map of the Lancashire Coalfield are given together with diagrammatic cross-section figures of the Smith, Rushy Park and Dandy Seams. These are thin coal seams varying from 19 to $52\frac{1}{2}$ in. in thickness and in some localities are cut into by narrow dirt or by fusain bands. Samples were collected from different sections of each seam and from each seam as a whole. Proximate and ultimate analyses of the samples, analyses of the ash, m. ps. and colors of ash, nature of coke formed by the different samples, and comparative studies of the data are summarized in some 35 tables. Sink and float and coal-washing tests were made with some of the samples. Microscopical examns. were made of the coal from the Smith Seam and 2 pictures of coke formed from this strongly caking coal are given. The volatile matter varied from 36 to 40%, ash usually from 1.4 to 4.3%, though 2 samples gave over 10% ash. The compn. of the ash from different horizons in the seams varied, but the m. ps. were practically const. throughout. N ran about 1.6%, calcd. to dry coal. S content varied from 1.11 to 3.51% except in the Dandy Seam where S was high, 6.37%. As only a small proportion of the S in the Dandy Seam occurs in lenticular form this coal could not be purified to any great extent by ordinary washing. After froth-flotation tests this coal was still too high in S to make metallurgical coke, although the high % ash in fine slack from this seam was greatly reduced by the flotation process. Float-and-sink tests on Atherton District coal showed it could be purified by washing. The calorific values of the samples varied from 13,730 to 14,430 B. t. u. per lb. The practical value of these studies in the future com. development of thin coal seams is emphasized. W. W. HODGE

Influence of moisture on the spontaneous heating of coal. J. D. DAVIS AND J. F. BYRNE. *Ind. Eng. Chem.* 18, 233–6(1925); cf. C. A. 19, 1339.—Bituminous coal dried in an inert atm. or *in vacuo* will invariably heat spontaneously from 70° in O, provided the temp. of drying has not exceeded 140° and the time of drying has not been excessive, since the latter apparently alters the colloidal nature of the coal so as to prevent O adsorption and oxidation. Coals "as received" contg. 2–10% moisture will not heat in dry O, showing instead actual cooling, while in O satd. with H_2O at room temp. the coal at 70° heated with low rates of circulation but cooled slightly at high rates, showing in the above cases the large effect of the latent heat of evapn of the H_2O in the coal. W. B. P.

The oily bitumen and solid bitumen in bituminous coal. H. BROCHE AND T. BAHR. *Brennstoff-Chem.* 6, 349–64(1925).—A critical review of the work of Bone, Pearson and Quarendon (C. A. 18, 2593), in which the solid and not the oily bitumen was found responsible for coke cementing power of coal, contrary to previous findings of Fischer and Broche (C. A. 19, 717, 1767). New exptl. evidence is included to show that the bitumens tested on a coked residue (Bone's method) do not show the same coking tendency (cementation and swelling) as when tested on extd. residues (Fischer's method). It is argued that the logical inert on which to test the extd. bitumens is the extd. coal residue since with this a synthetic substance similar to the original coal is obtained. Furthermore Bone's coking test method differed from that of Fischer and might be expected to yield different results. J. D. DAVIS

Microscopical structure of anthracite. H. G. TURNER. *Trans. Am. Inst. Mining Met. Eng.* 71, 127–48(1925). E. J. C.

Artificial after-drying of peat. G. STADNIKOV, P. MEHL AND W. PUTZLO. *Brennstoff-Chem.* 6, 333–6(1925); cf. C. A. 19, 389.—Artificial drying of peat beyond the air-

dry state (25% H_2O) results in lowering its bitumen content with Fe_2O_3 (Russ. pat. 76,138) loses more rapidly by oxidation uncoagulated peat. This is due to catalytic action of Fe_2O_3 . bath a sample of the former showed 215° and the latter 18 reached 215° . Samples air-dried at room temp. were after-d at room temp. and (b) at temps. up to 150° in air or CO_2 . (a) was 4.1%, the acid no. 32.6 and the iodine no. 49.8. In 3.8% to 1.7% with increasing drying temp., acid no. 43.7 to 62.4 and 1 no. 48.8 to 26.4. Drying in CO_2 gave similar results except that the iodine no. decreased only slightly with increasing temp. of drying. Sapon. nos. of the samples also were detd. Drying in air at elevated temps. both oxidizes and hydrolyzes the peat bitumens; oxidation but not hydrolysis is avoided by drying in CO_2 . J. D. DAVIS

How we utilized the largest output of natural gas on record. H. J. STRUTH. *Natural Gas* 7, No. 1, 4, 5, 62(1926).—The total output of natural gas for the year 1924 was about 1300 billion cu. ft. This natural gas was utilized as follows: industrial consumption 34%; consumption by gas and oil companies for drilling and pumping 27%; domestic consumption 22%; unaccountable loss 12%; converted to gasoline 3%; other uses 2%. The industrial consumption is again subdivided according to the various industries. E. G. MEYER

Measurement of raw gas and its distribution to coolers, washers and purifiers. R. GEIPERT. *Gas u. Wasserfach* 69, 61–3(1926).—Gas is measured and its distribution controlled by the pressure drop across calibrated plate type valves or dampers. W. B. PLUMMER

The corrosion and rusting of wrought iron and steel gas barrel. ALBERT STOKES, et al. Report of the Wrought Iron Tubing Inquiry Committee. *Gas J. (Supplement)* 171, 3–12(1925).—Samples of metal were immersed for definite periods of time in siphon liquor and in distd. water. Results show that the most desirable material is wrought iron of the very best quality without any admixt. of steel. Exposure in a stream of moist coal gas gave the same result. Some samples of material which had given poor service were found to be heterogeneous, a mixt. of wrought iron and steel. Tests carried out in a closed bottle system, with different electrolytes, different gas mixts., in which the samples were subjected to complete immersion, to the action of a film of the electrolyte and to the action of a current of the gas without and with water, gave results from which conclusions were drawn as follows: (1) CO_2 is not an essential agent for oxidation. Its presence to the extent of $2\frac{1}{2}\%$ in a wet gas contg. 1% of O accelerates oxidation about 10%; (2) CO_2 slowly removes Fe in the form of a soln. of $Fe(HCO_3)_2$; (3) liquid water is an essential agent of corrosion. Its effect is more marked when present in small than in large quantities; (4) none of the products of corrosion has a retarding effect upon further corrosion; (5) the relative rates of corrosion are, very pure iron, 100, wrought iron, 150, steel, 190; (6) $(NH_4)_2SO_4$ considerably accelerates the rate of oxidation; (7) the chief agencies of corrosion are O, H_2O and certain compds. of NH_3 ; (8) rust is formed even with wrought iron although more slowly than with steel; (9) troubles from transported oxides are to be avoided by (a) covering internal surfaces with protective coating, (b) removing H_2O completely from the system, and (c) limiting the amt. of O in the finished gas. A. E. GALLOWAY

Absorption of carbon dioxide from gas mixtures containing it by means of water under pressure. C. ZERBE. *Brennstoff-Chem.* 5, 53–6(1924).—After a detailed account of the work of Blair, Wheeler and Reilly (C. A. 17, 3071) Z. describes an attempt to remove completely about 10% of CO_2 contained in a mixt. of CO and H_2 by scrubbing the gas, under a pressure of 150 atm., with water. The attempt was unsuccessful and the quantities of CO and H dissolved by the water were excessive. B. C. A.

Determination of paraffin hydrocarbons in technical gas analysis. H. TROPSCH AND E. DITTRICH. *Brennstoff-Chem.* 5, 325(1924); cf. C. A. 19, 719.—The use of wire-form Cu oxide in the silica combustion tube leads, sooner or later, to the formation of Cu silicate. Lining the tube inside with thin asbestos paper is not altogether satisfactory, but good results are obtained by passing a mixt. of O and the gas to be analyzed through a quartz tube contg. asbestos coated with a small quantity of Cu oxide, the possibility of explosion being eliminated by inserting thin Al wire into the capillaries. B. C. A.

Benzene research. Second report of the Joint Benzole Research Committee. W. H. HOFFERT. *Gas J.* 170, 654–5(1925); cf. C. A. 19, 3009.—*Sulfur in benzene.*—Certain benzene motor spirits had a marked corrosive action on Cu and brass, forming Cu_2S and CuS as a result of the presence of free S. The action on Cu of solns. of free S in pure benzene was studied. Impurities in the benzene tend to prevent corrosion.

of the Cu and the concn. of free S required to cause corrosion depends on the nature and amt. of impurities. The Ormandy and Craven method used for detg. free S in benzene is described. *Active carbon vs. silica gel.*—H. detd. the relative adsorptive capacities of the active carbons and a silica gel by satg. at 20° with a benzene-air mixt. contg. 0.86% by vol. of benzene. Urbain carbon showed 36% by wt. adsorption, coconut charcoal 32%, Bayer T carbon 28% and silica gel 18%. The adsorptive efficiency for each was 98%. C. showed a preferential adsorption for benzene unaffected by H₂O vapor up to the break point. Silica gel removes H₂O vapor quant. and shows a fairly high capacity for benzene. Adsorptive variations with temp. were detd. The adsorptions by wt. of adsorbent were C 15 to 30%, silica gel 8 to 14%; or g./100 cc. adsorbent space, C 5.8 to 11.6 and silica gel 5.7 to 10.0 g. *Active-carbon plants.*—A report of several plants using active C for recovery of benzene is given. A. E. GALLOWAY

Some methods of benzene plant control. Valuation of light oil. R. R. MURRAY. *Gas World* 82, Coking sect., 41-3 (1925).—M. describes a simple method by which the value of a light oil could be stated in its actual content of washable products. A no. of samples collected from works were analyzed and distd. by (1) the ordinary retort method with thermometer $\frac{3}{4}$ in. from the bottom; (2) the Engler distn. flask method. Fractions were cut in 5° stages over the whole boiling range of the oil. The totals of the percentages obtained below 125° corresponded to the percentages of water-white products obtained by washing, the difference varying from 0.3 to 3.6%. By the distn. method up to 125° for detg. the water-white value were found differences between lab. and actual plant yields varying between 0.2 and 5.0% over a period of 1 yr. This method is used in the detn. of the satn. content of benzenized and debenzenized oils. The wash oil is distd. up to 160° and 100 cc. of the distillate distd. up to 125° for the water-white value. To test absorbing oil, a standard absorbing oil was prepd., which could retain its fluidity without an undue proportion of light creosote. According to this method a good absorbing oil should have a small percentage of steamed distillate and the difference in fluidity before and after steaming should be small. The retort test is of no importance as a criterion. A. E. GALLOWAY

The carbonization of solid combustibles at a low temperature. H. VERDINNE. *Rev. universelle mines* 8 [7], 296-306 (1925).—A review and discussion dealing with present developments, with quant. data of yields of primary tar, etc., from various coals, schists, peats and lignites. C. C. DAVIS

Influence of temperature on the coke yield in the crucible coke test. H. STRACH AND CAMILLA MIKA. *Gas. u. Wasserfach* 69, 105-7 (1926).—Detailed tabulated results of tests in which standard procedure was followed (Teclu burner, 7 min. heating, etc.), except for changes in the gas heating value (range of 4050-4210 kg. cal./cu. m.) and in the air supply which gave such variations due to changes in the flame temp. that it is concluded that the test specifications should call for "heating for a period of 7 min. in such fashion that the temp. of the interior of the coke button rapidly reaches a temp. of 900°, at which temp. it is maintained throughout the test period," the temp. being detd. by a thermocouple. W. B. PLUMMER

New coking installations of the Mequin type. ERNST BLAU. *Gas Age-Record* 55, 831-2 (1925). H. G. BERGER

The utilization of waste heat from coke ovens. A. PARKER. *Gas World* 82, Coking sect., 34-8 (1925).—The principal methods of utilizing the available waste heat from coke-oven installations of 3 types (waste heat, recuperative and regenerative) have been considered; and estimates have been made of the amts. of energy which should be recovered from the waste gases, surplus gas and by the dry cooling of coke. The waste heat from coke ovens given in lbs. of steam at 100 lb. pressure (from water at 15°) per ton of coal is: waste-heat oven, 2,195; recuperative oven, 2,104; regenerative oven, 2,126; these are equiv. to 87.8, 84.2 and 85.0 kw.-hrs., resp. The waste heat from coke ovens given as kw.-hrs./ton of coal (surplus gas used in gas engines) is: waste-heat oven, 114.6; recuperative oven, 137.8; regenerative oven, 158.8. The data were obtained from plant operation. A. E. GALLOWAY

The flow of gases in the coke oven. W. FORSTER. *Gas World* 82, Coking sect., 48-52 (1925); cf. Smith, C. A. 19, 3369.—The gas in all cases flows outwards and upwards if the coal is crushed and contains a fair proportion of dust. The coke formation at the top of the oven is so shaped that the gases can be seen coming up the sides of the charge. The pressures in the center of the oven are 2 to 3 in. and are due to the advancing plastic mass rather than to gas evolution. Very little gas is evolved on the inside of the plastic layer as evidenced by the absence of NH₃ in the water and the gas could be lighted only with difficulty. If more than a moderate pressure of gas existed, the porous layer between the plastic layer and the solid coke could not exist. Sufficient

fissures are formed to carry the gases away. This and the porous structure between the plastic layer and coke is the path of travel.

The path of travel of the gases in the coke oven. A. THAU. *Gas World* 82, Coking sect., 59-60(1925).—The path of gases in an oven is inward. A perforated sheet iron box filled with coal was inserted crosswise in the oven. The box was withdrawn at the end of $\frac{1}{4}$ of the coking time and cooled in sand. Photographs show that the coking proceeds inward from the oven wall. Back of the advancing coking seam the fine porous structure of the semicoke with deposited carbon offers greater resistance to the gases than the plastic layer, and the path therefore must be inward.

The flow of gases in the coke oven. G. E. FOXWELL. *Gas World* 82, Coking sect., 56-8, 64-5(1925).—The vol. of gas passing through the coal is not the only factor affecting porosity, but the viscosity of the plastic mass is important and varies with the speed of carbonization. This speed is not the same at the center as against the oven walls. The orientation of the pores is evidence of the direction of flow of gases at the time of solidification of that particular piece of coke, but is no evidence of the path taken by the gases as a whole. The resistance of the plastic layer to the flow of gases depends entirely on the rate at which the coal is carbonized and on the temp. existing in diff. parts of the plastic coal. Contrary to theory, when gas passes through a porous mass the resistance decreases as the temp. increases; this is due to contraction and development of fine cracks in the coke. Only 10% of the volatile matter was evolved during the plastic stage (370-470°). F. discounts observations of Thau (preceding abstract) on cracks formed because they were taken after cooling the coke, and refutes the suggestion that the pore space of coke is too small for the gases to travel through by the statement that the pore space is 40-50% of the coke. A portion of the gases passes through the coal and a portion through the coke. The relative quantity that passes up each path is governed by the resistance. The resistances and area of cross-section of the two paths are not const. The quantity of gas taking each path will vary with the time elapsed since charging the oven, with the nature of the coal, the temp. of the oven, and the amt. of moisture in the coal. The path followed by a particle of gas from the position and at the instant of generation depends on the number and the position in the oven at which other particles are being generated. It also depends on the resistance of the coke, of the plastic layer and of the coal. The resistance of the plastic layer and the relative amts. of gas evolved at diff. portions in the charge are dependent on the nature of the coal and can be detd. in the lab. The value of the knowledge of the path of travel is detd. by the behavior of hydrocarbons under the action of heat and heated surfaces.

The flow of gases in the coke oven. L. H. SENSICLE. *Gas World* 82, Coking sect., 61-3(1925); cf. Smith, C. A. 19, 3369.—The gases pass upward through paths created in the plastic layer. These paths persist but a short time after rigidity has been reached and then become choked with deposited C. The plastic zone is the nucleus of chem. activity in the oven, and the seat of max. evolution of volatile matter. Subsidence in the charge with high-volatile coal and the V shape of the plastic layer are important points for consideration and illustrate the type of variable factor necessary to take into account in formulating a theory for any particular case.

By-product coking in Alabama. F. W. MILLER. *Trans. Am. Inst. Mining Met. Eng.* 71, 1106-11(1925); cf. C. A. 19, 570.

Refractories for blast furnaces and coke ovens (BOOZE) 19. Tables for technical gas calculations (MICHEL) 13. The blue oil of peat tar (Herzenberg, Ruhemann) 10.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Colloids in petroleum and in the petroleum industry. A. E. DUNSTAN, F. B. THOLE AND W. H. THOMAS. *J. Soc. Chem. Ind.* 44, 439-43T(1925).—A general discussion of oil-field and refinery emulsions, sludge in pipe-lines, "tar fog," treating of distillates, fuller's earth, clays, bauxite, vaseline and lubricating greases. No new material is presented.

Portable combustion apparatus for detection and measurement of small quantities of petroleum vapor. C. A. NEUSBAUM, P. L. DE VERTER AND E. W. DEAN. *Ind.*

Eng. Chem. **18**, 183-5(1926).—A convenient, accurate, portable app. that is used particularly for testing the atm. of tanks of ships is described. W. F. FARAGHER

Adsorption studies on the decolorization of mineral oils. T. H. ROGERS, F. V. GRIMM AND N. E. LEMMON. *Ind. Eng. Chem.* **18**, 164-9(1926).—Several oils and adsorbents were used in proving that Freundlich's equation applies accurately when the amt. of substance adsorbed is measured by the loss of color of the sample. *Measurement of color* expressed on a *true color scale* is described. Apparent deviations from the expected behavior are discussed. "Cracked" kerosene becomes colored in the presence of "clay"; the change was proved to be due to an oxidation. W. F. F

Agitation and mixing in petroleum refining. M. J. BURKHARD. *Chem. Met. Eng.* **32**, 860-1(1925).—Continuous treating-plants are discussed generally. A diagrammatic sketch of a plant in which treating-towers are replaced by orifice-tubes is presented. Treating units consist of 2 vertical runs of 4 in. pipe, each contg. 20 orifices. Orifices are 2 in. in diam., are staggered, and are spaced at 12 in. intervals. Settling units are of the usual type. W. F. FARAGHER

The disposal of petroleum foots oil. L. G. MARSH AND L. D. WYANT. *Bur. Mines. Repts. of Investigations* No. 2724, 7 pp.(1926).—Recycling foots oil through the stills, lowers the percentage of wax recovered, as was shown by lab. distns. It appears that half the foots oil could be distd. with steam, and the residue carried through the sweating oven as slack-wax or mixed with new slack-wax. The distillate could be mixed with the wax-distillate. The com. practicability of the process has not been established. The best procedure would be to return foots oil to presses mixed with new wax distillate, pressing first at relatively high temp., then at a lower temp. Gas oil of the new wax-distillate might be increased so that a single pressing of the mixt. would be feasible. W. F. FARAGHER

Oil shale in Santa Barbara County, California. F. D. GORE. *Bull. Am. Assoc. Petroleum Geol.* **8**, 459-72(1924).—The oil shale of California differs both physically and chemically from other shales from other parts of the United States and foreign countries. It is in a truer sense an oil-satd. diatomaceous shale from which oil may be extd. by the use of any well-known solvents such as benzene, CHCl_3 , pyridine, etc. The oil from the shale, when first obtained, has a gravity of about 14°Bé. and is very low in viscosity, bright green in color, which is lost when exposed to sunlight and becomes dark brown with an increase in viscosity. These changes are apparently due to oxidation hastened by the catalytic effect of the high S content of the oil. The removal of these S compds. is the chief difficulty to be met with in refining. Aromatic hydrocarbons constitute the largest percentage of the oil. Tar acids and nitrogenous oil are present in very small quantities. Shale oil readily emulsifies with the water present in the shale during the process of extn., and is more difficult to dehydrate than the ordinary crude petroleum. C. I. C

Asphalt and related bitumens in 1924. K. W. COTTRELL. *U. S. Geol. Survey. Mineral Resources of U. S. 1924*, Pt. II, 161-9(preprint No. 14, publ. Jan. 18, 1926). E. I. C

Melting point determination of asphalt. I. J. LAGERQUIST AND M. FREDMAN. *Svensk Kem. Tids.* **37**, 266-76(1925).—In the detn. of the m. p. of asphalt, differences in rate of increase in temp. in inner diam. of the tube and in thickness of the walls caused marked differences in results. These factors should be agreed upon and closely adhered to. Some of the deviations which do not affect the readings are the time interval between fixing the tube and the detn. and rate of cooling of the tube after it has been fitted. A. R. ROSE

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Testing explosives in experimental galleries for safety in fire damp and coal dust. M. LUPUS. *Z. ges. Schiess-Sprengstoffw.* **20**, 40-2(1925).—L. discusses the possible relation of brisance of an explosive to safety of the explosive in gas and dust. A blown-out shot, such as is produced in the gallery, causes an adiabatic compression which may raise the temp. of the gas high enough for its explosion. 550 g. of the explosive Car-bonite in 55-mm. cartridges fired in a 55-mm. hole, and 150 g. of the same explosive in 40-mm. cartridges fired in a 40-mm. hole, were sufficient to cause explosion in the gallery. The pressure per cm.^2 of bore hole area is practically the same in each case.

A gas explosion results from the compression of the gases from the explosive charge, even when no coal gas or dust is present in the gallery. Gas explosions may result from the high flame temp. of a slow explosive or from the high compression produced by a brisant explosive. Factors influencing the probability of explosion are the brisance and wt. of charge of explosive, length of tamping in proportion to explosive charge depth and diam. of bore hole.

C. G. STORM

Chemistry of the Nathan-Thomson-Rintoul process. R. K. VICTOR AND H. JANOS. *Z. ges. Schiess-Sprengstoffw.* 20, 89-91, 98-100(1925).—As a result of an extensive series of expts., the results of which are tabulated, it is concluded that the prevention of after-sepn. of nitroglycerin from the spent nitrating acid by the addn. of small quantities of H_2O (5%) is not to be attributed to increase in soly. of the nitrated product in the dild. acid, but that the phenomenon is more probably associated with oxidation processes.

C. G. STORM

Chlorate and perchlorate explosives. E. SPITALSKY AND E. KRAUSE. *Z. ges. Schiess-Sprengstoffw.* 20, 103-7, 119-23, 133-5(1925).—A study was made of the influence of increasing d. of various chlorate and perchlorate explosives on their brisance, and also of the effect of variations in the nature of the combustible ingredient on the explosive strength at the optimum d. of loading. The Pb-block compression test was used as the measure of brisance. Five definite methods of packing the explosives were used in order to obtain densities ranging from those of loosely filled cartridges to those of cartridges packed by hand compression in 10 sep. increments. Mixts. of 88 to 90% of $KClO_3$ with 12 to 10% of org. materials were tested to det. the effect of such variations in d. of the cartridges on the brisance. Different mixts. of paraffin, vaseline, asphalt, wax and rosin were used as the org. material. The effect of increased d. varied greatly with the compn. of the org. material. With some mixts. the max. brisance was obtained when the explosive was entirely uncompressed; with others, only when strong compression was used. Corresponding mixts. with $NaClO_3$ and NH_4ClO_4 showed higher brisance and much less effect of increased d. than the $KClO_3$ mixts. The optimum densities for max. brisance were for $KClO_3$ 1.15, for $NaClO_3$ 1.40 and for NH_4ClO_4 1.20. Whereas 90% $NaClO_3$ and 10% of a mixt. contg. 5% vaseline, 2.5% rosin and 92.5% paraffin is a strong explosive 90% $KClO_3$ and 10% of the same mixt. could not be exploded with the same strength of detonators. Each individual chlorate or perchlorate requires a particular compn. of org. material in order to make its energy properly available. At low d. of loading the proportion of org. material to oxidizing agent may vary over a wide range without appreciable effect on brisance. At higher d. the brisance is decreased by increasing the org. material so that a deficiency of O results. This effect is much more pronounced with $NaClO_3$ than with NH_4ClO_4 . As a result of their investigations the authors have developed the following compns. possessing highly satisfactory explosive properties:

	I	II	III
Oxidizing agent	$KClO_3$ 88%	$NaClO_3$ 90%	NH_4ClO_4 89%
Organic material	12	10	11
Compn. of org. material	{ Vaseline 5	5	8
	{ Paraffin 30	92.5	27
	{ Rosin 65	2.5	65

These explosives, designated "Almatrites," are less sensitive to friction than the Cheddites. The results of various chem. and phys. tests are given in detail.

C. G. S.

Measurement of pressures developed in closed vessels by the combustion of powder.

E. BURLLOT. *Mem. poud.* 21, 403-10(1924).

TENNEY L. DAVIS

Experimental determination of force and covolume of explosives. E. BURLLOT.

Mem. poud. 21, 411-90(1924).

TENNEY L. DAVIS

Utilization of heat in the stabilizing boiling of nitrocellulose. H. CARRIÈRE.

Mem. poud. 21, 491-3(1924).—The changes which occur during the stabilization of 1 kg. CP_1 (nitrocellulose of 13.4% N) absorb about 600 large cals. or about $\frac{1}{4}$ of all the heat supplied for the boiling treatment. CP_2 (12% N) correspondingly absorbs about 400 large cals. per kg., or about $\frac{1}{3}$ of the total heat supplied for the boiling treatment.

TENNEY L. DAVIS

Deflagration products of smokeless powder. H. C. KNIGHT AND D. C. WALTON.

Ind. Eng. Chem. 18, 287-91(1926).—Following the explosion of smokeless powder on the U. S. S. Trenton (cf. Bloch, C. A. 20, 823) this investigation has been made on the compn. and physiol. effects of the gases produced under conditions similar to those obtaining in the turret of that vessel. The development of notable quantities of CO and "nitrous

gases" was positively shown and malignant physiol. effects of these gases were demonstrated.

CHARLES E. MUNROE

The rate of detonation of mercury fulminate and its mixtures with potassium chlorate. L. R. CARL. *Army Ordnance* 6, 302-4(1926).—From the data obtained it is concluded that (1) the rate of detonation of Hg fulminate is a straight-line function of the d.; (2) the increase in rate due to increased d. is most rapid with the 80/20 mixt. and least with straight fulminate; (3) this limited no. of tests seem to show that additional confinement has no noticeable effect on the rate of the 80/20 mixt., while the rates of the 90/10 mixt. and the straight fulminate are very appreciably increased.

CHARLES E. MUNROE

Comparative tests on French pyroxylin sporting powders T and M and on the reputedly best foreign powders. MAURICE PORCHÉ. *Mem. poud.* 21, 133-43(1924).—French powders T and M gave about the same pressures and dispersions as English E. C. no. 3, Empire Nobel, Schultze, Nobel Ballistite, Normale, and Smokeless Diamond. Italian Acapina, German Trotschwill and Troisdorff, and Belgian Coopall no. 2 and Mullerite, but powder T gave the smallest variations of velocity and would, therefore, be expected to give the most regular penetration.

TENNEY L. DAVIS

The determination of sulfates in gun cotton. H. B. DUNNICLIFF. *Analyst* 50, 543-7(1925).—Heat 5 g. of material on a water bath with 50 cc. of concd. HNO_3 until dissolved. Cool, add 1 g. of NaClO_3 , evap. on a sand bath and heat the residue for 30 min. in an air oven at 120° . Treat with 20 cc. of HCl and 0.5 g. NaClO_3 and repeat the above evapn. and heating. Heat the residue with 0.5 g. of NaClO_3 and 20 cc. of concd. HNO_3 . Evap. on the sand bath, again heat at 120° and repeat with NaClO_3 and HCl . Dissolve the final residue in water contg. 1 cc. of HCl , boil, filter and ppt. BaSO_4 in the usual way. Run a blank, following the same procedure without any gun cotton.

L. A. OLNEY

New dyes and sample cards. PAUL KRAIS. *Z. angew. Chem.* 39, 143-6(1926).

E. J. C.

New dye intermediates—2,4-diaminophenyl oxide, 2-nitro-4-aminophenyl oxide and 2,4-diaminophenyl sulfide. M. T. BOGERT and R. L. EVANS. *Ind. Eng. Chem.* 18, 299-302(1926).—2,4-Dinitrophenyl oxide has been reduced successfully both to the 2-nitro-4-aminophenyl oxide and to the diamine. 2,4-Dinitro- and diaminophenyl sulfide have been prepd. from 2,4-dinitrochlorobenzene and their properties studied. From these derivs. of *m*-nitroaniline and *m*-phenylenediamine azo dyes have been produced by the usual methods.

L. W. RIGGS

Effect of variation in concentration of dyes in solution upon their quantitative determination by spectrophotometry. Methylene blue. R. W. FRENCH. *Ind. Eng. Chem.* 18, 298-9(1926).—The effect of variations in the concn. of the dye in soln. was studied with methylene blue. Variations within the customary limits used in this kind of detn., that is, 2 to 10 parts of dye per million of solvent, have a very appreciable effect on the values of the extinction coeff. This effect must be considered in spectrophotometric work. It is suggested that the use of alc. as a solvent would avoid such effects.

L. W. RIGGS

Causes of uneven dyeing of rayon. R. H. TIBA 4, 101, 103(1926).—Brief review with bibliography of 10 references.

A. PAPINEAU-COUTURE

New method of testing rayon, and textiles in general. ETIENNE BURLET. *Rev. textile* 23, 1135(1925).—Because of the variations in the normal H_2O contents of different kinds of rayon under various atm. conditions, B. suggests replacing the detn. of total H_2O by detn. of wt. when in equil. with atm. H_2O under given temp. and humidity conditions.

E. J. C.

The wetting capacity of some textile preparations. W. HERBIG and H. SEYFERTH. *Z. deut. Oel-Fett-Ind.* 45, 751-5(1925).—Mako-cotton yarn of 1 m. length in the form of skeins of 11-12 cm. was immersed in the test liquor, centrifuged and weighed, all under standard conditions. Five com. preps. were tested. The wetting capacity increases with the concn. to a certain limit, but varies with each liquor according to its concn. The plotted curves are steep to a mean concn. of about 10 g. per l. and then

become horizontal. Evaluation by the wetting capacity alone furnishes insufficient data for practical purposes; it is necessary to include the price in the diagrams to show the % of wetting obtained per money unit. Evaluation of wetting power on the basis of surface tension by means of the stalagmometer furnishes results which are at variance with factory experience.

Retting with urea. O. FLIEG. *Faserforschung* 4, 131-41 (1924).—At a retting temp. of 27-30° a concn. of 0.25% of urea accelerates the process and eliminates the foul smell as well as larger amts., and the liquor becomes less acid than in the absence of urea. The product has a better feel and the fibers are better sepd. than after a normal ret and the waste liquor is an excellent fertilizer.

P. ESCHER

B. C. A.

The significance of a definite regulation of atmospheric moisture in the textile industry. JULIUS OBERMILLER. *Z. angew. Chem.* 39, 46-51 (1926); cf. *C. A.* 19, 897.—The regulation of the moisture in the air is very important in the textile industry. In dyeing processes, large quantities of moisture are given off and frequently must be removed, to prevent harm to the thread in other stages of the process. In the spinning and weaving industries, a certain amt. of humidity is essential to prevent the thread from becoming brittle and to prevent the accumulation of too heavy charges of static electricity. The lower limit of relative humidity required in general is about 50%, although this is higher with increasing fineness of the work, in some cases being as high as 80-85%. Curves are shown in which the moisture content of various types of thread is plotted against the relative humidity of the amt. at 20°. From 10 to 75%, the curves are approx. straight lines, but above 75% the H₂O content rises rapidly. Thus the H₂O content is 1.8% for wool (1), 2.5% for artificial silk (2), 2.0% for raw silk (3), 1.8% for degummed silk (4), and 1.3% for cotton (5) at 2.5% relative humidity. At 35.0% relative humidity, H₂O content is 11.0% for (1), 8.5% for (2), 8.0% for (3), 7.3% for (4), and 5.5% for (5). At 75.0% relative humidity, H₂O content is 18.5% for (1), 17.5% for (2), 15.5% for (3), 13.5% for (4), and 11.0% for (5). For 100% relative humidity, H₂O content is >32.0% for (1), >40.0% for (2), >35.0% for (3), >35.0% for (4), >26.0% for (5). With increase in temp. from 20° to 25°, the H₂O content of the fiber at 75% atm. moisture decreases as follows: for wool it drops from 17.6 to 17.4%, for raw silk from 15.0 to 14.25%, for degummed silk from 13.35 to 12.7%, for American cotton from 9.5 to 9.35%, and for Indian cotton from 10.06 to 9.85%. The variation of strength with H₂O content is detd. by measuring tensile strength before and after immersion in H₂O. The results are as follows and are expressed in % of strength in the dry condition: cotton 110-120, wool 80-90, silk 75-85, acetate silk 65-70, Cu silk 50-60, viscose silk 45-55, nitro silk 30-40.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Lead as raw material for the pigment industry. K. HARTMANN. *Farbe und Lack* 1925, 618-9.—A brief review of production data, of the smelting of Pb ores, of the common Pb salts and pigments, of attempts to prohibit the use of paints contg. Pb pigments, etc.

F. A. WERTZ

Practical plans for paint plants. GEO. SUTHERLAND. *Paint, Oil & Chem. Rev.* 81, No. 8, 12-4 (1926).—The design and layout of paint and varnish factories are discussed.

E. J. C.

The shading of the mineral colors. HUGO KÜHL. *Farbe und Lack* 1925, 617.—The various occurring shades of pigments of the same chem. compn. are due not only to variations in the size of the pigment particles, but perhaps also to the state of aggregation of the mols. Fe oxides, Pb chromates, and other pigments which occur in several different shades are reviewed briefly. F. A. WERTZ

Physical tests on lacquers. H. A. GARDNER AND H. C. PARKS. Paint Manufacturers Assoc. of U. S., *Circ.* No. 253, 174-94(1925).—Hot and cold H₂O immersion, bending, tensile strength and elongation, exposure tests, etc., give valuable information on the usefulness of lacquer films. Results of such physical tests on a number of lacquers of various compns are tabulated and given in detail. Illus. F. A. WERTZ

Corrosion in the works. C. O. HARVEY. *Chemistry & Industry* 44, 110-1(1925).—An excellent paint to prevent corrosion in chem. plants is made as follows: Treat coal tar with 10% CaO, heat gradually to 200°, maintain this temp. 15 min., add 4 lb. per gal. tar of a hard bituminous such as gilsonite, heat until homogeneous, cool to about 90°, and gradually stir in 1 vol. of crude benzene to 2 vol. of the molten mixt. F. H

Corrosion in the works. A. G. BYARD. *Chemistry & Industry* 45, 24(1926).—The crude C₆H₆ used in making the rust-inhibitive bituminous paints recommended by Harvey (preceding abstract) must be absolutely free from phenols and related substances, the mixing temp. must not be over 80°, and the tar should have the upper limit of d. 1.175, with as low a free C content as possible. Linseed-oil paints should never be used over bituminous paints, but the reverse practice has given excellent results with red lead coats that have been allowed to dry thoroughly. F. A. WERTZ

The isomerism of Guignet's green, a phenomenon of the particle size. VON LOTHAR WÖHLER AND J. DIERKSEN. *Z. angew. Chem.* 39, 13-6(1926).—It was previously shown (*C. A.* 2, 2765) that boric acid is not an essential constituent of Guignet's green, which appears to be 2Cr₂O₃·3H₂O; but a further study shows that the brilliant Guignet's green differs from the dull green Cr oxide hydrates in that it has undergone an increase in particle size. The role played by boric acid used in the com. manuf. of the pigment is that of agglomerating agent with resultant decrease of the sp. surface. Silica gel, and the alkaline salts with adsorption tendencies, such as Na₂CO₃, Na₂B₄O₇, n-sulfates, etc., have a similar effect. Heating 2 to 3 parts by wt. of a muddy gray-violet Cr oxide hydrate contg. 50% H₂O for 8 to 10 hrs. at 260-280° in an autoclave in the presence of one part of any of these agglomerating agents in 3 parts of H₂O, transforms it into the brilliant green pigment. The transformation action, therefore, occurs in concd. aq. solns as well as in fused H₃BO₃ solns. as in com. manuf. The addn. of Guignet's green to pptd. Cr oxide hydrate similarly favors transformation of the latter into the brilliant green. In accord with the discovery that an increase in the particle size is the cause of the color change, and that the H₂O is present as an adsorption compd., is the fact that with improvement of the brilliancy of the color the H₂O content is reduced continuously, as is the case with true adsorption compds., that the vapor pressure, however, is increased continuously as a necessary consequence of the reduced sp. surface. Vapor pressures were measured in a Hg-differential tensimeter against P₂O₅ at 20° to 80° and are plotted for a no. of greens of various brilliancies. The measurements are in accord with the vapor tension measurements found by other observers on other gels on aging and agglomeration (Zsigmondy, *Kolloid-chemie*, 3rd ed., p. 231(1920); cf. *C. A.* 15, 462). The reduced reactivity of the brilliant colored greens is further evidence of the decreased sp. surface. The amorphous character of the pptd. Cr oxide hydrate is not altered during the transformation into Guignet green. F. A. WERTZ

Chinese wood oil. I. W. NAGEL AND J. GRÜSS. *Z. angew. Chem.* 39, 10-3(1926).—The various theories advanced in explanation of the gel formation of tung oil on heating are reviewed. To study the gelatinization process, the Me esters were used instead of the glycerides. The β -eleostearic Me ester is easily produced by allowing 3% HCl in MeOH to react for 24 hrs. on α -eleostearic acid; transformation into the β -form occurs. α -Eleostearic Me ester is produced in almost theoretical yield from α -eleostearic acid and diazomethane in Et₂O; or more simply by the action of MeOH-KOH soln. on tung oil or its Et₂O soln. Contrary to expectation, this reaction, instead of causing sapon., converted the glyceryl ester into the Me ester. In the heating expts. on the Me esters at 240° in an atm. of CO₂, the progress of the polymerization was studied by detn. of I nos. Gel formation does not occur with the Me esters, but the I no. invariably falls to a min. of 80 to 90; this indicates the formation of a dimol polymer. The various possible formulas for such a polymer are given. On heating wood oil itself, the I no. of the oil, just prior to gelatinization, is 110 to 120. Wolff

(*C. A.* 7, 2125) has found that about 40% of a tung oil gel consists of unchanged oil, and 60% of polymerization product. The 1 no. found agrees fairly well with the calcd. 1 no. for 60% of dimol. polymerization product. To avoid the uncertainty of obtaining a sample of the oil just prior to gel formation, gelatinized oil was dissolved in 10% HCl in Et₂O, either in the cold or by boiling; after evapn. the residue showed the same 1 no. of 100 to 120 as the oil just before gelling and could again be gelatinized by repeated heating. All the possible formulas for the dipolymers are characterized by the formation of tetramethylene ring and attempts to identify this structure in the polymerized oils are being made. In expts. with esters of higher alcs., the tendency to gel formation increased with the mol. wt.; the glycol ester gels completely although it yields 36% distillate, as against 0 distillate for the glyceryl ester. Wood oil can be gelatinized by the action of 10% HCl in Et₂O by careful regulation of the conditions, usually in 7 hrs. in the cold. The same HCl-Et₂O soln. dissolves wood oil gel, so that the reaction is reversible similar to that found by Harries and Nagel with shellac (*C. A.* 18, 1057). The gel formation appears to be due to the tendency of the heavy dipolymer to form aggregates.

Sb sulfides (CURRIE) 6. Rapid oxidation of drying oils and "anti-oxygens" (TARADOIRE) 27.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The determination of the higher fatty acids insoluble in water. I. S. H. BERTRAM. *Z. deut. Oel-Fett-Ind.* 45, 733-6 (1925).—The following is a quant. method for detg. the higher fatty acids (palmitic acid and its homologs) in a fat or in a mixt. of fatty acids, based upon the splitting of the double C bond by oxidation with alk. KMnO₄ soln. Weigh 5 g. of the sample into a 300-cc. Erlenmeyer flask and boil under reflux for 1 hr. with 75 cc. 0.5 N alc. KOH; cool and titrate back with 0.5 N HCl. The difference between this result and that of a "blank" detn. without the fat gives the sapon. no. Transfer the soln. into a separatory funnel with 20 cc. alc. KOH and 75 cc. H₂O and shake out 3 times with petr. ether; wash the total petr.-ether ext. with dil. KOH, adding the wash water to the soap soln. Evap. the petr.-ether soln. to const. wt. and multiply by 20; this gives the % of unsapon. matter. Evap. all alc. from the soap soln. and dil. to about 200 cc.; cool, add 5 cc. of 50° Bé. KOH and a soln. of 30 g. KMnO₄ in 650 cc. H₂O, keeping the temp. below 25°; if the soln. does not remain violet-red, add more KMnO₄ soln. Shake well and allow to stand overnight. Decolorize with dil. H₂SO₄ and concd. NaHSO₃. Warm gently without boiling, until all MnO₂ has dissolved and the fatty acids form a clear layer. Shake out with petr. ether (b. 40-60°); wash the ext. 3 times with H₂O and evap. the petr.-ether soln.; the residue contains the satd. higher fatty acids and some volatile acids. Dissolve the residue, with 200 cc. H₂O, some NH₄OH and 30 cc. of 10% NH₄Cl soln. and ppt. hot with an excess of MgSO₄ soln.; boil, cool, filter on a folded filter and wash. Treat the filter with its ppt. in an Erlenmeyer flask with dil. H₂SO₄, re-ppt. with NH₄OH, NH₄Cl and MgSO₄ and filter

as before. Boil the filter paper plus ppt. with dil. H_2SO_4 , cool and shake out with petr. ether; wash the ext. with H_2O , evap. to const. wt. and the residue then represents the higher fatty acids insol. in H_2O . Check analyses with known amts. of added acids show the method to be accurate within a few tenths %. An extended bibliography with crit. comments accompanies the article. P. ESCHER

Distillation of fatty acids. O. HAUSAMANN. *Chem.-Ztg.* 50, 41-2(1926).—This is a discussion of the process with some remarks on air-cooling in place of water-cooling for condensing. Air-cooling permits fractionation of the distillate and sepn. of the colored and odorous portion by reason of the fact that the horizontal cooling coils can be tapped at different places. E. SCHERUBEL

Can neutral fat be distilled with steam? C. STIEPEL. *Z. deut. Oel-Fett-Ind.* 45, 765-6(1925).—Lab. expts. with steam distn. at 250° , on low-grade fats under factory conditions, re-established the fact that neutral fats distil with steam only in minute amts., requiring 1000 parts or more by wt. of steam for each part of fat. P. ESCHER

The world production of vegetable oils. HJALMER HEIMBÜRGER. *Tekn. Tids.* 56 (Kem. afd.), 1-6(1926).—A statistical survey. A. R. ROSE

Stabilizing agents for oils. E. DE'CONNO, E. GOFFREDI AND C. DRAGONI. *Ann. chim. applicata* 15, 475-84(1925).—Since atm. O plays the chief role in the drying and onset of rancidity of oils and since it has been shown by Moureu (*C. A.* 14, 1303; 16, 1439; 17, 564) that certain compds. such as phenols retard the oxidation of acrolein, expts. were carried out to det. whether these same antioxidants were equally effective in stabilizing vegetable oils. (Cf. Moureu and Dufraisse, *C. A.* 16, 3737.) To this end linseed oil and olive oil, both in the pure state and after addn. of a stabilizing agent, were oxidized by passing O through each for 24 hrs. at room temp. Changes in the properties were detd. by comparing the sapon. no., the acetyl no., the relative and abs. I nos. and the Hehner index before and after treatment with O. Judged by these criteria phenol, hydroquinol, resorcinol or pyrogallol increased the rate of oxidation of both types of oils. Since these compds. inhibit the oxidation of acrolein, they resemble in this diverse action the action of I (cf. Moureu and Dufraisse, *C. A.* 17, 1951, 18, 2635). Under the same conditions, however, benzoic and salicylic acids had a powerful stabilizing action, the former being the more effective with olive oil and the latter with linseed oil. This would indicate that the inhibitory action is due to the CO_2H group, the simultaneous presence of the OH group in turn fortifying this action with drying oils and weakening it with non-drying oils. To det. whether the anti-oxidant action was due to the CO_2H group itself or to the combined action of CO_2H and the C_6H_5 nucleus, the effect of HOAc and glycolic acid under similar conditions was detd. Both these retarded oxidation in the same manner as benzoic or salicylic acid, the presence of the OH group again favoring the stabilization of drying oils and the stabilization of non-drying oils. The most effective agent for linseed oil was glycolic acid, that for olive oil was HOAc, practically complete stabilization being effected with 0.1% and 0.5%, resp., under the conditions described. C. C. DAVIS

Rapid oxidation of drying oils and "anti-oxygens." F. TARADOIRE. *Compt. rend.* 182, 61-3(1926).—The retarding or inhibitory action of a large no. of anti-oxygen (Moureu and Dufraisse, *C. A.* 16, 1439) on the spontaneous combustion of cotton soaked with mixts. of drying oil, spirits of turpentine and drier was investigated. PhOH , β -naphthol and hydroquinone retard combustion. Guaiacol, α -naphthol, PhNH_2 , PhNMe_2 , Ph_2NH , quinuclidine and hexamethylenetetramine prevent it completely. Introduction of nitro groups in phenols and amines decreases the anti-oxidizing power, the activity decreasing with increase in the no. of groups introduced. With 2 g. S per 100 g. of soaked cotton, the temp. rose to 100° and then fell slowly, showing that S is inactive at ordinary temp. but becomes active at about 100° . A. P. C.

A survey of equipment used in modern soap manufacture. C. RICHTER. *Industria saponiera* 26, 1-3(1926); cf. *C. A.* 20, 673.—In conclusion presses and machinery for prepg. soap powders are described and illustrated. C. C. DAVIS

Determination of the turbidity point of soap solutions. H. SEYFERTH. *Z. deut. Oel-Fett-Ind.* 45, 766-7(1925).—Referring to Braun's article on the detn. of the turbidity point (*C. A.* 20, 673), S. suggests the use of 0.60% soap solns. (=0.36% fatty acids) in place of 3% solns. which are much too concd. for actual practice, and also recommends Herbig's simple app. for the detn., adding a side illumination to produce a Tyndall-cone effect in place of the closed mantle with opposite slits. P. ESCHER

The aging of liquid soap. C. W. CROWELL. *Soap* 1, 22(1926).—Liquid soap must be aged at least 1 month in order to obtain permanent clarification. To det. the

anhyd. soap content of liquid soaps make a standard hard H_2O by dissolving 1.787 g. $CaCO_3$ in HCl , evap., neutralize with NH_4OH and make up to 1 l. Into a 200-cc. oil bottle $1\frac{3}{4}$ in. in diam. and $6\frac{1}{4}$ in. high put 100 cc. of the standard hard H_2O from a calibrated pipet, add the unknown liquid soap dropwise, shaking after each addition until a permanent lather lasting 3 min. is formed when the bottle is resting on its side. The no. of cc. of unknown soap necessary to produce this permanent lather may be read directly as the % of anhyd. soap or % soap value. The total solids of the unknown soap may be obtained by multiplying the soap value by the factor 1.33. E. S.

Adsorption as a preliminary phase of alkaline saponification. E. L. LEDERER. *Z. deut. Oel-Fett-Ind.* 45, 749-51(1925).—From preliminary expts. L. concludes that the ionic combination of the alkali base with the fatty acids of the glycerides is preceded by an adsorption phenomenon that follows Freundlich's adsorption law, $y/m = c.x^n$, where y is the adsorbed part, x the unadsorbed part, m the amt. of the adsorbent, while c and n are consts., c of varying value and n of a value between 0.1 and 0.8. L. mixed 15 g. acid-free tallow with varying amts. of 3 N $NaOH$ at a temp. slightly above the m. p. of tallow, stirring until cold and keeping the vol. at 50 cc. L. then attempted to det. the free and combined alkali by direct titration and also by salting out the combined soap with $NaCl$. In both attempts addition of the electrolytes disturbed the degree of hydrolysis and the attempt to establish a definite relation between electrolyte content and degree of hydrolysis failed for want of a sufficient no. of observations. Similar detns. were made with 5 g. tallow and N $NaOH$ soln at 100° . Expts. with the ultramicroscope, which should show an optically empty field with CCl_4 as a solvent for castor oil and alc. for $NaOH$ (0.005 N in both cases), failed through the inability to introduce the solns. after the visual adjustment has been made. P. ESCHER

Sunflower (PIERAERTS) 11D.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

A review of sugar technology in 1925. ANON. *Facts about Sugar* 21, 184-6 (1926).—The review consists of the studies in beet culture, the beet spacing test, sugar cane agriculture, progress in chem. research, deterioration of sugar in storage, mech. problems, pressure evapn., improved defecation, changes in boiling system, the handling of mill juices and general tendencies. T. MARKOVITS

The sugar campaign of 1925 in Java. S. N. QUAR. *Facts about Sugar* 21, 82 (1926).—Some results attained in a season of record production and the importance of new cane varieties are given. T. MARKOVITS

Seed selection of sugar cane. A. H. ROSENFELD. *Facts about Sugar* 20, 1242-3 (1925).—An account of some demonstration expts. conducted at Tucuman and their results. T. MARKOVITS

Preservation of sugar-beet-pulps by means of lactic enzyme. L. D. GEMBLoux and No. 21 (1925); *Bull. assoc. inst. sup. fermentations Gand* 27, *Ann. soc. brasseurs* 35, 70(1926).—By addn. to the pulp, as it was being put in the silo, of lactic enzymes produced in the maturing of cream, the loss of solids was reduced from 33 to 24% and the pulp retained a fresh odor and flavor and underwent no butyric fermentation. A. PAPINEAU-COUTURE

Weighing raw sugar juices. W. F. ALEWYN. *De Suikerindustrie, Java; Facts about Sugar* 20, 1190-4(1925).—App. invented in Java for which exceptional accuracy is claimed. The operation of the app. is entirely automatic. T. MARKOVITS

Boiling methods and filterability. W. E. SMITH. *Facts about Sugar* 21, 134-6 (1926).—Relation of boiling practice to filtration qualities of raw sugars as shown by laboratory investigations. T. MARKOVITS

Development of the saccharimeter. F. T. DILLINGHAM. *Facts about Sugar* 20, 1210 3(1925).—A brief sketch of the history of the saccharimeter. T. MARKOVITS

Determination of the velocity of crystallization of saccharose. I. A. KUCHARENKO. *Sucre belge* 45, 3-8(1925).—The method of detg. the velocity of crystn. of saccharose in supersatd. soln. is described. The soln. for the test is drawn from the hot sirup filter into a bottle, the operation being so conducted as to avoid the entrance of dust

particles. The supersatd. soln. is further protected from contact with external crystals by being covered with a layer of pure water. Portions of this soln. are then placed in the thermostat and brought to the desired temp. A no. of seed crystals are measured and weighed and brought to the same temp. as the soln. which is then poured on the crystals. At the expiration of a definite time the crystals are removed, dried and weighed. The velocity of crystn. is then calcd. according to the formula given in the paper.

T. MARKOVITS

A method of preparing perfect sugar crystals. I. A. KUCHARENKO. *Sucre belge* 44, 112-3(1925).—In expts. on the velocity of crystn. of saccharose it is necessary to have perfect crystals for introducing into the test soln. K. gives a method of prepg these crystals by seeding selected crystals into a pure sugar soln. having a satn. coeff between 1.005 and 1.010 at lab. temp. The crystals are kept in the soln. in a thermostat until they are about 0.5 g. in weight. The crystals are examd. and those which do not show regular development are discarded. The process of selection is repeated several times until perfect crystals of the desired size are left.

T. MARKOVITS

Influence of mineral salts on the crystallization of sugar. A. F. KAUZNETZOV. *Zapiski; Sucre belge* 45, 9(1925).—A method of studying the effect of salts on the crystn. of saccharose is described. The carbonates of K and Na retard crystn., but their effect decreases with decreasing temp. The Ca salts of aspartic and nitric acids also retard crystn. Their melassigenic influence increases with decreasing temp. CaCl_2 accelerates crystn. Recent physico-chem. theories of crystn. are employed in this paper.

T. MARKOVITS

The composition of non-sugars. H. F. BOMOMTI AND W. R. MCALLEP. *Facts about Sugar* 21, 39-41(1926).—A study of the influence of boiling methods upon the compn. of non-sugars from a refining standpoint. The work indicated the compn. of non-sugar in com. sugar is influenced by the boiling method. By modifying boiling methods toward straight boiling the non-sugar can be improved with respect to ash, sulfates, non-settling matter and color, but the glucose % of non-sugar will be reduced. The washing required to bring low-polarizing sugar up to the required polarization adversely affects the compn. of the non-sugar from a refining standpoint.

T. M.

Hawaii's experience in the use of fertilizer (VERRET) 15.

29—LEATHER AND GLUE

ALLEN ROGERS

Behavior of deaminized collagen. Further evidence in favor of the chemical nature of tanning. A. W. THOMAS AND S. B. FOSTER. *J. Am. Chem. Soc.* 48, 489-501(1926).—Treatment of animal skin with HNO_2 yields a product of diminished N content. The isoelec. point of such "deaminized collagen" is in the region of p_H 3.5 to 4 as revealed by the dye technic, swelling and point of min. rate of tannage. "Deaminized" calf skin shows 2 points of min. plumping, p_H 4.0 and 8.3. It swells in solns. of p_H 6 to 10 to a remarkable extent in comparison with raw skin. From a purely chem. point of view, the more acid character of "deaminized collagen" in comparison with collagen is to be expected upon removal of N groups. If the combination between skin and org. tannins is fundamentally a chem. reaction between the N groups of the protein mol. and the acidic tannins, then collagen which has been impoverished in its N groups should show a diminished rate of tanning in acid solns. and a shift in the min. rate to a more acid region. This has been found to be true.

C. J. WEST

Aminohydroxysulfonic acids in the dyeing of hides. VITTORIO CASABURI. *Boll. uff. r. staz. sper. ind. pelli* 3, 61-9(1925).—"Epidermol C" of Cassella which lately has appeared on the market is recommended for different purposes and especially as a base in dyeing Cr-tanned hides and as a mordant in dyeing glove leather. It contains tanning material, apparently of the pyrocatechol group, $\text{Cr}(\text{OAc})_3$ and bisulfate. The combination of tanning and mordanting does not give results as good as a mordant alone. Of various compds. examd. H-acid was found to be the most suitable as it combines easily with Cr, Al, Fe, Cu, Mn, etc., yielding mordants. Their application is given in details.

M. LUTHY

Activities of pancreatic enzymes used in bating upon different substrates. J. A. WILSON AND H. B. MERRILL. *J. Am. Leather Chem. Assoc.* 21, 50-3(1926).—Detns.

of the hydrolytic powers of 9 com. pancreatins upon casein, collagen, elastin, keratose and olive oil show that the individual enzymes making up the com. material may be present in very variable proportions. In measuring the activity of pancreatin upon some particular material, that material itself and not some substitute must be used as substrate. In detg. the value of a pancreatin for bating, it is necessary to measure its activity separately upon each important constituent of the skin to be bated.

J. A. WILSON

Films of adhesives. J. W. MCBAIN AND D. G. HOPKINS. *J. Phys. Chem.* **30**, 114-25 (1926).—Detns. were made of the tensile strengths of thin films of high-grade glue and gelatin, purified gelatin, isinglass, and glue size. The first 2 adhesives gave values of approx. 5.5 tons per in. or twice that with glue size. Both refined isinglass and glue size have a tenacity of approx. 9500 lbs./sq. in. 10-15% of PbSO_4 , ZnO , aloxite or flint does not affect the tensile strength of the film appreciably but 66 $\frac{2}{3}$ % lowers it a great deal. $\text{K}_2\text{Cr}_2\text{O}_7$ increases the strength of the film while formalin has no effect. K alum, Na benzoate, Na formate, Na salicylate and glucose reduce the tensile strength. Films prepd. from 25% solns. of glue in H_2O or in 0.1 N HCl were equally tenacious, whereas those from glue dissolved in 5.1 N NaOH were much weaker. Heating such aq. alk., or acid solns. of glue continuously for 28 days at 55-58° causes a relatively slight loss in tensile strength, but higher temps. cause the films to become brittle.

HARRY B. WEISER

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Changes in the state of dispersion of rubber. F. EVERS. *Kautschuk Nov.*, 1925, 8; *Gummi-Ztg.* **40**, 887-8.—Since neither the hydrogenation nor the decompn. of rubber has so far yielded any definite information concerning the structure of the rubber mol., the latter problem was attacked by utilizing the *catalytic action of AlCl_3* . Plasticized rubber was boiled in PhCl or xylene with AlCl_3 . After the violent reaction had ended, the AlCl_3 was removed and the reaction products were pptd. with EtOH . The ppt. (6.4 g. from 10 g. rubber) resembled the rubber hydrochloride obtained in $(\text{CH}_2\text{Cl})_2$ and contained in %: C 80.86, H 10.03, Cl 3.13, though the analysis is only approx. This *disaggregated product* differed from the plasticized rubber in that it dissolved in C_6H_6 with swelling and in that it reacted violently with Br with evolution of HBr. *Its viscosity curves* were of similar character, though far apart. Thus 1% of plasticized rubber in C_6H_6 had a viscosity of 1.45 and 1.08 at 20° and 43°, resp., whereas after boiling in PhCl with AlCl_3 the values were 0.42 and 0.28.

C. C. DAVIS

The oxidizing capacity of a one-phase rubber gel compared with raw rubber. H. FEUCHTER. *Kautschuk Aug.*, 1925, 11; *Gummi-Ztg.* **40**, 888.—When thin films of "diffused rubber" (cf. *C. A.* **19**, 2576) and of smoked sheet were exposed to sunlight, the former oxidized much more slowly than smoked sheet, but nevertheless lost its elasticity faster. This seeming paradox is probably due to the action of the non-rubber colloids in raw rubber, which are themselves oxidized and thus protect the rubber phase. The results indicate in general that oxidation is not *per se* a criterion of aging, for only when the rubber phase itself has succumbed to oxidation does a rapid decrease in the elasticity occur.

C. C. DAVIS

The process of mastication. A discussion of theories of structure. E. A. HAUSER AND H. DANNENBERG. *Kautschuk Nov.*, 1925; *Gummi-Ztg.* **40**, 1043.—The two-phase theory of the structure of rubber in conjunction with the recently discovered structure of latex particles (cf. Hauser, *C. A.* **19**, 1962, 2280; **20**, 677) is adequate to explain the phenomena accompanying mastication and dispersion in solvents. See also Bary, *C. A.* **20**, 677.

C. C. DAVIS

New ebonite testing accessories for the Schopper machine. R. HOUWINK. *India Rubber J.* **71**, 227-8 (1926).

C. C. DAVIS

The problem of vulcanization. IV. Shell aggregation and the colloidal crystallization of rubber. H. FEUCHTER. *Kolloidchem. Beihfte* **21**, 171-94 (1925).—In extending and elaborating his earlier theory (*C. A.* **18**, 1765; **19**, 1207, 2576), F. develops the concept of rubber as a single-phase gel composed of an aggregation of chemically identical particles. These particles are spheroidal and are built up of a series of concentric shells of "polyprene" mols. or nuclei, such a structure involving colloidal polymerization. The spheroids or rubber *molecules* can exist as sep. individual units, in which case they are the latex particle, or they may be held together by chem. valency forces.

In the latter case the double binding system between the polyprene nuclei on the surface of the concentric spheres on the one hand, and between the surfaces of the adjacent spheres on the other, leads to a network which may be regarded as a gel skeleton of the single-phase gel. Under these conditions a phase crystn. exists, in which the network or gel skeleton is in an unstable state, for the disruptive forces are not great enough to allow of complete crystn. The concepts are in general hypothetical and are not supported by exptl. evidence. Furthermore no reference is made to the application of the theory to mastication, vulcanization or swelling, though the phenomena of elasticity, "grain" and crystn. are explained.

C. C. DAVIS

CHEMICAL ABSTRACTS

Vol. 20.

APRIL 20, 1926

No. 8

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

The ultrabalance. R. WAAG. *Umschau* 30, 115-7(1926).—A balance, sensitive to 1 part in 300,000,000 ($\frac{1}{10,000,000}$ g. for a 30 g. load) is described. Weighing to $\frac{1}{100,000}$ g. is made in the usual way, the pointer swing being observed with a lens. The $\frac{1}{1,000,000}$ g. readings are detd. and the $\frac{1}{10,000,000}$ readings are estd. by observing from a distance the movement of a spot of light reflected by a mirror on the balance beam.

R. L. DODGE

A new sorption balance. J. W. MCBAIN AND A. M. BAKR. *J. Am. Chem. Soc.* 48, 690-5(1926).—A flat, helical spring of silica is made by heating a SiO_2 rod and drawing it out quickly, then wrapping the resulting fiber about a C rod of suitable diam., heating the fiber at the point where it is being bent. The elongation of the spring under varying known wts. and at several temps. over the range in which it is to be used is detd. Elongations are read by means of a traveling microscope. The spring, from the end of which is suspended a bucket contg. the adsorbent, is supported within a glass tube contg. a thin-walled glass bulb holding the liquid whose vapor is to be adsorbed. After evacuating the system and sealing off the tube, the glass bulb is broken by a magnetic device. The downward movement of the spring measures the amt. of vapor adsorbed. Investigations of sorption above and below the crit. points can be made readily.

F. L. BROWNE

Fractionating column calculations. T. S. CARSWELL. *Ind. Eng. Chem.* 18, 294-5(1926).—The relationship between the height of the equiv. theoretical plate in cm (H. E. T. P.) and the radius in cm. (r) of packing rings with the diam. and height equal is $H. E. T. P. = 47 r$. The relationship between the H. E. T. P. and the substance distd. for a definite column and type of packing is $H. E. T. P. = k Md/T$, where M = mol. wt. of substance, d = d. of backflow, T = abs. b. p. of substance, and k = const.

W. L. MCCABE

A mobile refrigerating unit. H. F. PIERCE. *Ind. Eng. Chem.* 18, 270-1(1926).—The unit consists of a motor-driven compressor pump, a cooling coil, an expansion valve, and an expansion coil located in a brine tank and mounted on a small truck. A 35% alcohol-water mixt. replaces the usual brine soln. and works at temps. as low as -15° ; it possesses a refrigerating capacity nearly equal to that of a 25% CaCl_2 soln. A max. temp. deviation of $\pm 0.25^\circ$ over a 2-week period is recorded.

W. H. BOYNTON

Rotary positive-pressure pumps for transportation of liquids and gases. R. DE TEMPLE. *Tech. Ind. Schweiz. Chem.-Ztg.* 1926, 1-6.—Descriptive.

W. L. B.

Plants for removing mist. HACK. *Chem.-Ztg.* 49, 1054-6(1925).—An elementary presentation of the causes of mist (clouds) in factories, etc., and the means for removing it by proper ventilation and the use of preheated air. Illustrative calcs. are given.

W. C. EBAUGH

The Ljungström air preheater. WILHELM GUMZ. *Feuerungstechnik* 13, 217-20, 248, 9(1925).—The preheater (cf. Brolinson, C. A. 18, 2620) is described and discussed, and a series of boiler test results is presented.

ERNEST W. THIELE

An ebullition device for low temperature and vacuum distillation. A. F. O. GERMANN AND D. M. BROSEL. *J. Phys. Chem.* 29, 1528-32(1925).—A device is described for adapting the ordinary ebullition tube to obtain effervescent distn. without the use of any foreign gas and hence particularly useful in the purification of gases or in vacuum distn. Expts. on the purification of technical COCl_2 and mixts. of COCl_2 and SO_2 using the new app. and the simple distg. tube showed the superiority of the former. The phenomenon of ebullition is discussed.

R. E. GIBSON

Turbidimeter for accurate measurements of low turbidities. J. R. BAYLIS. *Ind. Eng. Chem.* 18, 311-2(1926).—A simple app. is described in detail for comparing the turbidity of liquids with samples of known turbidity. The turbidity values for the known standards are detd. with a Jackson candle turbidimeter. The comparison

method described readily detects a turbidity of 0.1 part per million, but is accurate only for turbidities less than 2. The turbidities are compared in glass tubes so arranged that a perfectly blue light is underneath the tubes, while white light shines through the tubes. Any matter in suspension reflects white light rays and cuts out some of the blue light.

R. L. DODGE

Enclosed continuous filter. J. F. WAIT. *Ind. Eng. Chem.* 18, 295-7(1926). A description of an app. for continuous filtration applicable to volatile fluids at elevated temps. A pressure differential up to 14 atm. is employed which does not expose the material to air.

W. L. MCCABE

A modified fusion pot. V. S. BABASINIAN AND R. D. BILLINGER. *Ind. Eng. Chem.* 18, 340(1926).—The Ni pot described was designed for alk. fusions of org. compds used in the lab. prepn. of dyes. It can be used as an autoclave for high-pressure work.

E. J. C

Combined distillation and return cooler. L. E. LÖFBERG. *Chem.-Ztg.* 50, 86(1926); 1 cut.—The app. consists of 2 superimposed sections. If H_2O is used in the lower section it acts as a return cooler; if in the upper section, it acts as a distn. cooler.

J. H. MOORE

Report on a leak in a chlorine container at the Zinnwerke Wilhelmsburg G. m. b. H. FR. BÖRNER. *Chem.-Ztg.* 50, 85-6(1926).

J. H. MOORE

New stopper for a Kjeldahl flask, with rustless steel wire holder. RUDOLF WEBER. *Chem.-Ztg.* 50, 86(1926); 1 cut.

J. H. MOORE

Apparatus for determining the apparent specific gravity and the porosity of substances. HEINRICH HERBST. *Chem.-Ztg.* 50, 49(1926); 1 cut.—The method is based on the displacement of Hg by the substance.

J. H. MOORE

A new electrical recorder. T. R. HARRISON. *J. Optical Soc. Am.* 12, 165-72(1926).—Description of recording millivoltmeter of the d'Arsonval galvanometer type for use with thermocouples, radiation pyrometers, resistance thermometers, thermal cond. gas analysis app., etc. The instrument embodies many new features contributing to ruggedness, convenience of operation and accuracy. The manufacturers are the Brown Instrument Co., Philadelphia, Pa.

R. L. DODGE

Apparatus for electrical heating and evaporating. ANON. *Chem.-Ztg.* 50, 49(1926); 1 cut.—C filament lamps form the heating element.

J. H. MOORE

An electrode vessel jacketed for work at various temperatures. S. O. RAWLINGS. *Chemistry & Industry* 45, 73(1926).—The customary electrode of H, Ag, etc., is immersed in the usual way in the liquid to be examd. The liquid container is a double-walled glass vessel. The space between the walls is kept full of running H_2O from a thermostat maintained at the working temp. The inner vessel is connected by a three-way cock either to a waste tube or to the remainder of the app., consisting of a salt bridge of satd NH_4NO_3 soln. and a calomel electrode.

R. L. DODGE

Lunettes-Lumina, a new laboratory instrument. HERMAN WEISZ. *Ann. chim. anal. chim. appl.* 7, 326(1925).—An Austrian firm has placed on the market a kind of blue glass spectacles which permit one to distinguish between colors under artificial illumination as in daylight.

W. T. H

Microscope and ultra-violet light (LUCAS) 9. Use and revivification of decolorizing C (BLOCK) 18.

Apparatus and heat-exchange system for liquefying and separating constituents of air or other gaseous mixtures. R. F. MEWES AND R. K. E. MEWES. *Brit.* 236,608, Feb. 4, 1924.

Apparatus for evaporating brine, etc. R. FRANCE. *Brit.* 242,018, Aug. 23, 1924. The app. comprises an open pan and a tubular heater through which the soln. undergoing evapn. is circulated by a pump.

Apparatus for filtering water, wine, beer, oils or other liquids. J. M. HINCHLEY AND STREAM-LINE FILTER CO., LTD. *Brit.* 236,608, March 4, 1924.

Filter bed for water or other liquids. F. B. LEOPOLD. *U. S.* 1,572,398, Feb. 9. Structural features.

Apparatus for destructive distillation of material in contact with a bath of molten metal. A. M. DUCKHAM. *U. S.* 1,572,779, Feb. 9. A chain carrying transverse plates moves through the distg. chamber and serves to depress the material undergoing distn. into intimate contact with a bath of molten metal.

Apparatus for making extracts, emulsions, suspensions, etc. N. BENDIXEN, W. E. McKECHNIE AND E. L. RRID. *Brit.* 242,020, Aug. 27, 1924. A corrugated or serrated

grid is arranged in a liquid container around a screw propeller or similar device which forces material outwards against the grid.

Storing gases in absorbent material. GAS ACCUMULATOR CO. (United Kingdom), LTD. Brit. 242,241, Nov. 1, 1924. Vessels for storing C_2H_2 and the like are filled with cellulose, sawdust, kapok or similar material which is rendered capable of resisting local explosions without charring by treatment with $CaCl_2$ and Na silicate or with substances reacting to form Cu or Zn resinate or similar insol. compds.

Gas-fired shaft furnace for burning lime, cement, dolomite, etc. R. DE BAR-TOLOMEIS and SOC. ANON. FORN ED IMPIANTI INDUSTRIALI. Brit. 236,776, Oct. 8, 1924.

Rotary "continuous" furnace or kiln. A. H. PEHRSON. U. S. 1,572,805, Feb. 9.

Device for discharging a container into another below the first. AUGUST SOMMERMEYER. Norw. 42,208, Nov. 23, 1925. Mech. features.

Thermionic valves. S. R. MULLARD and MULLARD RADIO VALVE CO., LTD. Brit. 241,996, Aug. 1, 1924. A cathode is formed by making a fine tube of a mixt. of Th or other electron-emitting material with W, Mo or other metal of high m. p. and mounting the tube on a filament of W, Mo or similar refractory metal. The Th may be produced in the mixt. by reduction of thoria by H. A W wire is inserted in the tube and may be etched or partially dissolved by $NaNO_3$ to prevent overheating on the ends. The use of U also is mentioned.

Thermionic valves. GENERAL ELECTRIC CO., LTD. AND C. J. SMITHELLS. Brit. 241,984, July 28, 1924. A coating of electron-emitting material (preferably carbonates of alk. earth metals) is applied to a conductor by reducing the material, suspended in a liquid, to a fine state of subdivision by use of a colloid mill. The conductor is subsequently heated in a vacuum or inert gas to convert the carbonates to oxides. From 5 to 50 such coatings may be successively applied.

Thermionic valves. E. Y. ROBINSON. Brit. 236,615, March 26, 1924. A tubular or sheet metal cathode comprises a core such as W or Mo and a coating of Pt (or an alloy) or Ni upon which a covering of electron-emitting material is deposited. The Pt or Ni may be deposited electrolytically. Cf. C. A. 19, 911.

Thermoelectric element. O. HERMANN. U. S. 1,572,117, Feb. 9. An alloy of Ni 81, Mo 17 and V 2% is used for negative thermoelec. elements together with positive elements comprising Ni 40 and Cu 60%.

Thermostatic device for controlling fuel valves. O. SCHWIMMER. U. S. 1,572,969, Feb. 16.

Thermostat. T. S. BEACHAM. Brit. 236,716, June 17, 1924.

Thermostat for regulating steam valves, etc. J. M. KNEPPERS. Brit. 236,784, October 20, 1924.

Thermometer. M. FLEISCHER. Brit. 242,228, Nov. 3, 1924.

Photometer. H. LUX. U. S. 1,572,544, Feb. 9.

X-ray tube. C. C. VAN VOORHIS. U. S. 1,573,105, Feb. 16. Gas such as He is introduced into the tube by applying the gas to the surface of the tube and heating the latter to permit diffusion.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND BRIAN MEAD

Albert Richaud (1864–1925). "G. M." *J. pharm. chim.* [8], 2, 311–4 (1925).—An obituary. S. WALDBOTT

James Lewis Howe. S. C. LIND. *Ind. Eng. Chem.* 18, 434 (1926).—A brief biography, with portrait. E. J. C.

Aurel Babes. ST. MINOVICI. *Bull. soc. chim. România* 7, 63–4 (1925).—Obituary with a list of articles published by B. A. PAPINEAU-COUTURE

Meetings of the international nomenclature committees, Paris, October, 1925.

A. M. PATTERSON. *Ind. Eng. Chem.* 18, 320–1 (1926).—Tentative decisions for both inorg. and org. nomenclature are unofficially reported. E. J. C.

Radii of atoms and ions. W. P. DAVEY. *Chem. Rev.* 2, 349–67 (1925).—D. defines as the radius of the atoms and ions in crystals the half distance of the closest approach of the atoms, i. e., the "packing radius" of the individual fields of forces, which latter may or may not be spherical. Numerous values are given and are shown to be a periodic function of the no. of electrons in the outer shell. 11 references. G. C.

Separation of hafnium and zirconium by fractional precipitation of their phosphates from a solution containing oxalic acid. J. H. DE BOER. *Z. anorg. allgem. Chem.* 150,

210-6(1926).—Freshly pptd. and wet phosphates of Zr and Hf are sol. in oxalic, phosphoric and sulfuric acids, forming complex compds. which easily decompose. Thus heating or addn. of EtOH or a mineral acid to the soln. in oxalic acid or of water to that in H_3PO_4 or H_2SO_4 suffices to ppt. the phosphates. The content of Hf in this ppt. expressed by the fraction $\text{Hf}/(\text{Hf} + \text{Zr})$ is higher than in the original soln. The pptn. from concd. satd. oxalic acid with HCl gave the best results, permitting the prepn. of a 97% pure product after 26 fractional pptns., whereas several hundred fractional crysts. are necessary when the original method of Hevesy with the double fluorides is used (cf. *C. A.* 10, 1672). A vacuum X-ray spectrograph was applied for the detn. of Hf pyrophosphate in the individual fractions, the intensity of the La_1 -line having been compared with that of La_1 of tantalum pentoxide. The results were confirmed by chem. analysis. Metallic Hf obtained from the phosphate by a series of reactions have d. 12.1. F. K.

The possible enhanced activity of newly formed molecules. F. R. GOSS AND C. K. INGOLD. *J. Chem. Soc.* 127, 2776-81(1926).—In many org. reactions in which it seems obvious that an intermediate product is first formed which subsequently decomposes to give the final products, it is found that subjecting the pure intermediate product in question to the same exptl. conditions fails to bring about the formation of the final products expected. The suggestion is made that "intermediates may be produced in a reactive condition in which they are capable of changes which cannot occur after the energy assocd. with the formation of the compd. has been dissipated." F. L. B.

Isotropic ions and structure of the molecules and crystal lattices. F. HUND. *Physik. Z.* 26, 682-5(1925).—The shape of the mols. and of the crystal lattice in which a substance crystallizes can be explained in terms of isotropic ions; therefore one cannot infer the structure of the ion from the crystal structure and the shape of the mols. This does not imply, however, that isotropic properties are the only controlling factors. G. CALINGAERT

Dielectric constant and molecular structure. K. T. COMPTON. *Science* 63, 553-5 (1926).—An address. G. CALINGAERT

The crystalline structure of chrysoberyl. W. LAWRENCE BRAGG AND G. B. BROWN. *Proc. Roy. Soc. (London)* 110A, 34-63(1926).—Ionization spectrometer measurements and X-ray photographs taken with a revolving crystal have been used to examine the structure of chrysoberyl, BeAl_2O_4 . The unit cell, contg. 4 mols., is orthorhombic with a , b , c equal to 4.42, 9.39, 5.47 A. U., resp. The structure belongs to the space-group V_h^{16} . Because they scatter X-rays so feebly, the Be atoms could not be located. Oxygen atoms are arranged in hexagonal close-packing, slightly distorted by the presence of Al atoms in spaces between six O atoms. Relative intensities are used to det. the parameters governing the positions of Al and O atoms. The structure is somewhat analogous to that of spinel, MgAl_2O_4 , although in the latter crystal the O atoms are in cubic close-packing. R. J. HAVIGHURST

The crystal structure of the high-temperature (β -) modification of quartz. R. W. G. WYCKOFF. *Am. J. Sci.* 11, 101-12(1926).—Data from powder and spectrum X-ray photographs of quartz above its inversion point, and from Laue photographs show that each Si atom is surrounded by a tetrahedron of O atom and each O atom is equally distant from two Si atoms. There is no evidence for the existence of chem. mols. in the crystal. Cf. *C. A.* 20, 318. R. J. HAVIGHURST

A röntgenographic determination of the atomic arrangement in the mixed crystal series gold-copper and palladium-copper. C. H. JOHANSSON AND J. O. LINDE. *Ann. Physik* 78, 439-60(1925).—Certain Debye-Scherrer interference maxima which Bain found from an alloy of Cu-Au contg. 75 at. % Cu, and which he attributed to a regular arrangement of the solute atoms (Au) in the lattice of the solvent (Cu) in accordance with Tammann's theory of a "normal distribution" in the lattice of a solid soln., have been obtained by J. and L. but are attributed to a compd. Cu_3Au . The existence of this compd., as well as one Cu-Au, is shown by elec. cond. measurements of Kurnakov, Zhemchuhni, and Zasedatlev. The authors have obtained extra lines from the alloy contg. 50% Cu, which correspond to a tetragonal face-centered lattice with axial ratio $a:c = 1.078$. These extra lines, as well as minima in the resistivity curves, were not obtained unless the alloys were cooled very slowly through the region of transition to the new compds. The solid soln. contg. 75% Au showed no trace of extra lines. In the system Pd-Cu, the face-centered cubic lattice goes over to a body-centered "CSC" lattice at 40 at. % Pd and reverts to the face-centered lattice at 50% Pd. Between 40 and 50% Pd, there was no trace of lines due to the face-centered lattice when a carefully annealed sample was used. Between these limits, the solid solns. show an abnormally large cond. R. J. HAVIGHURST

The crystal structure of argon; investigation of the structures of nitrogen and oxygen at liquid-hydrogen temperature. J. DE SMEDT and W. H. KEESOM. *Physica* 5, 344-6(1925); cf. *C. A.* 19, 1816.—The structure of solid A has been detd. and the results of Simon and von Simon fully confirmed (*C. A.* 18, 3128). Face-centered cubical structure was found, $d_{100} = 5.40$ A. U. ± 0.06 . The d at about 20° abs. is 1.68. Debye-Scherrer diagrams of solid O_2 and N_2 at 29° abs. showed as a preliminary result that the symmetry is probably lower than regular, tetragonal, hexagonal or trigonal. The work is being continued.

Crystal structure of germanium tetraiodide. F. M. JAEGER, P. TERPSTRA AND H. G. K. WESTENBRINK. *Verslag. Akad. Wetenschappen Amsterdam* 34, 721-40; *Proc. Acad. Sci. Amsterdam* 28, 747(1925).—The crystal structure of GeI_4 is detd. by Laue and spectral photographs, and some angles are measured directly. The unit cell is cubic and contains 8 mols., $d_{100} = 11.89$ A. U. The space group symmetry is T_h^6 , the same as in SnI_4 (Dickinson, *C. A.* 17, 1740), the crystal form is dyakisdo-decahedral.

Crystal angles, measured under the microscope. E. A. HILL. *J. Am. Chem. Soc.* 48, 651-4(1926).—A new method is described for the measurement, under the microscope, of solid crystal angles, and of the slope angles of crystal faces, by the use of the ordinary eye piece micrometer disks and the graduations of the fine adjustment screw.

The structure of molecules in relation to their optical anisotropy. II. Benzene and cyclohexane. K. R. RAMANATHAN. *Proc. Roy. Soc. (London)* 110A, 123-33(1926); cf. *C. A.* 19, 1973.—The method of the previous work is extended to the study of benzene and cyclohexane. Each atom is assumed to be isotropic. If the six C atoms in benzene are assumed to lie in a plane with their centers at the corners of a regular hexagon, the calcd. optical anisotropy comes out too high. If the C atoms are arranged on a puckered ring, with hydrogens joined to carbons at the tetrahedral angle, the calcd. and observed values of the optical anisotropy agree well, when the at. refractivity of C is assumed to be that of diamond, and the at. refractivity of H to be that in gaseous hydrogen. Calcd. and observed values of molar refractivity are also in good agreement. In the case of cyclohexane, the 6 extra H atoms are supposed to be attached to the C atoms alternately above and below the approx. plane of the C ring. The calcd. anisotropy agrees fairly well with the observed value. A simple glass app. is described for the measurement of the imperfection of polarization of the light scattered by vapors which require heating for their production.

The effect of three-dimensional (wechselseitige) compression on aluminum. G. SACHS and E. SCHIEBOLD. *Z. Ver. deut. Ing.* 69, 1557-61, 1601-4(1925).—By alternate hammering of Al cubes on the three perpendicular cube faces the metal was hardened, although the original cube form was maintained. The degree of hardening is not so great, for the same amt. of deformation, as in the case of hammering in one direction only. X ray examn. by the Debye-Scherrer method shows that, in the case of deformation by pressure in one direction only, the crystallites line up with (110) axes (cube face diagonals) parallel to the axis of deformation, but maintain a fortuitous orientation in other respects. In the case of three-dimensional compression the crystallites assume the positions made possible by a superposition of the three separate one-dimensional pressure effects. There are three equiv. positions of the Al single-crystal cubes, in each of which two pair of cube faces make angles of 45° with cube faces of the large test piece.

The relation between detecting power and crystal habit in galena and pyrite. P. GAUBERT. *Compt. rend.* 182, 143-6(1926).—Octahedral faces of galena are usually good detectors, while cube faces are poor ones. Especially pure crystals are poor detectors. In pyrite, the cube faces are better detectors than the octahedral faces. According to G.'s theory, detector action is produced by some impurity which has syncrystallized with the crystal, modifying its habit and forming thin layers parallel to the new faces.

Melting points of barium, strontium and calcium oxides. E. E. SCHUMACHER. *J. Am. Chem. Soc.* 48, 396-405(1926).—A new method for detg the m. ps. of certain oxides is described and illustrated. By this method BaO , SrO and CaO m. 2196° , 2703° K. and 2849° K., resp.

Recrystallization and loss of strength as shown by röntgenographs. G. SACHS AND E. SCHIEBOLD. *Z. Metallkunde* 17, 400-2(1925).—This is a study of the relation between crystal form and mech. strength of Al wire, drawn and heated to different temps. as revealed by Röntgen-ray photographs. Wire contg. 99.6% Al, drawn from 8.75

to 1.18 mm., was used and heated to various temps., mech. strength and röntgenographs being studied between 100° and 600°. Photographs are shown for room temp., 150, 200, 250, 300 and 550°. The strength drops sharply from 24.4 kg./sq. mm. at room temp. to 11.0 kg./sq. mm. at 250° and then rises slightly on account of the effect of impurities, being still as high as 11.7 at 550°. A curve is shown. From the röntgenographs it is seen that considerable loss in strength can take place with very little effect upon the crystal lattice, and no simple relation between strength and Röntgen-ray picture can be found. The röntgenographs, however, make possible the detn. of the lattice form and lattice const. of the material examd., the size of the individual reflecting spheres and their position with respect to the Röntgen rays. A diagram is shown from which the position of the various rings in the röntgenograph can be detd., using $\text{MoK}\alpha$ and $\text{K}\beta$.

H. STOERTZ

The potentials of thallium-antimony alloys. G. VINOGOROV AND G. PETRENKO. *Z. anorg. allgem. Chem.* 150, 258-60 (1926).—R. Williams made the assumption of the existence of a compd. SbTl_2 without being able to prep. it in a pure state (cf. *Z. anorg. allgem. Chem.* 50, 129 (1906)). The measurements of the potentials of the combination $\text{Tl-Sb alloy} | 1\text{N TiCl}_4 | \text{Tl}$, in which Tl-Sb alloys of various compns. were used, actually indicated the presence of this compd.

Remarks about the growth of crystals. P. TERPSTRA. *Verslag. Akad. Wetenschappen Amsterdam* 34, 776-8; *Proc. Acad. Sci. Amsterdam* 28, 794 (1925).—A discussion of the formulas derived by Valetton (*C. A.* 18, 1407, 3502).

G. CALINGAERT

Crystal form of some position isomers of dinitrotoluene. F. M. JÄGER. *Verslag Akad. Wetenschappen Amsterdam* 34, 848-52 (1925).—The crystal form is given for 5 of the 6 possible isomers. 2,3-: Rhombic bipyramidal, $a:b:c = 0.6352:1:0.3721$, cleavage along 0.001. 2,4-: Monoclinic prismatic, $a:b:c = 0.8553:1:0.5236$, $\beta = 84^\circ 37' 30''$, habitus prismatic along c . 2,6-: Rhombic bipyramidal (pseudo-hexagonal), $a:b:c = 0.5725:1:0.5324$, habitus extended along c . 3,4-: Monoclinic prismatic, $a:b:c = 0.8320:1:0.2465$, $\beta = 88^\circ 25'$, prismatic needles along c . 3,5-: Monoclinic prismatic (pseudorhombic), $a:b:c = 0.4691:1:0.5276$, $\beta = 89^\circ 51'$. From EtOAc the last crystallizes with 1 mol. of solvent as short monoclinic prisms, $a:b:c = 0.7143:1:0.3853$, $\beta = 73^\circ 58' 30''$. There is no analogy between these forms and those of mono- and trinitrotoluenes.

G. CALINGAERT

Physical properties of tungsten at high temperatures. C. ZWIKKER. *Physica* 5, 249-60, 319 (1925); cf. *C. A.* 19, 3056.—A new set of detns. is given, differing in some respects from those of Langmuir (*C. A.* 10, 1298) and of Worthing (*C. A.* 19, 2170). Light intensities and temps. were all detd. on a microphotometer bank by comparison with a standardized pyrometer lamp, of which the brightness (H)/current (i) curve is known. From H the apparent black temp. S was calcd. by means of Wien's equation. A second standardization without color filter allows measurements of surface brightness B . In order to convert black temp. S into true temp. T detns. were made of the emission coeff. e_λ { $\log_2 e_\lambda = c_2/2.303 \lambda [(1/T) - (1/S)]$ }. Two different types of W black-body radiators were constructed for this purpose (hollow W cylinders heated either by thermionic bombardment or by d. c.); the ratio of inside and outside brightness yields e_λ as a function of T . The color temp. T_c was found by measuring at different temps. the ratio of red to white radiation for black body and ordinary W. From these measurements the pseudoemissive power e_c ($e_c = e_\lambda E_{\lambda T} / E_{\lambda T_c}$) can also be evaluated. Values of B for black-body radiation in international candles/sq. cm. detd. in this manner (one I. C. equals 1.111 Hefner candles of 1922) are at $T = 1300^\circ$, $B = 0.015$; $T = 1500^\circ$, $B = 0.819$, $T = 2000^\circ$, $B = 50.1$, $T = 2600^\circ$, $B = 915$. From temp. and energy equil. in an "ideal" piece of W wire (no heat loss by conduction) the sp. resistance was calcd.; from the increase in resistance with time is calcd. the rate of evapn. as a temp. function. The latter was found to be in g. metal per sq. cm. per sec.: $\log_{10} m = 11.92 - (4.84 \times 10^{-4}/T) - 0.368 \log T - 0.00016 T$. From the $1/T$ coeff. follows for the heat of evapn. at zero abs. 221,000 cal./g. atom. The satd. vapor pressure of W in mm. Hg follows from $\log p = 12.02 - (4.84 \times 10^{-4}/T) + 0.132 \log T - 0.00016 T$; the metastable sublimation point is at 5220° abs. As to the temp. distribution on the W filament Z. finds that $\epsilon/T_m = A - 10^{-10}$ in which A is an arbitrary const., x measures the distance from some point on the wire, a is a const. $= 2.303 \sqrt{K_m T_m / 14 \eta_m}$, T_m is max. temp. of filament, k_m heat cond. and η_m total radiation/cm.² both for T_m . From pyrometric observations k_m and the Thomson effect σ were found. In a specially constructed tube

with 10^{-7} mm. vacuum the thermoelec. emission was detd.: $i = 60.2T^2e^{-52230/T}$ amps./cm. ($\phi = 4.50$ v.) for an anode potential zero. Part of the tabulated data follow: at 1500° abs. ($\lambda = 0.665\mu$) $\epsilon_\lambda = 0.451$; $S_\lambda = 1421^\circ$; $\epsilon_c = 0.387$; $T_c = 1517^\circ$; $B = 0.370$ I. C./cm.²; $\rho = 40.2 \mu$ Ohmcm.; total radiation $\eta = 5.52$ watts/cm.². At 2000° abs. in the same order: 0.440; 1859° ; 0.371; 2033° ; 23.2; 56.7 ; 24.0 . At 2500° : 0.427; 2275° ; 0.353; 2557° ; 279; 74.0 ; 69.4 . At 3000° abs.: 0.415; 2675° ; 0.337; 3094° ; 1490; 92.3 ; 162. At 3400° abs.: 0.407; 2978° ; 0.323; 3533° ; 4080; 107.8 ; 291. The cond. k varies from 1.22 watts/cm. per degree at 1800° abs. to 1.43 at 2800° abs.; the Thomson effect in μ V per degree from -18 at 1800° to -30 at 2400° .

B. J. C. VAN DER HOEVEN

The isomorphism of the molybdates of the rare earth metals with those of calcium, strontium, barium and lead. F. ZAMBONINI AND R. G. LEVI. *Atti accad. Lincei* [6], 2, 149-52, 225-30, 303-5, 377-83, 462-5(1925); cf. *Rivista ital. di min.* 54-5(1915); 18, 947; C. A. 19, 1529; Z. *Kryst.* 44, 80(1908).—Röntgenographic detns. made by the methods and app. previously used by L. using the Debye and Scherrer method show that CaMoO_4 , SrMoO_4 , BaMoO_4 and PbMoO_4 all have the same structure. The data are given in full. For the Ca, Sr and Ba compds. the value of a shows a gradual increase which is a linear function of the at. wts. of Ca, Sr and Ba. This fact was also observed by Vegard for the nitrates. The deviation from a linear function of the at. wt. is somewhat greater in ϵ_b . Z. and L. found the variation in the molybdates of Ca, Sr and Ba to be a linear function of the at. wts. within $\pm 1\%$. The data on the röntgenographic structures of the molybdates of La, Ce, Pr, Nd and Sm are given in the 4th paper, and in the last paper the deductions from these data are given. The isomorphism among these compds. is perfect. The spectrograms show identity in structure with only unimportant exceptions. The data show that in the isomorphous series of molybdates of the alk. earth metals and of those of the Ce group the elementary solids contain equiv. vols. of these compds. This fundamental question for the subject of isomorphism is decisively answered. In this series of molybdates the vol. of the elementary solid decreases regularly with increases in the at. wt. and in the at. no. (cf. Goldschmidt, *et al.*, C. A. 18, 316). Since these molybdates all possess the same structure this should also be revealed in their mixed crystals. Mixed crystals of CaMoO_4 with 6.5 to 29% $\text{Ce}_2(\text{MoO}_4)_3$ were examd. in detail by these methods but no particular structural characteristics were found. In the elementary solids CaMoO_4 and $\frac{1}{3}\text{Ce}_2(\text{MoO}_4)_3$ play an equal and replaceable role. In comparing the reticular constns. of the Ce earth molybdates with those of the alk. earths and Pb it is found that that of Sm is most like that of Ca while the values for the other rare earths fall between those for CaMoO_4 and SrMoO_4 . All 5 of the rare earth molybdates are completely miscible in PbMoO_4 while $\text{Sm}_2(\text{MoO}_4)_3$ gives mixed crystals in greater proportions with CaMoO_4 . E. J. W.

The determination of the melting point of graphitic carbon. EUGEN RISHKEVICH AND FRIEDRICH MERCK. Z. *Elektrochem.* 32, 42-7(1926); cf. C. A. 19, 1513, 2594.—The method used consisted in the measurement of the temp. of the interior of a hollow graphite rod. The graphite was Acheson graphite of 99.9% C and was elec. heated in an atm. of N-free argon. The av. value obtained for the m. p. was $3845^\circ \pm 45^\circ$, the av. deviation from the mean being about 20° .

Equal viscosities. O. FAUST. Z. *anorg. allgem. Chem.* 150, 175-6(1926).—Notes on a paper by Herz (cf. C. A. 19, 3392). There seems to be a connection between the mol. assocn. and the deviation from the regularity in the relationship of inner friction to the crit. temp.

EMIL KLARMANN

Vapor pressure of arsenic trioxide. E. R. RUSHTON AND FARRINGTON DANIELS. *J. Am. Chem. Soc.* 48, 384-9(1926).—Although octahedral As_2O_3 (m. 275°) is metastable above 100° , the rate of change to the stable monoclinic form (m. 315°) is so slow as to permit measurements of the vapor pressure of the former up to 250° or higher, depending on the rate of heating. The equation for the vapor-pressure curves are: octahedral $\log P = -(6670/T) + 13.728$; monoclinic form given provisionally as $\log P = -(6100/T) + 12.26$; and liquid, $\log P = -2732/T + 6.513$. From the Clausius-Clapeyron equation the heats of vaporization are calcd. as: liquid, 31.5 cal.; octahedral, 77.1 cal.; monoclinic 71 cal.

JAMES M. BELL

Adjusted vapor pressures of zinc and cadmium. C. G. MAIER. *J. Am. Chem. Soc.* 48, 356-64(1926).—The standard free-energy equation $\Delta F_T^\circ = -RT \ln K = \Delta H_0 - \Delta F_0^\circ T \ln T - \frac{1}{2} \Delta G_1 T^2 - \frac{1}{6} \Delta G_2 T^3 - \dots + IT$, has been employed for fusion, sublimation and vaporization of Zn and Cd. From the best available data calcons. are made of Σ , which has been plotted against $1/T$, where $\Sigma = -R \ln K + \Delta F_0^\circ T \ln T + \frac{1}{2} \Delta G_1 T^2 + \frac{1}{6} \Delta G_2 T^3 + \dots$. This plot should be a straight line with slope ΔH_0 and intercept I.

The best possible straight lines are drawn through the points, and the following equations have thus been derived: For Zn, vaporization, $\Delta F_T^\circ = 30,540 + 2.24 T \ln T - 41,760$; sublimation, $\Delta F_T^\circ = 31,515 + 0.10 T \ln T + 0.0015T^2 - 29,932T$; fusion, $\Delta F_T^\circ = 975 - 2.14 T \ln T + 0.0015T^2 + 11.828T$; vapor pressure of liquid, $\log p_{mm} = 12.0013 - 6670/T - 1.1265 \log T$; vapor pressure of solid, $\log p_{mm} = 9.4181 - 6883/T - 0.05029 \log T - 3.277 \times 10^{-4}T$. Similar values for Cd are: vaporization, $\Delta F_T^\circ = 26,645 + 2.50 T \ln T - 43,068T$; sublimation, $\Delta F_T^\circ = 27,050 + 0.46 T \ln T + 0.0013T^2 - 31,301T$; fusion, $\Delta F_T^\circ = 405 - 2.04T \ln T + 0.0013T^2 + 11.767T$; vapor pressure of liquid, $\log p_{mm} = 12.287 - 5819.4/T - 1.2572 \log T$; vapor pressure of solid, $\log p_{mm} = 9.717 - 5907.8/T - 0.4323 \log T - 2.840 \times 10^{-4}T$.

G. C.

Praseodymium, neodymium and hydrogen. A. SIEVERTS AND E. ROELL. *anorg. allgem. Chem.* 150, 261-76 (1926).—An attempt to establish whether the adsorption of H by Pr and Nd leads to solid solns. or definite chem. compds. No reaction between Pr and H takes place at room temp. It starts at 300° on fresh surfaces. The substances obtained form gray or black masses that do not yet melt at 1100°. They decompose in air slowly, forming oxides and nitrides. The conditions of the adsorption resemble generally those with Ce and La, the amts. of H absorbed at temps. between 700° and 1200° being nearly the same. The adsorptive ability of Nd is distinctly smaller than that of Pr. The disson. pressure expts. do not permit a conclusive answer as to whether or not these "hydrides" and those of Ce and La belong to the group of the "salt-like" hydrides of the type of LiH as suggested by G. F. Hüttig (cf. *Z. angew. Chem.* 38, 803 (1925); *C. A.* 20, 1187).

Negative adsorption. VIII. The behavior of kaolin against aqueous solutions of alcohol and some salts. M. A. RAKUZIN AND A. N. NESMEJANOW. *Biochem. Z.* 160, 288-90 (1925); cf. *C. A.* 19, 2213.—In contrast to gelatin, freshly ignited kaolin did not raise the concn. of EtOH either in dil. or concd. solns. Neg. adsorption by kaolin was observed in CuSO_4 solns.

F. A. CAJORI

Viscosity of colloids in presence of electrolytes. N. R. DHAR. *J. Phys. Chem.* 29, 1556-67 (1925).—The greater the hydration of a substance the greater is its viscosity. When the particles of a sol to which an electrolyte is added, adsorb more of the ions of opposite charge than of ions having the same charge, the charge on the sol is decreased, which causes increased hydration with the concomitant increase in viscosity. The viscosity measurements on solns. of gelatin and albumin are explained by assuming that the particles have a natural tendency to disintegrate. Suspended particles of isoelectric gelatin are assumed to disintegrate and consequently, the smaller particles will adsorb more water and the viscosity of the system will increase. The addition of acids or alkalis increases the viscosity as a result of the peptization which accompanies the preferential adsorption of H or OH ions.

HARRY B. WEISER

Equilibrium in colloid systems. O. K. RICE. *J. Phys. Chem.* 30, 189-204 (1926).—The phase rule is deduced in a form directly applicable to colloids and by its use the inference was drawn that equil. exists only when the particles are all of one size or of a few definite sizes both when they are charged and when they are not. The stability of the equil. has been examd. and 2 types of stability, temporary and permanent, have been found. The conditions for stability and the relation between the two kinds have been taken up and the considerations applied to coagulation.

HARRY B. WEISER

Theory of peptization. K. C. SEN. *J. Phys. Chem.* 29, 1533-47 (1925); cf. *C. A.* 19, 2291.—For peptization, a high degree of adsorption and a suitable concn. of electrolyte is necessary. Peptization is sp. for different substances depending on the nature of the adsorbent and of the peptizing agent. Peptization by H ion is less for acids contg. multivalent anions that are strongly adsorbed. Most colloids in aq. soln. are formed by adsorption of an ion or of an ion-peptized colloid; peptization by an undissociated salt is improbable. The stability of a sol depends on the formation of a surface film, which is usually elec. in origin.

HARRY B. WEISER

Effect of temperature of formation on the physical character of hydrous alumina. J. H. YOE. *J. Phys. Chem.* 29, 1419-22 (1925).—Hydrous Al_2O_3 formed at various temps. between 0° and 100° is very gelatinous, the most voluminous preps. resulting at lower

temps. Al_2O_3 pptd. at 66° with NH_4OH and the mixt. heated to boiling, does not give a granular ppt. as claimed by Taylor (C. A. 5, 2050).

Apparent viscosity of colloidal solutions and a theory of neutral colloids as solvated micelles capable of aggregation. J. W. MCBAIN. *J. Phys. Chem.* 30, 239-47 (1926).—The linking together of colloidal particles or micelles to form larger aggregates is caused by bonds of union which are as local and sp. as the processes operative in adsorption or residual affinity. These bonds are loosened by the substitution in them of various chemicals. This generalized form of solvation is the essential factor in gelatinizing and peptizing nitrocellulose and in explaining the apparent viscosity of the resulting systems. The disunion of the bonds between micelles can be accomplished by mech. means only when aggregation is on an excessively coarse scale. H. B. W.

Studies of colloid particles in an alternating-current field. OTTO BLÜH. *Ann. Physik* 76, 177-94; *Physik. Z.* 26, 722-4 (1925).—For the uniform movement of a charged colloid particle in an elec. field the equation $v = BK$ holds, where v is the velocity of the particle, K the potential gradient and B , the mobility of the particle, a const. In an a.-c. field of frequency ν the relation $A\nu = B$, a const., where A is the amplitude of oscillation of the particle, would hold if B is independent of ν . A Bredig Ag sol was observed under the cardioid ultramicroscope, in a cell 6μ thick and provided with 2 Ag electrodes between which an a. c. of 50, 177, or 308 cycles could be imposed. The amplitude of vibration of the same particle could be measured at 50 cycles and again at either 177 or 308 cycles. The av. value of the product $A\nu$ for 85 particles was found to be 7% greater for $\nu = 177$ than for $\nu = 50$, and 15% greater for $\nu = 308$ than for $\nu = 50$. As a tentative explanation of the increased mobility of the particles at higher frequencies it is suggested that the a. c. may tend to separate the charged particles from their "atmospheres" of oppositely charged ions, thus decreasing the effective radius of the particles and consequently the viscous resistance to movement through the dispersion medium. F. L. BROWNE

The color of colloidal silver and mercury. RUDOLF FEICK. *Ann. Physik* 77, No. 8, 573-96 (1925).—(There is a repetition of page nos. 573-588 in vol. 77.) A study of the absorption relations in Ag hydrosols showed that the color cannot be accounted for on the basis of the simple Mie theory. Either the theoretical basis must be extended or concessions must be made in the Maxwell-Garnett theory. The radiation and absorption by colloidal Hg sols predicted by theory were found to be in agreement with the observed facts within the limits of the merely qual. data so far available. From the fact that even in Hg sols Mie's assumptions are obviously very closely verified, it is concluded that the theory comprises the nucleus of the complex problem of the colors of colloids. F. L. BROWNE

The permeability of membranes. L. MICHAELIS. *Naturwissenschaften* 13, 33-42 (1926).—A review of recent work by M., Fujita and Dokan (cf. C. A. 19, 3192, 3274; 20, 321). B. J. C. VAN DER HOEVEN

Structure of gelatin gels. E. O. KRAEMER. *J. Phys. Chem.* 29, 1523-7 (1925).—Hg particles about 200-250 μ in radius were mixed with dil. gelatin systems before gelation. Cinematographic records of the Brownian motion of the particles were made and the magnitudes of the displacement were measured by projection on a ruled screen. Brownian motion was prevented in gels of 0.5% and over, but appeared on gentle warming owing to the breaking down of the gel structure. The latter was not uniform as evidenced by the appearance of Brownian movement in isolated spots, which spread, forming channels. In 0.3% gels a measurable Brownian movement persisted. The observations show that the structure of weak gels is considerably finer than the indicating Hg particles but there is no reason for believing it to be mol. in magnitude. HARRY B. WEISER

The swelling and dispersion of some colloidal substances in ether-alcohol mixtures. E. W. J. MARDLES. *J. Chem. Soc.* 127, 2940-51 (1925).—"A study has been made of the swelling and the dispersion action of ether-alcohol mixts. on colloidal substances. The explanation of the high dispersing action of the mixed liquids must be sought in the cause of the colloidal substances swelling initially to a greater extent in the mixts. than in the liquids taken singly, there being a close correlation between the swelling and the dispersing action. The attraction between a colloidal particle and the mols. of the mixed dispersion medium, due to the presence of mutually reactive groups, whereby complexes are formed, appears to reach a max. with certain combinations of liquids because of the special spatial arrangement and interlocking of the various mols. in the complex resulting from their size, from the relative strengths of their affinity bonds, etc., so that it is necessary in any explanation to consider the relative sp. characters of the liquids and the colloidal substance. With increase in the solvent power of the liquid

mixts. for cellulose nitrate, the change in d . increases and the sols become relatively less viscous. The surface tensions of the organosols are either the same as, or slightly higher than, that of the pure dispersion medium." F. L. BROWNE

Reversible permeability of membranes and its relation to cell metabolism. CHARLES GURCHOT. *J. Phys. Chem.* 30, 83-105(1926).— $\text{Cu}_2\text{Fe}(\text{CN})_6$ membranes are coagulated by low concns. of MeOH , $\text{HC}_2\text{H}_3\text{O}_2$, NaCl , KCl and CaCl_2 , thereby becoming permeable to sugar. A $\text{Cu}_2\text{Fe}(\text{CN})_6$ sol. is flocculated by aq. EtOH , but is peptized by alkalis and H_2O . The coagulation is due to selective adsorption rather than decrease in surface tension and is reversible. The membrane is granular in structure, the particles exhibiting a strong adsorption for water which fills the spaces more or less completely. Bartlow's [*Phil. Mag.* [6], 10, 1; 11, 595(1906)] expts. with alc., Walden's [*Z. physik. Chem.* 10, 699(1892)] expts. with acids and Czapek's [*Ber. deut. botan. Ges.* 28, 159(1910)] expts. with alcs. and acids can be explained by coagulation of the membrane. Intermittent permeability in living membranes is probably a question of reversible coagulation. HARRY B. WEISER

Antagonistic action of ions in the neutralization of sols. H. B. WEISER. *J. Phys. Chem.* 30, 20-33(1926).—The pptn. values of mixts. of electrolytes may be additive or may be greater or less than the additive values. The factors detg. the pptn. concn. of salt pairs are (1) the effect of each pptg. ion on the adsorption of the other, (2) the stabilizing action of the ion having the same charge as the sol and (3) the relatively greater adsorbability of ions at lower concns. The antagonistic action of ions of the same charge is important in raising the critical concns. above the additive value only in case the ions show a marked difference in adsorbability. Variation from the additive relationship with mixts. having a common pptg. ion results only when there is an appreciable difference in the adsorbability of the stabilizing ions. The influence of diln. of sol on the pptn. value of an electrolyte is detd. by the nature of the anion, the cation and the sol. The "general diln. rule" enunciated by Ghosh and Dhar fails to take all of these factors into account and is necessarily limited in its applicability. Strong adsorption of the stabilizing ions of an electrolyte is not essential for "acclimatization" of sols in case there is strong adsorption of the pptg. ion during fractional pptn.; on the other hand, strong adsorption of the stabilizing ion is essential in case the successive diln. of the sol by fractional pptn. is the detg. factor. In either case acclimatization to a greater or less degree is a necessary concomitant of fractional pptn. H. B. W.

Solubility of sodium iodide in ethyl alcohol. F. F. KING AND J. R. PARTINGTON. *J. Chem. Soc.* 129, 20-2(1926).— NaI was made from I_2 , H_2S and Na_2CO_3 , recrystd 3 times from H_2O , and dried at 120° in H_2 . EtOH was dried successively with CaO , AgNO_3 and Ca ; d_4^{25} 0.7851. The soly. found was 42.57 ± 0.3 g. NaI in 100 g. EtOH at 25° . The d_4^{25} of the soln. was 1.037. A. W. FRANCIS

Solubilities of sodium, potassium and calcium ferrocyanides. I. MONICA FARROW. *J. Chem. Soc.* 129, 49-55(1926).—The solubilities and ds. of the satd. solns of the 3 purified salts in H_2O were detd. from 24.9° to 99.7° . The K and Ca salts gave smooth soly. curves, but the Na salt showed a break at 81.5° , indicating transition of $\text{Na}_4\text{Fe}(\text{CN})_6 \cdot 10\text{H}_2\text{O}$ to a lower hydrate. This was confirmed by f. p. and dilatometer. The Ca salt has 11 H_2O and not 12 as formerly supposed. A. W. FRANCIS

The solubility products of mercury halides in water. A. E. BRODSKII AND I. M. STHERSTHEVER. *Z. Elektrochem.* 32, 1-4(1926).—The e. m. f. of the cell $\text{Hg} | \text{Hg}_2(\text{NO}_3)_2(c_0) | \text{KNO}_3 \text{ satd.} | \text{KCl}(c) \cdot \text{Hg}_2\text{Cl}_2 | \text{Hg}$ and the corresponding cell with bromides, were measured for 8 values of c_0 and 2 or 3 values of c . The results are readily extrapolated to $c = 0$, so that the soly. products in water may be calcd. For Hg_2Cl_2 at 11° it is 2×10^{-19} ; at 15° , 3.4×10^{-19} ; at 19° , 5.3×10^{-19} ; at 26.5° , 12.2×10^{-19} ; for Hg_2Br_2 , at 19° , 2.7×10^{-23} ; at 26.5° , 5.7×10^{-23} ; for Hg_2I_2 , at 11° , 1.7×10^{-30} ; at 15° , 4.9×10^{-30} ; at 19° , 11.8×10^{-30} ; at 26.5° , 63×10^{-30} . The values for Hg_2I_2 are obtained indirectly from the e. m. f. of the cell $\text{Hg} | \text{Hg}_2\text{Cl}_2 \cdot \text{KCl}(0.1N) | \text{Kl}(0.1N) \cdot \text{Hg}_2\text{I}_2 | \text{Hg}$, and the soly. product of Hg_2Cl_2 . B. H. CARROLL

The influence of minute traces of water on the equilibria of solution. I. ERNST COHEN AND W. D. J. VAN DOBBENBURGH. *Proc. Acad. Sci. Amsterdam* 28, 702(1925) — See C. A. 20, 137. E. J. C.

Unstable states of solutions of sodium behenate. MARY E. LAING. *J. Chem. Soc.* 127, 2751-5(1925).—The stable form of Na behenate at room temp. in concns. between 0.05 and 0.5 N is a hard, white curd. By heating to about 88° the curd melted to a fairly mobile, milky liquid. Rapid cooling produced a clear, very mobile liquid which was stable for a few hrs. Detns. were made of the p_H , elec. cond., and f. p. lowering of the solns. The unstable, mobile liquids are hydrolyzed to an abnormally large

extent. The largest constituent is neutral undissocd. colloid, the next largest being colloidal acid Na soaps with the equiv. quantity of free NaOH. There is a very small proportion of dissocd. soap.

F. L. BROWNE

Stability of solutions of carbon dioxide. A. KLING AND A. LASSIEUR. *Compt. rend.* 182, 130-1 (1926).—Ammonia- or base-free distd. H_2O , satd. with CO_2 , decomposes readily and completely, the p_H value dropping to that of highly purified distd. H_2O , *i. e.*, 5.8. Boiling hastens the decompn. No direct test, however, could be given to show the difference between purified water and 0.00001 N CO_2 soln., both having a p_H of 5.8.

P. B. P.

Influence of solubility. I. The temperature coefficients. F. OLIVERI-MANDALA. *Gazz. chim. ital.* 55, 759-68 (1925).—The application of van't Hoff's isochore to certain data selected from the literature leads to the following erroneous deductions: (1) that the increase in soly. of Br in solns. of KBr and that of I in aq. solns. of KI is not due to a chem. phenomenon on the basis of the smallness of q or that because of the small affinity between the halogen and the dissolved substance the compds. supposed to exist in aq. soln. are very unstable; (2) that caffeine forms addn. compds. in H_2O soln. with NaOBz that are much more stable than the preceding ones as judged by the high values of q ; (3) that NH_3 forms addn. compds. with chlorides and alkali carbonates in aq. soln.; (4) that salicylic acid forms very stable addn. compds. with *d*-glucose because of the high value of q . The results lead O.-M. to conclude that van't Hoff's isochore formula cannot be applied when one wishes to calc. the heat of soln. in cases of influence on soly. and consequently inaccurate results are obtained by using the magnitude of the heat of soln. as a criterion of chem. action between solute and the solvent in question. II. The molecular coefficients of solubility. *Ibid* 769-74.—The influence of soly. is expressed by the following formulas: (1) $(l_0 - l)/l = 1/n$ and (2) $(l - l_0)/l_0 = 1/n$ where l_0 and l represent the soly. of the compd. in H_2O and in the soln. and n indicates the concn. of said soln. With formula (1) O.-M. calcs. the mol. lowering of soly. and with (2) the mol. increase in soly. The results obtained in this way complete the previous paper and show: (1) that in phenomena dealing with influence on soly. it may be that with non-electrolytes as well as with electrolytes the ratio (concn. of dissolved compd.: concn. of soln.) is in general a function of the concn. of the soln., *i. e.*, it does not follow the law of mass action. The type of such functions is different not only in phenomena of the same nature, *e. g.*, in the cases of soly. of halogens in solns. of halides, but varies also in the same cases in certain limits of concn. Thus while data of the soly. of I in dil. solns. of KI (Noyes, Seidensticker, *Z. physik. Chem.* 27, 357 (1898)) show that the ratio I:KI is independent of the concn. of KI, the data of Weith and Dossios on more concd. solns. show that this ratio is an exponential function of the KI concn. In the field of org. chemistry no regularity has been observed in the phenomenon of influence of soly. in the sense that in some cases the ratio between the concn. of substance added and that of the soln. is independent of the concn. of the soln. and in other cases increases or diminishes with increase of concn. III. Quinine hydrochloride and antipyrine. E. OLIVERI-MANDALA AND E. CARLI. *Ibid* 774-82.—In this paper a well-known case of influence on soly., *i. e.*, the influence of antipyrine (I) on the soly. of basic quinine hydrochloride (II) in H_2O was examd. in detail. Basicine (a com. mixt. of II and caffeine) is very sol. in H_2O and has a greater therapeutic action than II alone and fails to give rise to the secondary clinical phenomena characteristic of II alone. Other similar instances are cited. Recently, Schepelmann (*J. pharm. chim.* 5, 266 (1912)) used a soln. of I + II as a local anesthetic; the presence of I prevents the bad effects arising from the injection of II alone. It is not known at present whether or not in these cases combination occurs between the 2 compds. in soln. Expts. were performed to det. if the increase in soly. of II in H_2O in aq. solns. contg. I was due to the formation of a mol. complex. The methods of cryoscopy and the detns. of the soly. coeffs. at various temps. were used. The results show that the soly. of II in H_2O is considerably increased by the addn. of I and that the ratio between the soly. of II and the concn. of I (coeff. of soly.) increases slightly with increase of the concn. of I. The ratio of the concn. of II to I is nearly independent of the temp., *i. e.*, the heat of soln. of II in H_2O is nearly equal to that of II in solns. of I and on the basis of deductions in the first paper this means that II does not act chemically upon I because the thermal effect is nearly zero. The cryoscopic results, however, show clearly that I combines with II in aq. soln. to form nondissocd. complex salts. IV. Acetanilide-antipyrine, acetanilide-pyramidone. E. OLIVERI-MANDALA AND F. FORNI. *Ibid* 783-8.—From the expts. on the soly. of these pairs in H_2O it is concluded that so far as the influence of antipyrine on the soly. of acetanilide in H_2O (which is considerable) is concerned this is not due to combination of the 2 compds., if the temp. coeff. of soly. is taken as the criterion. In the case of pyramidone, which

exercises a small influence on the soly. of acetanilide in H_2O , there is a more pronounced tendency to the formation of such complex as judged by the same criterion.

E. J. WITZEMANN

The inter-ionic attraction theory of ionized solutes. V. Testing of the theory by solubility experiments at higher temperatures. W. P. BAXTER. *J. Am. Chem. Soc.* **48**, 615-21 (1926); cf. *C. A.* **19**, 3408.—The soly. of $AgIO_3$ has been detd. at 75° in pure H_2O and in the presence of different salts in various concns. The results conform, up to an ionic strength of 0.01 *M*, with the limiting equation of Debye and Hückel [*C. A.* **17**, 2665; Debye, *C. A.* **18**, 190, 3514], and supplement the earlier work of Bronsted and La Mer [*C. A.* **18**, 1602] in affording a verification of the ion-attraction theory at very small concns. The results also afford a confirmation of the theoretical effect of varying the temp. and of the concomitant variation of the dielec. const. when H_2O is the solvent.

PER K. FRÖLICH

The ionic activity product of water in glycerol-water mixtures. JAMES COLVIN. *J. Chem. Soc.* **127**, 2788-92 (1925).—In mixts. of glycerol and H_2O contg. up to 40% glycerol, detns. were made of (1) the H -ion concn. by means of the H_2 electrode and (2) the OH -ion concn. by means of the Donnan-Allmand HgO electrode. The dissoc. const. of H_2O remains const. over the range of concn. studied. The ionic activity product does not exhibit appreciable change.

F. L. BROWNE

Hydration of strong electrolytes, the viscosity of their aqueous solutions and the dilution law. J. N. SUGDEN. *J. Chem. Soc.* **129**, 174-97 (1926).—The hydration of sucrose and some strong electrolytes has been detd. from the distribution of $AcOH$ between their aq. solns. and amyl alcohol. The results indicate that the hydration is independent of diln. and is an additive property which may have either a pos. or a neg. value. The concns. employed were as high as 2 *N*. A modified hydration theory is suggested according to which only cations are hydrated while anions depolymerize the solvent mols. The first process tends to decrease and the second to increase the activity of the water. Hydration is, therefore, a composite effect, the salts having neg. hydration nos. being those in which the influence of the anion predominates. Solns. of such salts have abnormally high vapor pressures. The hydration theory has been correlated with viscosity phenomena and a semi-empirical equation established by means of which hydration values can be calcd. from viscosity data. A hydration correction has been applied to calcns. of the degree of dissocn. of strong electrolytes from f. p. measurements and evidence is adduced in favor of a cube-root diln. law $(1 - \alpha) = K\sqrt[3]{n}$. Many salts have been shown to obey the law with great exactness and those which do not do so are extreme cases in which the application of the correction is least certain. Corroborative evidence for the new theory has been obtained from a consideration of the cond. ratios of a no. of strong electrolytes.

JAMES M. BELL

Hydrolytic dissociation curves. J. O. W. BARRATT. *Biochem. J.* **19**, 875-81 (1925).—B. has collected together some of the equations and curves dealing with interactions between a weak base and a strong acid and *vice versa*.

BENJAMIN HARROW

Activity coefficient of hydrochloric acid in concentrated solutions of strong electrolytes. H. S. HARNED. *J. Am. Chem. Soc.* **48**, 326-42 (1926).—Measurements of cells of the type: $H_2 | HCl (m_1) MCl (m_2) | HgCl | Hg$, where $m_1 + m_2$ is const., have been made. At const. total molality up to 3*M* the logarithm of the activity coeff. of the acid varies linearly with the acid concn. Revised measurements of the above cells contg. acid at 0.01 and 0.1*M* and chlorides at various concns. are presented. Fifteen series of results with univalent electrolytes may be calcd. within narrow limits from Hückel's approx. equation (*C. A.* **19**, 1649). From the data on the mixts. the consts. of the individual electrolytes were computed by Debye and Hückel's theory (*C. A.* **17**, 2665) and were shown to be very nearly the same as the consts. derived from data on the individual electrolytes. The activity coeffs. of $CaCl_2$, $SrCl_2$, $BaCl_2$ are calcd. by Hückel's equation and the activity coeff. of HCl in these salt solns. may be calcd. These calcns. show excellent agreement between observed results and the general theory of Debye and Hückel. In fact, nothing seriously contradictory to the general theory has developed from the numerous results in chloride solns. The theory cannot, however, be applied to solns. of alk. hydroxides without the introduction of another factor.

JAMES M. BELL

The application of the Nernst osmotic theory to non-aqueous solutions. A. E. BRODSKII. *Z. Elektrochem.* **32**, 5-6 (1926).—Measurements on the cell $Hg | Hg_2Cl_2 \cdot KCl (c_1) | KCl (c_2) \cdot Hg_2Cl_2 | Hg$ and the corresponding cell with bromides, in water, 50% $EtOH$ and abs. $MeOH$, vary unaccountably from the values calcd. by the theory of Nernst (*Z. physik. Chem.* **4**, 150 (1889)).

B. H. CARROLL

Hydrogen electrode studies of the precipitation of basic chromates, borates and carbonates. H. T. S. BRITTON. *J. Chem. Soc.* 1926, 125-47.—The H-ion concns., which govern the pptn. of basic salts contg. weak acid radicals are the same as those at which the hydroxides are pptd. (cf. *C. A.* 20, 26). The following chromates, borates and carbonates were studied: Th, Al, Cr, Be, Zn, the following chromates: Nd, Sa, Y, Co, Ni: and the following borates and carbonates: Zr, Mn, Mg. Cases of delayed pptn. occurred with Zr and Th solns. The precipitability of the different bases as basic salts depends on the capacity of the precipitant to produce the p_H at which the hydroxide is pptd. In cases where this p_H is only just attained the pptn. is partial. In several cases the conditions for the pptn. of normal salts have been discussed. The mode of dissocn. (*C. A.* 19, 225) of chromic acid has been shown to account for the action of alkali metal chromates in pptg. basic salts. JAMES M. BELL.

Formation and growth of silver nuclei in the decomposition of silver oxalate. J. Y. MACDONALD AND C. N. HINSHELWOOD. *J. Chem. Soc.* 127, 2764-71(1925).—A sensitive method is described for making direct measurements of the instantaneous rate of reaction in a chem. change where gas is evolved and an account is given of its application to the investigation of certain interesting phenomena relating to the thermal decompn. of $(CO_2Ag)_2$, which takes place according to the equation $(CO_2Ag)_2 = 2Ag + 2CO_2$. The rate of this reaction is governed entirely by the formation and growth of Ag nuclei in the space lattice of the oxalate crystals. These processes are sensitive to the presence of adsorbed ions and to O. The latter has a very pronounced poisoning effect on the Ag nuclei. It is thought that the nuclei of Ag are formed at the crystal surface rather than in the interior. E. P. WIGHTMAN.

The oxidation of oxalic acid by potassium permanganate. GEORG SCHEFF. *Biochem. Z.* 160, 390-7(1925).—If $Na_2C_2O_4$ and H_2SO_4 are allowed to react with an excess of $KMnO_4$ at 70° for long times more $KMnO_4$ is reduced than can be accounted for on the basis that 3 mols. $KMnO_4$ are reduced by 5 mols. $H_2C_2O_4$. If the duration of the reaction is always the same the amt. of reduced $KMnO_4$ is proportional to the $H_2C_2O_4$ present. F. A. CAJORI.

Principles and methods of catalytic investigation. H. S. TAYLOR. *Can. Chem. Met.* 10, 35-8(1926).—An address. E. J. C.

The catalytic decomposition of hydrogen peroxide in an acid chlorine-chloride solution. R. S. LIVINGSTON AND WM. C. BRAY. *J. Am. Chem. Soc.* 48, 405-6(1926).—Certain corrections are made in the derivation of equations of a previous paper (*C. A.* 19, 3411). These do not, however, affect any of the conclusions. C. C. DAVIS.

Catalytic activation of titania. W. A. RUDISILL AND C. J. ENGELDER. *J. Phys. Chem.* 30, 106-13(1926).—Factors affecting the catalytic activity of TiO_2 were detd. by passing the vapors of $EtOH$ over various prepn. at 350° and noting the vol. and compn. of the gaseous products of decompn. With increasing temp. of ignition, the activity and C_2H_4 production decreased. To produce a good dehydrating catalyst the ignition temp. must be low. Catalysts made by pptg. from sulfate or chloride solns. and by hydrolysis were most efficient, while those pptd. from oxalate were the least active, gave the lowest % of C_2H_4 and the highest % of C_2H_6 . The activity increases with the degree of fineness of the catalyst. A prepn. from sulfate soln. was very active after 10 hrs.' use. HARRY B. WEISER.

Studies of dynamic isomerism. XX. Amphoteric solvents as catalysts for the mutarotation of the sugars. T. M. LOWRY AND I. J. FAULKNER. *J. Chem. Soc.* 127, 2883-7(1925); cf. *C. A.* 19, 2642.—"Pyridine, which is inactive when dry, gives, when mixed with about twice its wt. of H_2O , a max. velocity of mutarotation which is about 20 times as great as the velocity for solns. of the same sugars (glucose and tetramethylglucose) in pure H_2O . Cresol, like pyridine, has no appreciable catalytic properties when H_2O is not present, showing that acids and bases may alike be rendered ineffective if used in the absence of H_2O . Mixts. of cresol and pyridine, each sufficiently dry to give only a negligible velocity of mutarotation, when mixed in the proportion of about 2 parts of cresol to 1 part of pyridine, are again about 20 times as active as H_2O in promoting the mutarotation of tetramethylglucose." These facts lead to the conclusions that "(1) it is impossible for a proton to wander directly from one position to another within the mol. of sugar and (2) in order to effect this transfer, it is necessary to provide a medium into which a proton can escape from the sugar and from which a proton can be provided to replace the proton thus lost by the sugar." F. L. B.

Fourth report of the Committee on Contact Catalysis of the Division of Chemistry and Chemical Technology of the National Research Council. H. S. TAYLOR. *J. Phys. Chem.* 30, 145-71(1926).—The subject of contact catalysis is reviewed with special regard to the progress made during the last 4 years. In discussing the results of recent

research an attempt is made to interpret such data in light of Taylor's theory. According to this the properties of the contact agent are to be differentiated from the bulk properties of the substance of which the catalyst is composed, while the properties of the individual atoms or mols. of the catalyst, with the changes in these properties induced by position and arrangement in the catalyst particle, are of importance in catalytic change. The ensuing problems for future research along these lines are outlined.

PER K. FRÖLICH

Contact catalysis. A. MITTASCH. *Ber.* 59B, 13-36(1926).—Review of catalysis from the days of Döbereiner and up to the present with emphasis upon the theoretical and practical aspects of contact catalysis, especially of gas reactions catalyzed by solid materials. Numerous references. In reviewing the various theories of catalysis M. comes to the conclusion that the theory of intermediate-compd. formation is the most plausible one in consideration of the fact that there is no real distinction between adsorption and compd. formation. This being admitted, there is no fundamental difference between catalytic and non-catalytic reactions. Understanding of the mechanism of catalysis, however, is limited and can only progress with the study of the structure of the atom and the mol. on the one hand, and with studies in the field of reaction kinetics on the other hand.

PER K. FRÖLICH

Equilibrium in the system arsenic pentoxide, barium oxide, water (acid section). S. B. HENDRICKS. *J. Phys. Chem.* 30, 248-53(1926).—The stable compds. in the acid division of the system BaO , As_2O_5 , H_2O at 30° are $\text{BaHAsO}_4 \cdot \text{H}_2\text{O}$, $\text{BaH}_4(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$, and $3\text{As}_2\text{O}_5 \cdot 5\text{H}_2\text{O}$. Alkali treatment of $\text{BaHAsO}_4 \cdot \text{H}_2\text{O}$ give hydrous $\text{Ba}_3(\text{AsO}_4)_2$.

HARRY B. WEISER

Elimination of salt from sea-water ice. W. G. WHITMAN. *Am. J. Sci.* 11, 126-32(1926).—Sea-water ice contg. entrapped salt will eliminate the salt under the influence of a temp. gradient through the ice. The salt diffuses as brine through the ice toward the warmest part of the ice-cake. Below the eutectic temp., -21° , diffusion will not take place. Expt. shows that the process of diffusion will occur independently of gravity. The phenomenon is satisfactorily explained by the effect of temp. upon the equilibrium relationship between ice and salt water.

R. J. H

Heterogeneous equilibria between the sulfates and nitrates of sodium and potassium and their aqueous solutions. I. The ternary systems. M. A. HAMM. *J. Chem. Soc.* 1926, 199-205.—The available published data on the ternary systems at 25° and at 90° have been completed in this paper. (1) System $\text{K}_2\text{SO}_4\text{--KNO}_3\text{--H}_2\text{O}$ at both temps. belongs to the simplest type with neither hydrates nor double salts. (2) System $\text{KNO}_3\text{--NaNO}_3\text{--H}_2\text{O}$ at 90° is of the same type. (3) System $\text{K}_2\text{SO}_4\text{--Na}_2\text{SO}_4\text{--H}_2\text{O}$ at 25° has three solid phases, $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, K_2SO_4 and glaserite contg. Na_2SO_4 in solid soln. At 90° the solids are Na_2SO_4 , K_2SO_4 and glaserite contg. Na_2SO_4 in solid soln. At both temps. glaserite is decomposed by water. (4) System $\text{Na}_2\text{SO}_4\text{--NaNO}_3\text{--H}_2\text{O}$ at 25° has the solid phases, $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, Na_2SO_4 , $\text{Na}_2\text{SO}_4 \cdot \text{NaNO}_3 \cdot \text{H}_2\text{O}$, which is darapskite, and NaNO_3 . No evidence of the double salt $3\text{NaNO}_3 \cdot 4\text{Na}_2\text{SO}_4$ of Massink (*C. A.* 11, 3184) was found. At 90° the only solid phases are the anhydrous salts. II. The quaternary system, $\text{H}_2\text{O--Na}_2\text{SO}_4\text{--NaNO}_3\text{--K}_2\text{SO}_4\text{--KNO}_3$. *Ibid* 206-14.—In addition to the solid phases at 25° found in the ternary systems (cf. above) a new solid of unknown comp. was encountered. At 90° only the anhydrous salts and glaserite were found.

JAMES M. BELL

Influence of minute traces of water on solubility equilibria. II. F. COHEN AND S. MIYAKE. *Verslag Akad. Wetenschappen Amsterdam* 34, 933-8(1925); cf. *C. A.* 20, 137.—Min. traces of H_2O increase the soly. of salicylic acid in C_6H_6 and CHCl_3 and of *o*-nitrobenzoic acid in CHCl_3 . No influence could be detected in the salicylic acid- CCl_4 and anthracene- C_6H_6 equil.

G. CALINGAERT

Influence of pressure on the equilibrium of binary systems. II. N. A. PUSHIN. *Z. phys. Chem.* 118, 447-59(1925); cf. *C. A.* 20, 1021.—Data are given showing the influence of pressure on the T - x diagram of urethan-benzene. The eutectic point, situated at 4.2, 4.4% (by weight) urethan for 1 atm. rises steadily with pressure and is at 59.4° , 80% urethan for 4050 kg./sq. cm. pressure. The dt/dp values vary for the eutectic mixt. from 0.0220 at $p = 500$ kg./sq. cm. $t = 15.1^\circ$ to 0.0088 at $p = 3500$ kg./sq. cm. and $t = 54.8^\circ$. The theoretical conclusions of the first article were confirmed.

B. J. C. VAN DER HOEVEN

Elements with anomalous valences. M. GOMBERG. *Chem. Reviews* 2, 301-14(1925).—A review from which G. derives the viewpoint that most elements are capable of existing in 1 or more states of anomalous valence.

G. CALINGAERT

Technical expressions in Werner's theory of inorganic complex salts. THEODOR STRECHER. *Z. angew. Chem.* 39, 36-8(1926).—One of the most serious obstacles to a better

understanding of Werner's coördination theory, is the clumsy nomenclature used, S objecting to such terms as "secondary valence" and "coördination numbers." To avoid the necessity of designating N as both quinquevalent and tervalent, S. suggests the substitution of "ortig" for "wertig" in speaking of coördination nos., and in forming NH_4Cl from NH_3 , N would not be spoken of as going from the tervalent to the quinquevalent conditions, but from the "dreiertigen" or 3 place to the "vierortigen" or 4 place condition, with no change in "wertigkeit" or valence. S. also suggests a change in nomenclature when referring to org. bases and their addn. salts such as R, R.HCl, $(\text{R.H})_2\text{SO}_4$, etc. He suggests the use of the ending "ium" as in ammonium chloride. Thus with the base Quinine, we would have for R.HCl, "quininium chloride," for $(\text{R.H})_2\text{SO}_4$, "quininium sulfate," and for RCH_2Br , "quininemethylum bromide."

H. STOERTZ

Phase diagrams of binary systems containing arsenic tribromide as one component. N. A. PUSHIN AND S. LÖWY. *Z. anorg. allgem. Chem.* 150, 167-74(1926).—Phase diagrams have been taken of binary systems contg. AsBr_3 as one component and SbBr_3 , $\text{PhNH}_2\cdot\text{HCl}$, resorcinol, PhOH , α -naphthol or ethylurethan, resp., as the other. The system AsBr_3 - SbBr_3 gives an uninterrupted series of solid solns. AsBr_3 forms with $\text{PhNH}_2\cdot\text{HCl}$ a mol. compd. which decomposes above 133° . The binary systems AsBr_3 with resorcinol, phenol, α -naphthol and urethan, resp., form only mech. mixts. in the cryst. state. The 3 latter show characteristic eutectic points. EMIL KLARMANN

The systems formed by certain inorganic compounds with liquid sulfur dioxide. P. A. BOND AND H. T. BRACH. *J. Am. Chem. Soc.* 48, 348-56(1926).—With liquid tetrahalides (SnBr_4 , CCl_4 , SnCl_4 and TiCl_4), SO_2 forms mixts. which are but partially miscible at low temps. The relative positions of the *crit. mixing temps.* are in accordance with those which might be predicted from the polarities, internal pressures and m. ps. of the compds. involved. In no case did the formation of a compd. occur above the m. p. of SO_2 , though this might have taken place where solid phases were present. The *crit. soln. temp.* of SnBr_4 - SO_2 was 48.6° , of CCl_4 - SO_2 was -29.3° and of TiCl_4 - SO_2 was 11.9° . SnCl_4 - SO_2 formed an unusual case, in that the curve for the 2-liquid-phase system lay completely below the curve for the soly. of solid SnCl_4 in SO_2 over the same compn. range. A metastable binary-liquid system was found for SnCl_4 - SO_2 . C. C. DAVIS

The reaction of sulfite with unsaturated compounds. ERIK HÄGGLUND AND ANDERS RINGBOM. *Z. anorg. allgem. Chem.* 150, 231-53(1926).—While this reaction has been studied exhaustively from the preparative standpoint, little was known about its mechanism, although some information on the nature of the ethylene double bond was to be expected. H. and R. studied, as a kinetic reaction, the addn. of sulfite to the fol' wing unsatd. compds.: acrylic, crotonic cinnamic, triphenylacrylic, sorbic, fumaric, maleic, citraconic and mesaconic acids. The temp. of reaction was 80° . The amt. of sulfite bound by the resp. compd. was detd. by titration of the excess with 0.1 N I_2 . It was established that none of the compds. reacted with the I_2 -soln. The addn. of sulfite was found to be a bimol. reaction, except in the case of acrylic acid. The latter reacts much faster than any other acid. Only bisulfite reacts while the neutral sulfite does not take part in the reaction. The *cis*-form reacts more easily than the *trans*-form. The acid salt of fumaric acid reacts faster than the neutral one while the acid salt of maleic acid reacts much more slowly than the neutral. There is a conformity with Werner's theory of the changing valence of the C atom, the reactivity depending on the wt. of the radical attached to the C atoms which carry the double bond. The same phenomenon was observed by Schlenk and Mark (*C. A.* 17, 755) in the bromination of unsatd. compds. Thus ethylene absorbs Br very eagerly, stilbene much more slowly, while no Br is taken up by tetraphenylethylene. EMIL KLARMANN

A new form of the mass-action law for condensed and two-phase systems. RICHARD LORENZ. *Naturwissenschaften* 13, 81-2(1926); cf. *C. A.* 20, 863.—For condensed systems, molten salts and metals, L. and van Laar have derived a mass-action law (*C. A.* 19, 3412) of the form $x(1-y)/(1-x)y = Ke^u$, the first four terms being concns., K a const., $u = (\alpha/RT)[\{x^2 - [(1-x)^2/(1+r)]\}/(1+rx)^2] - (\alpha'/RT)[\{y^2 - [(1-y)^2/(1+r')]\}/(1+r'y)^2]$. The last term is calcd. from a and b functions of the components as indicated by van Laar (die Zustandsgleichung). An example of application of this law is now given in the $\text{Cd} + \text{PbCl}_2 = \text{CdCl}_2 + \text{Pb}$ equil. Whereas the *C* const. according to the classical mass-action law runs from 110 to 11.56 in a certain range, the new K is a very satisfactory const. B. J. C. VAN DER HORVEN

The potentials of cadmium-magnesium alloys. G. VINOGRADOV AND G. PETRENKO. *Z. anorg. allgem. Chem.* 150, 254-7(1926).—An attempt to ascertain whether potentiometric measurements are suited for establishing the existence of a chem. compd. in an uninterrupted series of solid solns. Previous studies of the phase diagram, the elec.

cond. and the hardness of alloys of this system showed that a compd., CdMg, exists in 2 modifications with the point of transition lying at 245.5° . V. and P. measured the potentials of the combination Cd-Mg alloy | 1*N* MgSO₄ | Mg. Somewhat different results were obtained with quenched and slowly cooled alloys. A distinct discontinuity in the potential curve indicated the existence of a compd. with 50 atom % Cd.

EMIL KLARMANN

Calorimetric researches. IX. The heat of combustion of *d*- and mesotartaric acids, racemic acid and a number of their derivatives. J. COOPS and P. E. VERKADE *Rec. trav. chim.* **44**, 983-1011 (1925). (In English.)—The thermochem. investigations on the stereoisomeric tartaric acids and their derivs. are still in the early stage. So far only heats of combustion have been detd. for cryst. compds. and only a few derivs. have been investigated. The app. and method were previously described (V., C. and Hartman, *C. A.* **16**, 3578; **19**, 2445). The detn. of the heat capacity of the calorimetric system was previously described (V. and C., *C. A.* **17**, 3638; **19**, 205). All heats of combustion detd. hold for an isothermal reaction at the initial temp. of the measurements, *i. e.*, 19.5° . The mean heat of combustion of *d*-tartaric acid is 1840.8 cal.₁₈ of racemic acid 1826.8 cal.; of meso-tartaric acid 1844.9 cal.; of NH₄ *d*-bitartrate 2050.5 cal.; of NH₄ biracemate 2037.4 cal.; of NH₄ mesobitartrate 2047.5 cal.; methylammonium *d*-bitartrate 2808.7 cal.; the biracemate 2798.2 cal.; the meso-bitartrate was unsuited for this detn. on account of its extraordinary hygroscopicity; ethylammonium *d*-bitartrate 3413.2 cal.; the biracemate 3401.4 cal.; the meso-bitartrate could not be purified; aniline α -bitartrate 4442.6 cal.; aniline biracemate 4434.4 cal.; the aniline meso-bitartrate could not be purified; benzylammonium biracemate 4785.3 cal.; the meso-bitartrate 4791.7 cal.; the *d*-bitartrate gave unsatisfactory results; *d*-tartramide 2889.4 cal.; meso-tartramide 2885.1 cal.; *d*-tartaric diethylamide 5213.3 cal.; the *dl*-compd. 5214.3 cal.; the meso-compd. 5219.4 cal. The 2 following equations may be derived from the heats of combustion of *d*- and meso-tartaric acids and of racemic acid: $\Delta(d-dl) = 2.1 \pm 0.1$ cal. and $\Delta(m-d) = 0.6 \pm 0.1$ cal. both at 19.5° . $\Delta(d-dl)$ could be called the heat of racemization of solid *d*- (or *l*-) tartaric acid. From data on the mol. heat of soln. values for the difference had previously been calcd. by other workers which are practically identical with those obtained from the heats of combustion. In any case this difference is only about 0.8% of the measured heats of combustion. The difference $\Delta(m-d) = 0.6$ is not a true comparison between the energy contents of these 2 acids which would have to be measured while these compds. were in the state of non-associated vapor, which is of course impossible. Both in the cryst. state and in dil. aq. soln. the sym. intramol. inactive acid has a greater energy content than the asym. optically active acid and this difference is doubtless connected with their different spatial grouping. In 1889 Stohmann, Kleber and Langbein said that of isomeric acids, that which possesses the largest dissocn. const. also possesses the largest heat of combustion. This rule does not always hold for isomers having a closely related constitution. meso-Tartaric acid has a larger heat of combustion yet a smaller dissocn. const. than *d*-tartaric acid. Examn. of the data shows that there is no question of a const. group value for the substitution of H with OH. Under no consideration can the heat of combustion be regarded as an additive quantity which may be calcd. by means of similar group values. A comparison of the data shows that for the 4 pairs *d*-bitartrate and biracemate derivs. studied the heat of combustion of the former is 2.0-2.3 cal. higher than for the latter, suggesting certainly that these compds. at 20° are racemic like racemic acid itself. This is not true for the diethylamide derivs. The soly. of these compounds in 96% EtOH at 17.5° showed marked differences; the racemic acid deriv. is the more sol. compd. In a satd. soln. of the latter compd. *d*-tartaric diethylamide is readily sol. The racemic acid deriv. is, therefore, certainly a racemic compd. Stohmann has stated the rule that with isomeric compds. those having the highest m. ps. should have the lowest heat of combustion. This is true in 2 of the 4 pairs investigated in this paper. Calcns. can be made from the data given regarding alterations in the heats of combustion of a substance on replacing one group with another but such calcns. will be made in Paper XII on the basis of more extensive material. E. J. W.

Experimental determination of the thermal conductivities of gases. H. GREGORY and C. T. ARCHER. *Proc. Roy Soc. (London)* **110A**, 91-122 (1926).—By means of the method of having a hot wire mounted coaxially in a glass tube G. and A. have detd. the thermal cond. *K* of dry, CO₂-free atm. air and dry H. Using values exptly. detd. they have been able to make correction for the losses due to convection, radiation, conduction along the leading wires and for the glass wall. Temps. were measured by using each pair of Pt wires in the app. as a compensated Pt thermometer. Readings were taken by means of a Callender-Griffiths bridge. Changes in pressure (0.001-

760 mm.) were obtained by means of a motor-driven Gaede mol. pump. Pressures below 0.5 cm. were read by using a McLeod gage. For air $K_{12.002} = 0.0604$, $K_{9.479} = 0.0600$, $K_{7.437} = 0.0596$, $K_0 = 0.0583$; for H $K_{4.218} = 0.04088$, $K_{3.289} = 0.04079$, $K_{2.355} = 0.04068$, $K_0 = 0.04043$. The % error $K_{(air)}$ for the lowest temp. gradient has been calcd. to be 0.33%, for the highest 0.27%. Diagrams of the app. and elec. connections are given.

E. R. SCHIERZ

Thermal decomposition of sulfates. GERMAINE MARCHAL. *J. chim. phys.* 22, 559–82(1925); cf. *C. A.* 19, 3201; 20, 346.—(1) Previous work on the decompn. of $NiSO_4$ indicates that dissoen. begins at 690° , and at 840° the pressure reaches 1 atm. M. finds 12.6 mm. at 700° , 114 mm. at 800° and 1030 mm. at 900° for the total pressure. The equil. is attained very slowly, requiring at least 1 hr. at 890° . The heat of dissoen. calcd. from the pressure data is 62.8 cal. (2) Previous data on $CaSO_4$ are not concordant. M. finds pressure = 11.5 mm. at 700° , 38 mm. at 800° , 291 mm. at 900° and 1441 mm. at 1000° . Heat of dissoen. is calcd. = 50.6 cal. (3) $CdSO_4$ dissoen. pressure = 15.2 mm. at 780° , 770 mm. at 1060° and 2345 mm. at 1120° . (4) $Ga_2(SO_4)_3$ is the most easily decomposed of the sulfates studied. The dissoen. pressure reaches 12 mm. at 560° , 625 mm. at 680° and 885 mm. at 700° . (5) $MnSO_4$ decomposed according to the scheme $3MnSO_4 = Mn_3O_4 + 2SO_3 + SO_2$. The total dissoen. pressure is 18.3 mm. at 820° , 527 mm. at 1000° and 2000 mm. at 1100° . (6) $Ag_2SO_4 = 2Ag + O_2/2 + SO_3$ represents the decompn. of this salt. The total pressure = 14.6 mm. at 820° , 51.0 mm. at 900° , 203 mm. at 1000° and 708 mm. at 1100° . The total pressure at equil. is the pressure exerted after a balance has been established among the dissoen. products according to the equation $2SO_3 = 2SO_2 + O_2$ (cf. *C. A.* 20, 346). M. uses the term "beginning of dissoen." loosely, meaning the temp. at which the total pressure reaches approx. 10 mm. Hg. *Ibid* 23, 38–60(1926).—Dissoen. pressure of $CaSO_4$, the effect of addn. of SiO_2 , Al_2O_3 , kaolin and Fe_2O_3 on its decompn., and some possible industrial applications are considered. The total dissoen. pressure of pure $CaSO_4 = 8$ mm. at 1000° and 67.7 mm. at 1200° . At these temps. the evolved gases dissoen. almost completely to SO_2 and O_2 . Addn. of any of the above named substances increases the dissoen. pressure, the effect of kaolin being the most marked. In presence of SiO_2 , whether amorphous, or powdered cryst., pressure = 10.5 mm. at 940° and 817 mm. at 1280° . With Al_2O_3 added, pressure = 9.0 mm. at 1000° and 200 mm. at 1280° . With kaolin ($Al_2O_3 \cdot SiO_2$) the pressure reaches 173 mm. at 1000° and 1070 mm. at 1170° . The action of Fe_2O_3 is slightly greater than that of Al_2O_3 , pressure = 12.5 mm. at 1000° and 273 mm. at 1280° . Cr_2O_3 acts very irregularly, apparently absorbing all the SO_2 formed, so that the gases evolved are almost pure O_2 . It should be possible to utilize the above facts industrially in production of H_2SO_4 .

F. C. KRACEK

The dissociation and specific heat of chlorine and hydrochloric acid gas at high temperatures. KURT WOHL AND WALTER KADOW. *Z. physik. Chem.* 118, 460–74 (1925).—Improved methods of calcn. are applied to W.'s old data on explosions of $H_2 + Cl_2$ in presence of excess H_2 , Cl_2 or HCl , and to some new data confirming results already obtained (*C. A.* 18, 3522). The heat of dissoen. of Cl_2 is $57,000 \pm 2000$ at zero abs. at const. vol. The sp. heat of Cl_2 and HCl can be represented by the formulas $1963 + (E_{Cl_2} - 93)/(T - 291)$; $4.963 + E_{HCl}/(T - 291)$, where E_{Cl_2} and E_{HCl} are Einstein functions with $\beta\nu$ equal 902 and 3420, resp. Data on the degree of dissoen. of HCl are consistent with accepted values by other methods.

F. R. BICHOWSKY

The specific heat of hydrogen. G. H. DIEKE. *Physica* 5, 412–9(1925).—From the band spectrum of mol. H the occurrence of half quantum nos. in mol. rotation has become apparent. The author, therefore, recalcd. the Ehrenfest (*C. A.* 7, 3069) and Reiche (*C. A.* 14, 2879) theory. The results shown in curves do not give conclusive evidence in favor of any of several possible auxiliary suppositions; at high temps. discrepancies are notable. A tabulation of values for the moment of inertia is given; the work of Schrödinger (*C. A.* 19, 1089) and of Kemble and van Vleck (*C. A.* 17, 3639) is discussed.

B. J. C. VAN DER HOEVEN

Determination of the equivalent humidity in a differential calorimeter by means of thermoelectric piles. A. K. NOYONS. *Compt. rend. soc. biol.* 93, 845–9(1925).

S. MORGULIS

The heat of adsorption of gases by coal and charcoal. A. G. R. WHITEHOUSE. *J. Soc. Chem. Ind.* 45, 13–20T(1926).—The heats of adsorption of CO_2 , SO_2 , CH_4 , O_2 , N_2 and CO by 4 samples of English coals and 1 sample of an activated charcoal have been measured at 0° . The heat evolved per cc. of gas adsorbed progressively decreases as addnl. gas is adsorbed. In this respect the charcoal and the different types of coal were similar. The data obtained for the heat evolved (cals. per cc. gas adsorbed) are CO_2 , 0.346–0.255; SO_2 , 0.627–0.359; CH_4 , 0.245–0.199; O_2 , 0.19–0.17; N_2 , 0.22–

0.17; and CO, 0.198–0.188. The rates of adsorption for the coals and the charcoal are different. The gases studied were adsorbed much more rapidly by the charcoal than by the coals, the difference being most marked for CH_4 and N_2 . N_2 is adsorbed slightly more rapidly than CH_4 by coal, but in smaller amts., while SO_2 and CO_2 are adsorbed at a much greater rate and in larger amts. than CH_4 . The slow rate of adsorption in the case of coal may be accounted for by there being a small no. of large (distributory) capillaries, or, by obstructions of these capillaries by certain of the constituents of the coal. The simple exponential equation, $h = mx^n$, connecting the total heat evolved per g. of adsorbent with the total volume of gas adsorbed per g. of adsorbent, has been found to be valid throughout the range covered by the expts. However, heats of adsorption cannot be completely expressed by any simple exponential equation.

J. H. PERRY

Micro-determination of melting points, and transition points. D. VORLÄNDER AND ULRICH HABERLAND. *Ber.* 55B, 2652–6(1925).—An elec. heated microscope stage, designed by Gutmann for qual. observations and made by Zeiss, has been used for the quant. detn. of m. p. and transition points. The technic and advantages of the method are described. The temp. is not measured directly, but an amp.-temp., or a watt-temp. calibration curve is used. The watt-temp. curve is preferable because of the inconstancy of the resistance of the Pt heating element of the stage. A list is given of org. compds. m. 91–234° which are suitable for calibrating the stage. A comparison is made of the transition points of several monotropic and enantiotropic cryst. org. liquids, and of anhydrous AgClO_4 (rhombic and regular cryst. phases) as detd. microscopically and thermometrically.

R. H. LOMBARD

The ratio: internal latent heat of vaporization–molecular superficial energy, in connection with the law of corresponding states. J. J. VAN LAAR. *Verslag Akad. Wetenschappen Amsterdam* 34, 803–15; *Proc. Acad. Sci. Amsterdam* 28, 781(1925).

G. CALINGAERT

Temperature coefficient of the dielectric constant of liquid and solid hydrogen. W. WERNER AND W. H. KEESOM. *Verslag Akad. Wetenschappen Amsterdam* 34, 745–51(1925).—The dielec. const. ϵ of H_2 is measured by an improvement of the Wolkfe and Kammerlingh Onnes method (*C. A.* 19, 758). At the b. p., 20.36° K., $\epsilon_B = 1.2311 \pm 0.0002$. The ϵ curve between the b. p. and f. p. is linear. In the neighborhood of the f. p. ϵ (liq.) = 1.2533, ϵ (sol.) = 1.206–1.209. For solid H_2 , ϵ drops with the temp.

G. CALINGAERT

Isotherms of diatomic gases and their binary mixtures. XXXIII. Isotherms of oxygen at temperatures ranging from -40° to -150° and pressures from 3 to 9 atmospheres. G. P. NIJHOFF AND W. H. KEESOM. *Verslag Akad. Wetenschappen Amsterdam* 34, 905–12(1925).—Exptl. detn. of the normal vol. of O_2 , by an improvement of the Kammerlingh Onnes method (*ibid.* 7, 176(1898)).

G. CALINGAERT

The analog of Clapeyron's law for the vaporization of electrons. J. DROST. *Verslag Akad. Wetenschappen Amsterdam* 34, 1016–20(1925).—The formula $d \ln N_0 / dT = \epsilon / KT^2$ is derived for the vaporization of electrons, in which N_0 = concn. of "electron gas" and ϵ = energy of vaporization of the electrons.

G. CALINGAERT

The absolute value of the entropy of real gases. III. VLADIMIR NJEGOVAN. *Z. Elektrochem.* 31, 631–3(1925); cf. *C. A.* 19, 1651.—The so-called integration const. in the expression for the entropy of a gas is displayed for real gases as a function of the internal energy. The true const. of integration must be zero in accord with the third law.

A. P.-C

Conductance of solutions of alkali metals in liquid ammonia and in methylamine. G. E. GIBSON AND T. E. PHIPPS. *J. Am. Chem. Soc.* 48, 312–26(1926).—The conductances of solns. of Na and K in NH_3 and of Cs, CsI and K in methylamine have been detd. at temps. below -33° . The results in NH_3 are in agreement with those of Kraus (*C. A.* 15, 1849). The temp. coeff. of conductance, $d \log R / dT$ is independent of temp., that is, the conductance is an exponential function of temp. at all dilns. The metals are less ionized in methylamine than in NH_3 . The min. in the mol. cond. occurs at a lower concn. in NH_3 than in methylamine. The results are in accord with the view

that the neg. carriers are electrons largely combined with solvent molcs., the degree of solvation diminishing as the temp. rises.

Electrolysis of oxides dissolved in fused boric acid or borates. JAMES M. BELL ANDRIEUX. *Compt. rend.* 182, 126-7(1926).—By electrolysis of borax at about 800° in a carbon crucible with a cathode of Fe which can be cooled internally, a metallic lump can be obtained, which consists of pure Na inside, then a layer of Na and B and of pure B, covered by a coat of solid electrolyte. Addn. of slightly sol. oxides, e. g., Al_2O_3 or BeO , almost entirely prevents reduction of the electrolyte by Na. High temps. favor the reduction and decrease the production of Na and increase that of B. Oxides of metals less electropositive produce the free metals.

The diffusion gas-electrode. ALFRED SCHMID. Enke, Stuttgart, *Separate* 1923, 5-57.—S. studies the polarization of a H_2 -halogen chain, with the ultimate purpose of forming a cell to convert combustion energy directly into elec. energy. The sorption of gases by noble metals is (1) by absorption and capillary diffusion, which consists of a mech. penetration of the gas into the pores of the metal—no activation, but a satn. process—or (2) by a true soln.—an activation. Between cryst. Pt and Pt black all transition stages were produced by electrodeposition. C electrodes may be covered with amorphous, shiny metallic Pt and these are characteristic of (1). A hollow arc-lamp carbon is boiled with NaOH several hrs., polished with fine sand and rubbed clean with alc. It is rotated at 100 r. p. m. in a platinizing soln. ($PtCl_4$, 1/3%; citric acid N/15; H_2SO_4 , M/15) and a current of 1-2 milliamp. per $cm.^2$ is passed through it for 150 min. (about 0.05 g. Pt deposited). Water (70°) is drawn through the electrode by suction to wash it. The penetration of the gas through the metal is a result of the porosity of the latter and properties such as sorption and passivity of Pt are discussed from this viewpoint. Similar halogen diffusion electrodes were built. The p. d. of the chain $H_2 | N HCl | Cl_2$ at 20° and 760 mm. is 1.360 v.; that of $H_2 | N HCl | N KBr | Br_2$ is 1.080 v.; and that of $H_2 | N HCl | N KI | 0.5 N I_2$ is 0.5400 v. dE/dt for t between 20° and 40° is —0.00100 for these cells. The heat of neutralization of HCl and NaOH as calcd. from the Gibbs-Helmholtz equation agrees within 5% of the accepted value of 13.7 cal. The best delivery cited of the H_2 electrode was 230 milliamps. at 0.43 v. (original p. d. was 1.080 v. at O current). Up to this current polarization did not set in.

The effect of the electrode material on oxidation potentials. J. A. V. BUTLER, W. E. HUGH AND D. H. HEY. *Trans. Faraday Soc.* 1926 (advance proof), Jan. 18.—The independence of oxidation potentials of the electrode material when this takes no appreciable part in the cell reaction is confirmed. Electrodes of Pt, Pd, Ir, Os, Au, Rh and Ru give the same oxidation p. d. (0.1905 ± 0.0001 v.) for the cell $Hg | Hg_2Cl_2, KCl N | K_3Fe(CN)_6, 0.005 N, K_4Fe(CN)_6, 0.005 N, KCl N | M$. Electrodes of Mo, W, Ni, Ag and Hg do not give const. p. ds. In a cell of lower oxidation p. d. ($CuCl, CuCl_2$ mixt. in aq. NH_3) the potential is the same (within 0.0001 v.) for electrodes of Pd, Ir, Au, Os, Rh, Ru, Ag, Ni and Hg, whereas it is not const. for electrodes of Mo, W, Ta, As, Sb. Se (metallic) and graphite give const. p. ds. differing from Pt by 0.3 and 0.6 milliv., resp.

The transference numbers of sodium and hydrogen in mixed chloride solution. MILLICENT TAYLOR. *J. Am. Chem. Soc.* 48, 599-603(1926).—Transference nos. have been detd. in a soln. of NaCl contg. HCl. Contrary to the results of Schneider and Braley (*C. A.* 17, 2218), T. finds that only simple ions and no complex ions are present in this type of soln.

The electrostatic virial of strong electrolytes. E. Q. ADAMS. *J. Am. Chem. Soc.* 48, 621-6(1926).—A virial term for the energy of strong electrolytes in aq. solns. derived from the dielec. const. of H_2O should be denoted by ΔF (free energy at const. pressure) and not by ΔU (total internal energy) since the detn. of the dielec. const. of H_2O involves measurements of the elec. work obtainable by discharging at const. pressure a condenser filled with H_2O . Only if the dielec. const. is independent of temp. are the 2 thermodynamic functions, ΔF and ΔU , equal. The conclusions arrived at by Milner, Debye and Hückel and by Noyes are discussed in light of this fact. The osmotic pressure can be calcd. from ΔA and from ΔF , without a knowledge of the temp. coeff. of the dielec. const. of H_2O .

The change in potential of the hydrogen electrode with pressure. G. TAMMANN AND H. DICKMANN. *Z. anorg. allgem. Chem.* 150, 129-46(1926).—The change in potential of a 0.1 N H electrode has been detd. for pressures up to 3000 kg./ $cm.^2$. The potentials measured nearly coincide with the potentials calcd. on the assumption that H is a perfect gas, while allowance for the deviation from the perfect-gas law leads to calcd. values higher than those obtained by expt. In the empirical formula derived

for the change with pressure in potentials of the H electrode, the internal pressure brought about by dissolved neutral salts may be substituted for the external pressure. The agreement between the values thus calcd. for the effect of dissolved neutral salts on the potential and the values experimentally detd. are quite satisfactory. From the viscosity of the salt solns. it is possible to study the variations in activity of the H ions with internal or external pressure.

PER K. FRÖLICH

Remarks on the diamagnetism of bismuth. P. EHRENFEST. (*Physica* 5, 388-41 (1925).—The value of the diamagnetic susceptibility $\chi_{\text{Bi}} = 292$ is abnormally high. Pauli's relation (*C. A.* 15, 2773) $\chi = 2.85 \times 10^{10} \sum r_i^2 / \langle r^2 \rangle$ ($\langle r^2 \rangle$ is the mean square of the distance of one electron of the atom of the nucleus, $i = 1, 2, \dots, Z$ for Z the at. no.) leads to radii of the outer electron orbits (8 A. U.) larger than the distance between Bi and Bi in the crystal lattice (3.11 or 3.47 A. U.). E., therefore, concludes that some electrons in solid Bi have orbits, crystallographically defined, that enclose several at. nuclei. This is in agreement with (1) the strong change in susceptibility of Bi at the m. p. (tenfold decrease, also occurring for Sb and Ga); (2) the increase in elec. cond. at the m. p. for these three metals; (3) the anisotropy of χ in Bi crystals (100:70 parallel and perpendicular to principal axis). Between these orbits a complete coupling must exist, which prevents them from having a residual magnetic moment.

B. J. C. v. D. H.

The influence of a magnetic field on the resistance of superconductors. W. J. DE HAAS, G. J. SIZOO AND H. KAMERLINGH ONNES. (*Physica* 5, 447-52 (1925).—Preliminary report. Hg wires, of which the resistance was detd. in a magnetic field (potentiometric method) at temps. below its leap-point (4.2° abs.) showed a renewed actual resistance, the max. of which falls on a continuous curve with the ordinary resistance (without magnetic field) above the leap-point. The difference in character of superconductive and non-superconductive substances can be made to disappear by a sufficiently strong magnetic field. The resistance/ H isotherm at 3.79° and 3.96° abs. shows considerable hysteresis effect; going down from high H values, $W/H_{4.1}$ (W is resistance) decreases discontinuously in some 2 or 3 steps to zero; on again increasing H , $W/W_{4.2}$ has a lag of about 10 gaussers and then begins slowly but continuously to rise in an S curve up to the above-mentioned max. value. It is possible that the S curve consists of a great no. of small steps (the same effect was found for Sn). The max. is reached for about 40-80 gaussers, increase of the field strength to 300 gaussers makes no difference, neither does variation of the current d . (1-28 milliamps.). The Hg wires used were 10-15 mm. long, 0.02-0.05 mm. diameter, placed in a 16.5-cm. solenoid. The discontinuities and hysteresis may be due to sudden supercond. of the individual Hg crystals.

B. J. C. VAN DER HOEFEN

The constant paramagnetism of solutions. M. LE PAULE COLLET. (*Compt. rend.* 181, 1057-8 (1925).—In previous work C. and Weiss found the susceptibility of Cr in soln. to be 63.3×10^{-6} (cf. *C. A.* 18, 3533). This value was const. in the temp. range 14° to 50° for solns. and for the solid from 12° to 90°. They now find that the susceptibility of Co is also independent of temp. with the value 14.4×10^{-6} .

W. W. STIFLER

An experiment on the orientation of paramagnetic molecules. P. DERVE AND A. HUBER. (*Physica* 5, 377-81 (1925).—An effort was made to find out whether in a paramagnetic gas (NO) the mols. become oriented under the influence of a magnetic field, thus causing the appearance of an elec. moment m_s , detectable by a quadrant electrometer, of the order $m_s = \mu_s \mu_m H / 3kT$ (μ_s 's are mol. moments, H is magnetic field). No charging effect was noticed more than $1/1000$ of that expected (μ_s for NO estd. 0.6×10^{-19} e. s. u.; $\mu_m = 1.7 \times 10^{-20}$ e. m. u.). This shows that orientation is very unlikely and (unless μ_m is perpendicular to μ_s or $\mu_s = 0$) confirms the view of Ehrenfest (*Comm. Leiden Suppl.* 44b, 55) rather than that of Langevin.

B. J. C. VAN DER HOEFEN

Magnetic properties of single iron crystals. WALTHER GERLACH. (*Physik Z.* 26, 914-5 (1925).—A sample consisting of a single crystal of electrolytic Fe showed practically no hysteresis loss nor remanence. The I - H curve is given for it and for a specimen of similar dimensions of ordinary electrolytic Fe.

W. W. STIFLER

The magnetochemistry of closed chains. P. PASCAL. (*Compt. rend.* 181, 656-8 (1925); cf. *C. A.* 19, 2773).—The mol. magnetic susceptibilities computed by the additive principle for derivs. of 3, 4, 5 and 6 C atoms rings are compared with expt. There is a difference Δ between the exptl. and observed values, and it is shown that Δ is quant. proportional to the amt. of deformation of the C bonds from their usual positions at the tetrahedron corners, thus agreeing with the Baeyer strain theory.

S. K. ALLISON

Experiments on the electrical symmetry of nickel molecules. ALBERT PERRIER

AND CH.-E. BOREL. *Arch. sci. phys. nat.* **7**, 289-98(1925); cf. *C. A.* **18**, 616.—It has been shown previously for Fe that an elec. current, or the field which maintains it, excites or modifies the magnetization of the Fe through which it travels, in a manner longitudinal with respect to the elec. field and in the reverse sense. This would indicate that the Fe mols. possessed an elec. moment of opposite sense to their magnetic moment. This phenomenon is now studied in Ni, by more sensitive methods, which are described. The behavior of Ni at ordinary temp. is so complex that it was necessary to work at high temp. (Curie point). The results obtained at high temp. will be presented in a subsequent paper.

Remarks on the quantum mechanics of Heisenberg. H. A. KRAMERS. *Physica* 5, 369-76(1925).—A phys. interpretation of some results of the Heisenberg (C. A. 20, 1026) theory. An electron bound to an atom is in its behavior towards an oscillating elec. field of high frequency asymptotically identical to a classical vibrator. B. J. C. v. D. H.

Regularities in the action of electromagnetic waves—nuclear decomposition. ERNST BRUMMER. *Z. Elektrochem.* 32, 7-13(1926).—General discussion, leading to the rule that with decreasing wave length the point of action approaches the at. nucleus. The wave length necessary for dissociation of N is calcd. from the energy of the α -particles producing this effect, and from the energy of the packing effect, agreeing on approx 10^{-11} cm. B. H. CARROLL.

A possibility of deriving the characteristic properties of nucleus and electron from the "metric" electromagnetic field. H. REISSNER. *Physik. Z.* 26, 925-32(1925).—A highly mathematical paper in which the problem is discussed both from the classical and from the quantum viewpoints. W. W. STIFLER.

A supposed relativity method of determining the size of a gravitating particle. H. T. H. PIAGGIO AND J. CRITCHLOW. *Phil. Mag.* [7], 1, 67-71(1926).—A singularity in Schwarzschild's soln. of Einstein's equations which has been widely interpreted as indicating a definite size for a gravitating particle, is shown to be merely a mathematical property of a transformation of coordinates, without any phys. significance. S. C. L.

Models of electron structure, quantum action, and the gravitational field. W. M. THORNTON. *Phil. Mag.* [7], 1, 13-31(1926).—Models are presented of the assumed structure of electrons and of protons as an aid in visualizing mechanically their various phenomena and behavior such as the attraction of opposite charges, the linkage in a H atom, the absence of magnetic field of a single orbit, reaction of radiation on atomic field, mechanism of quantum action, vibrations with zero energy, mass of protons and electrons, cohesion and gravitation, chem. combination and gravitational force, existence of electrons in the nucleus, radioactivity and the He atom, generation of elec. charges,

Faraday's Law of electromagnetic induction, a possible magneton or unit of magnetism, and the diameters of vortex filaments. S. C. L.

Are the magnetic moments of atomic nuclei detectable by α -ray deflection? WALTER WESSEL. *Ann. Physik* 78, 757-85(1925).—A math. discussion of how a parallel, small bundle of α -rays will be deflected by a thin layer of at. nuclei when these nuclei possess a magnetic moment. MARIE FARNSWORTH

Researches on mesothorium. II. D. K. YOVANOVITCH. *J. chim. phys.* 23, 1-37(1926).—The method of purifying the Ms-Th II is to dissolve the mixts. of salts and ppt. the Ra, Ba, etc., with concd. HCl. Rare earth salts are then added and pptd. with NH_4OH which carries down the Ms-Th II. For purification this is redissolved in HCl and repptd. The Rd-Th is removed by pptg. a trace of $\text{Th}(\text{NO}_3)_4$ with H_2O_2 . The active deposit of Ra is pptd. with H_2S after adding a trace of $\text{Bi}(\text{NO}_3)_3$ and $\text{Pb}(\text{NO}_3)_2$. The Ms-Th II and rare earths are finally pptd. as oxalates. This very pure sample gives $T = 6.18$ hrs. By fractionation of the rare earths of the Ce group, the Ms-Th II is concd. in the more basic fraction (La). A complete magnetic spectrum of the β -rays of 43 lines is given. The velocity of the most rapid ray is 0.9983 that of light and the velocity of the slowest 0.36. A possible interpretation of the very rapid rays is given. MARIE FARNSWORTH

The life period of the metastable states of neon and mercury. H. B. DORGELO. *Physica* 5, 429-42(1925); cf. *C. A.* 20, 335.—The life period of $\text{Ne } s_3$ at 18° is $1/240$ sec., of s_3 $1/2000$ sec. The s_3 period changes considerably with temp. of the absorption tube; at 171° it is $1/1650$ sec., at -196° $1/10$ sec. For Hg the $2p_1$ and $2p_2$ conditions are metastable; their life period, as measured from 5461 and 4046 lines, was strongly dependent upon the presence of impurities. The max. period found for $2p_1$ was $1/200$ sec.; for $2p_2$ it is longer. Traces of H (second-order collisions) completely destroy the metastable possibilities [contrary to results of Marshall (*C. A.* 19, 603); cf. Eckardt, *C. A.* 19, 2164]. At higher temps. (200°) λ 4358 is strongly adsorbed; it remains visible at 90° for 8×10^{-6} sec. after excitation (measured with high-frequency circuit). The life period of neon s_3 is probably largely detd. by second-order collisions; the difference in energy between s_3 and s_4 of only 0.05 v., i. e., of the order of the heat energy of the atoms, explains the temp. influence upon it. Similar explanations hold for the other metastable atoms. Destruction by diffusion to the walls plays only a minor role at ordinary temps. B. J. C. VAN DER HOEVEN

Atomic weight of isotopic lead in cleveite from Aust-Agden, Norway. ELLEN GLEDITSCH, MME. DORENFELDT HOLTAN AND O. W. BERG. *J. chim. phys.* 22, 253-63 (1925).—The at. wt. of Pb in a sample of very pure cleveite, contg. 78.7% U_3O_8 , 0.95% ThO_2 , 11.41% PbO , 3.00% C_2O_3 , and small amts. of SiO_2 , Fe_2O_3 , Al_2O_3 , CaO , MgO and rare earths, from Aust-Agden, Norway, was detd. by 2 methods. (1) Direct detn., weighing PbCl_2 followed by conversion to PbSO_4 yielded 206.17 for Pb in cleveite and 207.22 for ordinary Pb. (2) An indirect method involving the comparison of the ds. of satd. solns. of the isotopic and ordinary $\text{Pb}(\text{NO}_3)_2$ yielded $d_4^{19.94} = 1.417941 \pm 0.000009$ and 1.419475 ± 0.000025 , resp. 1 l. of the satd. soln. (19.94°) contains 501.109 g. $\text{Pb}(\text{NO}_3)_2 = 1.522067$ g. mols. (detd. on common $\text{Pb}(\text{NO}_3)_2$; mol. soly. is the same for all isotopes of a given at. no.). If the at. wt. of common Pb is taken = 207.18, this detn. yields 206.17 ± 0.02 for the at. wt. of Pb from this sample of cleveite. F. C. KRACK

The δ -rays produced by α -particles in different gases. J. CHADWICK AND K. G. EMMELÉUS. *Phil. Mag.* [7], 1, 1-12(1926).—The production of δ -rays by α -particles has been studied by photographing the tracks produced in a Wilson expansion chamber. The objects were to det. (1) the energy and direction of emission; (2) the dependence of the production on the velocity of the α -particle; and (3) the dependence on the gaseous medium. The tracks were studied in H_2 , He, air and A. The δ -rays appear to result from a collision of an α -particle with an electron in the atoms through which it passes. It is assumed that the α -particle and electron behave as point-charges and that the inverse-square law of force is followed. The ranges of the δ -rays in the different gases have the same ratio to the air-range as for α -particles in the same gases. The max. velocity that can be given to the electron is twice that of the impinging α -particle. S. C. LIND

Action of radon on mixtures containing ammonia and an oxide of carbon. K. C. BAILEY. *Sci. Proc. Roy. Dublin Soc.* 18, 165-8(1926).—The action of radon on mixts. of CO with NH_3 and CO_2 with NH_3 was investigated. $\text{CO} + \text{NH}_3 = \text{H}_2\text{O} + \text{HCN}$ (*Ann.* 38, 62(1841)) is considered the normal reaction. $\text{CO} + \text{NH}_3 = \text{H}_2 + \text{HOCN}$ (*J. Chem. Soc.* 87, 433(1905)) was obtained by Jackson and Northall-Laurie. Radon

causes the 2nd reaction to take place. A catalyst is necessary for the first reaction. The reaction with CO_2 produced cyanate and urea. Quantitatively the expts. with CO_2 were unsatisfactory. B. expects to repeat. Similar expts. with ultra-violet light instead of radon are in progress. L. D. R.

The radioactive phosphorus-arsenic-iron-sulfate springs of the diadochite caves (fairy grottos) of Saalfeld in Thüringen. ANON. *Gas u. Wasserfach* 69, 28-9 (1926). The mineral content of these springs is very high, one showing (g/l.) As_2O_5 4, P_2O_5 80, H_2SO_4 110, Fe 130, Al 20, Mn 0.2, Mo 0.15, Cu 0.1, its d. being 1.31, its residual radioactivity being 30 Mache-units/l. Analyses of the gas arising from the springs showed 91.5% N_2 , 6.8% CO_2 , 1.7% noble gases. Analyses of solid deposits, and of other springs similar to the above, are given. W. B. PLUMMER

The mobility of gaseous ions in HCl gas and HCl air mixtures. L. B. LOEB. *Proc. Nat. Acad. Sci.* 12, 35-41 (1925); cf. *C. A.* 19, 10, 1814.—Mobility measurement made in pure dry HCl gas given the av. mobility for the positive ion at 20° and 760 mm. pressure as 0.65 cm./sec. per volt/cm. and for the negative ion as 0.56 cm./sec. per volt/cm. This measurement of a negative mobility, definitely less than a positive mobility constitutes the first exception to a general rule previously assumed from observation which indicated that the neg. ion has a mobility either equal to or greater than the pos. ion, but not less. The inverse-pressure law of mobilities holds for both positive and negative ions down to 16.3 mm. pressure. The const. of attachment of electrons to HCl mols. to form negative ions was nearly as low as that for Cl_2 gas. Measurements of mobilities in mixts. of air and HCl showed unmistakable signs of a cluster ion formation in this gas, the mobilities being lowered by marked amts. for fractions of a percent of HCl gas. G. L. CLARK

The mobility of gas ions in HCl mixtures and the nature of the ion. L. B. LOEB. *Proc. Nat. Acad. Sci.* 12, 42-8 (1926); cf. *C. A.* 19, 1814.—The preceding results indicate the ability of the ion to gather around it a higher concn. of HCl than is present in the rest of the gas; i. e., a definite labile cluster formation. Upon the basis that air and HCl mols are attracted to an ion with forces varying inversely as the 5th power, calcns. show that in a mixt. of 0.2% HCl and 99.8% air a cluster on the av. would consist of 1 HCl and 1 air mol. The mobility equations previously derived by L. do not include the effect of increased concn. of active mols. G. L. CLARK

Electron conduction in rarefied gases. A. D. FOKKER. *Physica* 5, 334-41 (1925). In a homogeneous elec. field, taking the atoms as perfectly elastic immovable spheres and the electron density low enough, so as not to disturb the field, F. finds for the flow of electrons: $i = \frac{1}{3} [(X/\sqrt{2Xx})\rho - \sqrt{2Xx}(d\rho/dx)]$; l is mean free path, X the acceleration in the field, ρ the electron density. The density is not influenced by the field strength and is for a homogeneous field $\rho = B\sqrt{x} \log(a/x)$, in which B and a are integration consts. The current is proportional to the sq. root of the elec. force. B. J. C. VAN DER HOEVEN

Ionization equilibrium in a stationary radiation field. J. WOLTJER, JR. *Physica* 5, 406-11 (1925).—Saha and Swe (*C. A.* 19, 1811) have given a relation for the degree of ionization of a gas as depending upon the reaction equil. of neutral atoms, ions, electrons and irradiating light impulses. Following a different method W. arrives at a similar result (cf. *C. A.* 20, 143). His equation becomes identical with the one of S. and S. on assuming that only light of one frequency can ionize. B. J. C. v. d. H.

The part taken by different energy levels in the emission of thermoelectrons. H. J. VAN LEEUWEN. *Physica* 5, 347-50 (1925).—On the basis of the classical statistical theory it is shown for the electron equil. of a heated body with multiple energy levels that the no. of free electrons is proportional to $e^{-\epsilon_1/kT}$ in which ϵ_1 is the energy of the first step (outer orbit). This result is in agreement with the expts. but contrary to a result of Richardson (*C. A.* 18, 3536). The assumption is used that a limited no. of places are available for electrons in each level and that these numbers are of the same order of magnitude for the different levels. B. J. C. VAN DER HOEVEN

Zeeman effect of molybdenum. E. WILHELMY. *Naturwissenschaften* 13, 49-50 (1926).—Preliminary report in which 39 wave lengths are tabulated. The results are in agreement with and complete data of Catalan (*C. A.* 18, 1427) and of Kiess (*C. A.* 17, 3453). B. J. C. VAN DER HOEVEN

Intensity measurements of Stark effect. T. TAKAMINE AND SVEN WERNER. *Naturwissenschaften* 13, 47-8 (1926).—Hansen, T. and W. have given measurements (*C. A.* 18, 3541) on the Stark effect in Hg; in the present paper a preliminary account is given of a continuation of this work. It is shown that the intensity of both $2p-4p$ (parhelium) and $2p-4p$ (orthohelium) in the Stark spectrum is proportional to the

square of the elec. field intensity (all measurements were done on the light component parallel to the field). Another theoretical conclusion, that the intensity of a new line is *inversely* proportional to the difference between influenced term and nearest hydrogen term, was also confirmed from the intensity ratios $J_{2P-4P}/J_{2P-4D} = 0.025$, $J_{2P-4P}/J_{2P-4D} = 0.0015$, $J_{2P-4P}/J_{2P-4D} = 0.4$; $J_{2P-4P}/J_{2P-4D} = 0.3$ (all for $E = 13,200$ v./cm.). The intensity of new lines increases for higher members of the same series $J_{2P-mP}/J_{2P-md} = 0.025, 0.4$ and 1.0 for $m = 4, 5$ and 6 , resp.; little polarization for $m = 4$, strong for $m = 6$ was found.

B. J. C. VAN DER HOEVEN

The low-voltage arc in mercury vapor. RICHARD RUDY. *J. Franklin Inst.* **201**, 248-50(1926).—Because of the existence of reverse fields as high as 10 v. in the presence of a it is possible to get the whole v.-amp. curve below the crit. 5 v. F. O. A.

The relation between temperature and minimum sparking potential. E. F. BURTON. *Phil. Mag.* [7], **1**, 219-24(1926).—The min. sparking potentials in air between solid brass cylinders was detd. over a range of temps. from -190° to $+200^{\circ}$. The min potential dropped from 505 to 346 v. while the density of the air relative to 0° changed from 3.37 to 0.58. S. C. L.

Langevin's theory of ionic mobility. H. R. HASSÉ. *Phil. Mag.* [7], **1**, 139-59(1926).—An exhaustive review and recalcn. of the Langevin equation (*Ann. chim. phys.* [8], **5**, 245(1905)) is given with crit. discussion of other methods of detg. and calcg. ionic mobility. Comparison is made between the predicted and exptl. mobilities. While agreement is fair for most gases, the disagreement is so great for H_2 and He as to suggest that the agreement for other gases may be accidental. The paper is preliminary in character and serves chiefly to point out the difficulties and unsatisfactory state of measuring and especially of interpreting ionic mobilities. S. C. LIND

The absorption of hydrogen in potassium vapor arcs. R. D. RUSK. *Phil. Mag.* [7], **1**, 97-109(1926).—When a low-voltage arc is passed through a mixt. of He and K vapor at temps. of 40° to 180° beginning with initial pressure of about 1 mm. or less, a reduction in pressure results owing to the formation of KH. The reaction is more rapid the higher the temp. The reaction is attributed to some active form of H not formed at less than 16 v. K ions do not unite with mol. H_2 since absorption should then occur at 4.3 v., the ionization potential of K. R. gives reasons for believing that the active form of H is atomic and extends this view to the thermal union, calcg. a dissociation of H_2 at 300° and 760 mm. of 1.75×10^{-11} from Nernst's reaction isobar, while the rate of reaction would give a value about 16 times higher, assuming combination on first collision. S. C. LIND

The intensities of the Zeeman components of multiple lines. W. C. VAN GEEL. *Physik* **33**, 836-42(1925).—The rule for the intensities of the Zeeman components of multiple lines proposed by Hönl is found to agree well with expt. for an octet system (Mn), a septet system (Cr) and a quintet system (Cr). H. C. UREY

The screening doublets of the Bowen-Millikan ultra-violet spectra. ALBRECHT UNSÖLD. *Z. Physik* **33**, 843-48(1925).—The energy of the valence electron is expanded in terms of s/Z , s being the screening const. and Z the at. no. and the quantum conditions applied. The calcd. values for $\Delta\sqrt{\nu}$ agree well with those observed for S(VI), P(V), Si(IV), Al(III) and Mg(II). H. C. UREY

Total reflection and the variation of the index of refraction of X-rays in the vicinity of an absorption discontinuity of the mirror. M. DE BROGLIE AND J. THIBAUD. *Compt. rend.* **181**, 1034-5(1925). GEORGE L. CLARK

The symmetry of X-ray interferences. P. P. EWALD. *Physica* **5**, 363-9(1925). (in German).—Equal reflecting power of any crystal plane from both sides (centrosymmetry) is essential for symmetry of the interference pattern. On the basis of the Laue-Bragg theory this equality fails if the different atoms of one plane produce waves with differences in phase relative to the impinging wave. The dynamic theory of reflection, which includes interaction of primary and secondary radiation, always leads to the centrosymmetrical condition and thus proves the general validity of the Friedel rule (C. A. **8**, 1911). B. J. C. VAN DER HOEVEN

Changes in the cathode of the arc discharge. R. SEELIGER. *Physik. Z.* **27**, 22-41(1926).—A crit. discussion and summary of work in this field, with emphasis on the following topics: (1) different forms and definition of the arc discharge; (2) qual. theory of the cathode field; (3) current distribution in the cathode; (4) the burning patch; (5) disadvantages of the thermal arc theory. H. R. MOORE

Origin of penetrating radiation in the atmosphere. FRANZ BĚHOUNEK. *Physik. Z.* **27**, 8-10(1926).—The ionization in a modified Kolhörster app. (*Science Abstracts* **25A**, 1388) is plotted as a function of the thickness of the Pb walls. The currents are

const. as soon as the wall attains a thickness of 10 cm. and this is ascribed to a residual activity of the app. Direct measurements of the absorption coeffs. of γ -rays from Ra C confirm the formula of Ahmad and Stoner (*C. A.* **18**, 3312). The conclusion is reached that highly penetrating radiation is not of cosmic origin, but is due to radiation of radioactive products (cf. Thibaud, *C. A.* **18**, 3001).

H. R. MOORE

Theory of the continuous X-ray spectrum. M. SANDOVAL VALLARTA. *J. Math. Physics* **5**, 1-7(1925).—A quantum theory of the continuous X-ray spectrum is based upon the following assumptions: (1) The continuous spectrum is due solely to the stoppage of electrons at the anticathode; (2) radiation from an electron due to a fortuitous loss of kinetic energy takes place in accord with Bohr's frequency relation; (3) conservation of energy and momentum hold for the system consisting of electron, anticathode atom and light quantum. Making use of the principle of variation of mass with velocity for both atoms and electrons and the law of inertia of energy for the emitted light quantum, V. obtains an expression for the high frequency limit of the spectrum, ν_0 , which differs slightly from that given by the Einstein-Planck formula $T_1 = h\nu_0$, where T_1 is the kinetic energy of the electron. The difference between the two expressions would not be detectable for anticathode elements heavier than Al and for voltages above 1 kv.

R. J. HAVIGHURST

The soft X-ray absorption limits of certain elements. URSULA ANDREWES, ANN C. DAVIES AND FRANK HORTON. *Proc. Roy. Soc. (London)* **110A**, 64-90(1926).—By a photoelec. method, voltages corresponding to the crit. values of the electron energy associated with some of the longer wave-length absorption stages of the 7 successive elements Cr, Mn, Fe, Co, Ni, Cu, Zn, have been measured. Comparison of measured absorption limits and emission lines shows that the generally accepted value of an absorption limit, obtained by spectroscopic methods, corresponds not to ionization of the atom by the detachment from it of an electron in the sub-group concerned, but to the transportation of the electron from the sub-group to the periphery of the atom, i. e. to the levels of the most loosely bound electrons. For the more deeply seated levels within the atom, the quantity of energy required to move an electron to the periphery differs very little from that required to effect its complete detachment from the atom. The values obtained in this investigation are associated with absorption of energy by electrons in the M_I and $M_{II,III}$ sub-groups and their transference to virtual orbits outside the normally occupied region of the atom, and not to actual ionization of the atom.

R. J. HAVIGHURST

The scattering coefficient for hard X-rays. W. BOTHE. *Z. Physik* **34**, 819(1925)

The elementary process of the scattering of light by an electron may be considered as follows. The electron, initially at rest, absorbs classically and stores up the energy in some non-classical manner while it is being accelerated by the light pressure. The mass of the stored up energy is to be added to that of the electron in computing the acceleration. When it has reached the "effective velocity" $\bar{\beta}$ it then radiates this energy at the frequency which would appear if light were scattered classically by an electron with the velocity $\bar{\beta}$. It is shown that this conception leads to the same formula for $\bar{\beta}$ in terms of the initial frequency as that previously obtained by A. H. Compton on the pure light-quantum theory. The expression for the ratio of the actual scattering coeff. to the classical does not agree with that obtained by Compton, but appears to fit the exptl. data better.

S. K. ALLISON

The distribution of energy in the continuous X-ray spectrum. M. H. BELL. *Phil. Mag.* [7], **1**, 50-67(1926).—From the cor. exptl. curves given by Dauvillier for a standard Coolidge tube under different const. potentials and currents, an empirical expression of the form $y = a(e^{-bx} - e^{-ax})$ has been found to represent the energy-distribution curve with considerable accuracy. By subdividing the form of a sinusoidal potential wave into a no. of intervals during which an appropriate const. potential is supposed to act, the application of the empirical expression produces an integral distribution curve, which agrees very well with an exptl. curve given by Dauvillier for approx. equal conditions. It is suggested that the energy-distribution curve can, in the same way, be predicted when the forms of the potential and current waves are known. The importance of the knowledge of the energy distribution curve for any type of machine in its application to clinical practice is stressed, and the method of standardizing treatment in terms of the characteristics of the energy distribution curve is suggested as being more precise than the former method of subjecting the patient to a certain no. of erythema doses.

S. C. L.

Observations on the spreading of X-ray pulses. A. JOFFÉ AND N. DOBRONRAVOV. *Z. Physik* **34**, 889(1925).—X-rays were generated in a small tube with an Al target and

a cathode ray beam of photoelectrons from an Al point. Pulses were emitted from this tube at intervals of about 10^{-8} sec. The beam from this tube was allowed to fall on a positively charged Bi particle suspended in a Millikan condenser. At intervals of about 30 min. the loss of an electron by the particle could be observed. Conclusion: The total energy of the pulse is radiated within a solid angle of at most 10^{-6} . S. K. A.

The natural X-ray spectrum of radium B. ERNEST RUTHERFORD AND W. A. WOOSTER. *Proc. Cambridge Phil. Soc.* **28**, 834-7(1925).—An expt. is described which indicates that the natural L spectrum of Ra B corresponds to an element of at. no. 83, thus establishing the fact that the γ -ray emission follows the escape of the disintegration electron from the nucleus. C. C. KIESS

The β -ray spectrum of the natural L-radiation from radium B. D. H. BLACK. *Proc. Cambridge Phil. Soc.* **28**, 832-3(1925).—The analysis of the β -ray spectrum due to the natural L radiation of radium B. *Ibid* 838-43. —These 2 papers describe and tabulate the spectrum of low-energy β -rays of Ra B resulting from the action of L X-rays of the atom on the M, N and O levels of the same atom. Analysis of the spectrum indicates that the L radiation comes from an atom of at. no. 83, supporting the theory that after the ejection of a nuclear β -particle the γ -rays which are emitted act on the various at. levels. The fact that the β -ray spectrum of Th B has been found to be practically the same as that of its isotope Ra B is additional support of this conclusion. C. C. KIESS

Zeeman effect and multiplet structure. ARTHUR BRAMLEY. *J. Frank Inst* **201**, 16(1926). C. C. KIESS

The free-path length of the light stimulation and its disturbances. BALEBAIL DAS-ANNACHARYA. *Ann. Physik* **77**, 597-626(1925).—Measurement of light emission of flying atoms of H-canals rays at varying H-pressures. The results as applied to the disson. theory agree with the conditions in aq. solns. JOHN T. STERN

Intensity of absorption lines in cadmium spectrum. W. KUHN, *Naturwissenschaften* **13**, 48-9(1926).—The method used formerly for Tl vapor (*C. A.* **19**, 3210) was now applied to Cd vapor. For $1S-2P$ ($\lambda = 2288$ A. U.) f was found to be 1.20 ± 0.05 , for $1S-2p_2$ $f = (1.9 \pm 0.2) \cdot 10^{-3}$. It appears (cf. Kronig, *C. A.* **19**, 3060) that the ratio of intensities of intercombination lines for Hg and Cd approx. equals the ratio of the squared distances of the triplet components ($2p_2-2p_0$) for Hg and Cd (6398 and 1713, resp.). From the presence of two 5,1 orbits in normal Cd the $f_{1S-2P} > 1$ is explainable; both electrons take part in the light dispersion. As concluded from correspondence principle the $2P$ term of Cd has a main quantum no. of 5. B. J. C. VAN DER HOEVEN

The fine structure of Balmer lines. G. HANSEN. *Ann. Physik* **78**, 558-600(1925).—Although the structures of H lines have been investigated many times, the results are not certain within $10^{-4}\%$ and the divergences are partly inexplicable because details of the investigations have not been given with sufficient completeness. The earlier measurements are critically discussed and then a full description is given of an investigation of the 5 first members of the Balmer series, a preliminary account of which has already been given (cf. *C. A.* **20**, 543). The source was a long tube cooled in liquid air. Three different Lummer-Gehrcke plates were used for the resolution of the line structures, the performance of the interferometers being tested in an examn. of Cd and He lines. The observations were made photographically and then the interference patterns were drawn by a registering photometer. The evaluation of these curves is described and uncorrected results of the doublet sepn. of 5 lines are given. Two lines, H_{α} and H_{β} , show dissymmetry which suggests a third component for each. The measured sepn. of the doublets are not in good agreement with the Sommerfeld-Kramers theory but this may be accounted for by a Stark effect for time changes and space inhomogeneities in interat. elec. fields. The "half-width" of H_{α} is estd. to be 0.07 A. U., which indicated a temp. of about 230° K. on the assumption of pure Doppler widening. It may be expected that further components may be sepd. if the tube is cooled in liquid H_2 . W. F. MEGGERS

Secondary standards of wave length in the spectra of neon and iron. G. S. MONK. *Astrophys. J.* **62**, 375-86(1925).—In order to det. the consistency and reproducibility of standard wave lengths a series of comparisons was made of the primary standard as emitted by the Michelson tube, by a Cd arc *in vacuo* between Cd-filled C poles, and by a Cd discharge tube of improved form. Within the errors of measurement all 3 sources gave the same wave lengths when compared with Ne lines. Then 110 lines (3445.152 to 6677.991 A. U.) from the standard Fe arc were measured relative to Ne lines. The observed values to the violet of 6000 A. U. agree well with the last observations reported

from the Bur. of Standards while to the red of 6000 A. U. they are systematically about 0.002 A. U. lower than the Bur. of Standards values. W. F. MEGGERS

Effect of the solvent on the ultra-violet spectrum of the solute. H. FISCHER. *Ann. méd. légale* 2, 334-5(1922).—Solvents have a considerable quant. and qual. effect on the spectra of solutes. On the whole, C_6H_{14} and C_6H_{12} give the best spectra, next come H_2O , H_2O and abs. EtOH. EtOH frequently causes considerable change in the spectra, and also H_2O at times. The latter has proved particularly valuable with alkaloids and their salts. A. PAPINEAU-COUTURE

Ultra-violet absorption spectra of narcotine and of its decomposition products. PIERRE STEINER. *Ann. méd. légale* 2, 338-40(1922); cf. *C. A.* 17, 2832.—Narcotine shows a large absorption band with max. for $\lambda = 3115$ A. U. and absorption coeff. $\epsilon = 5000$ approx. at this wave length. As little as 0.07 mg. can be detected in soln. in 1 cc. H_2O . Hydrocotarnine and opianic acid do not show as great adsorption as narcotine and the absorption of the latter is nearer the red end of the spectrum. A. PAPINEAU-COUTURE

The analysis of certain molecular spectra. D. M. DENNISON. *Phil. Mag.* [7], 1, 195-218(1926).—D. extends the consideration of mol. structure as revealed by the positions and fine structure of the infra-red bands to HCl, HBr, HI, CO_2 and NH_3 . The treatment is similar to that employed for CH_4 (*C. A.* 20, 147). S. C. LINE

The effect of solvents on the absorption spectrum of a simple azo dye. W. R. BRODE. *J. Phys. Chem.* 30, 56-69(1926).—A Hilger sector photometer and quartz spectrograph were used to observe the absorption of 30 org. solvents and of solns. in them of the dye benzeneazophenol. The position in the spectrum of the absorption limits of the solvents is shown graphically. In a table are given the observed frequencies and extinction coeffs. of the absorption bands of the dye in each of the solvents. From the observations it is concluded that for this dye, and probably for other simple azo dyes, Kundt's law does not hold which states that the absorption band is displaced redward in the spectrum with increasing index of refraction of the solvent. The absorption band of the dye in mixed solvents appears to be that of the most polar solvent even if this solvent is present in a low percentage. It appears as though the dye is entirely dissolved in the more polar solvent and this soln. is then suspended in the other solvents. C. C. KRESS

The explanation on the correspondence principle of the spontaneous appearance of spectral lines of the type $ms-nd$. GEORG JOOS. *Physik. Z.* 26, 729-30(1925). The line $1s-3d$ of K has been observed under conditions which preclude intermol. electric fields as responsible for its appearance. For such lines there is a change of 2 units in the azimuthal quantum nos. An explanation based on the correspondence principle is offered on the assumption that the angular velocity of the line of apsides is varied depending on the angle which it makes with a fixed direction in the core of the atom. C. C. KRESS

Doublet and triplet separations in optical spectra as evidence whether orbits penetrate into the core. D. R. HARTREE. *Proc. Cambridge Phil. Soc.* 22, 904-18(1925). Comparison of the doublet and triplet seps., of terms in optical spectra is made with Landé's formula to det. whether or not the corresponding orbits penetrate the atom core (*C. A.* 18, 3321). Except for Li-like atoms the evidence presented indicates that all p orbits of doublet and triplet spectra penetrate the core. The evidence for d orbits is not conclusive, though for Cs I and Tl I the d terms correspond to penetrating orbits. In complex spectra characterized by multiplet groups of lines Landé's formula appears to hold if the terms belong to a Rydberg sequence. C. C. KRESS

The absorption spectra and excitation stages of naphthalene and some of its methyl derivatives. HENRY G. DE LASZLO. *Z. physik. Chem.* 118, 369-414(1925).—A brief review of the theory of band spectra and a description of observations and measurements of the band spectra of naphthalene and some of its derivs. are given. The absorbing media were solns. in hexane and vapors in a heated quartz tube. The wave lengths observed are tabulated. Naphthalene as vapor and in soln. has an absorption spectrum of about 400 sharp narrow bands with fine structure between 3200 and 2820 A. U. in the ultra-violet and a group of broad continuous bands without fine structure between 2820 and 2500 A. U. Some of the fine-structure bands are arranged into P, Q and R, series. The moment of inertia of the mol. calcd. from the classical theory (3.45×10^{-40} g./sq. cm.) is far too small. It is suggested that the true moment of inertia is a multiple of this value and from the infra-red absorption spectrum a value 96×10^{-40} g./sq. cm. is derived. The absorption spectra of α - and β -methyl-naphthalene are displaced redward as compared with naphthalene, being more pronounced for the β -compd. than for the α -compd. The absorption bands of solns. in hexane are

more displaced than those of the vapors. The bands of the B-compd. are more numerous and more intense than those of the α -compd., some exhibiting fine structure. Other derivs. studied were 2,6- and 2,7-dimethylnaphthalene (*C. A.* 19, 1374). Of these the 2,6-compd. exhibited very strong bands. The effect of the CH_3 group on the absorption spectra is to cause a blending or fusion of the bands.

C. C. KIESS

Spectroscopic investigation of chemiluminescence. K. LILIKOV AND A. TERENIN. *Naturwissenschaften* 13, 83(1926).—The light emitted by the reaction $\text{I}_2 + \text{Na}$, K or Rb contains those lines of the alkali spectra of which the excitation energy is less than the heat of reaction, the first member of the series with the highest intensity. Also some bands were observed, probably corresponding to the fluorescence or absorption bands of alkali vapor. No emission, whatever, by the I_2 mol. could be detected, nor any "affinity" spectrum. The lines emitted were noticeably broadened, D_1 more than D_2 , showing that the emitting atoms have high speeds, due to excess kinetic energy as a result of the reaction.

B. J. C. VAN DER HOEVEN

Magnetic behavior of phosphors. E. RUPP. *Ann. Physik* 78, 505 7(1925), cf. Lenard, *Ann. Physik* 15, 425; *C. A.* 4, 1840; Schmidt, 15, 3246; Tomaschek, 19, 935.—The magnetic susceptibility, χ , is greater for the center mols. of the phosphor base, than for those of the unheated compd. Different bands of the same heavy metal added to the phosphor base arise from different valence combinations of this metal with the base. The absorption edge of Class I in Schmidt's nomenclature is due to trivalent combination; II to bivalent; and IV to a univalent combination. $\chi = A + B\theta + C/\theta$ where θ is abs. temp. ($290 < \theta < 570^\circ$) and $C/\theta = 0$ when θ is the temp. of the upper momentary state attained in prep. the phosphor. The paramagnetism of the whole center disappears when this temp. is exceeded. A phosphor whose time of phosphorescence had been reduced from 253 to 268 sec. by adding a trace of Fe showed an χ of -70 (original $\chi = -110$). Unexplained quant. relations between χ and the violet shift or doublet sepn. of the emission lines hold for the rare earth phosphors. χ does not change with the magnetic field strength in the range between 7000 and 20,000 gauss. χ for the heavy metal at. in the phosphor (and for a corresponding compd.) follows: $\text{CaMn}\alpha$, $\text{ZnMn}\alpha$, ZnMn , $+5.7 \times 10^{-4}$ (MnS , 3.86×10^{-3}); $\text{CaBa}\alpha$, -2.78×10^{-4} ($\text{Bi}(\text{NO}_3)_3$, $+1.14 \times 10^{-9}$); $\text{CaCu}\alpha$, -5.7×10^{-6} (CuS , -1.54×10^{-5} ; Cu_2S , -2.1×10^{-6}); $\text{SrAg}\beta$, -11×10^{-6} (AgI , -4.9×10^{-5}). In a well-formed ZnS phosphor, excited phosphor is more paramagnetic than the unexcited form. The magnetic moment of the bivalent Mn at. in a $\text{Mn}\alpha$ phosphor is 4.8×10^{-20} cm.²/g./sec.⁻¹ or 17 magnetons. R. proposes a model and explains various magnetic relations of the phosphor. Assuming spacial quantization, univalent Mn should have 6, bivalent 5 and trivalent 4 magnetons. A new method is developed to measure χ . A spherical phosphor grain is allowed to fall through a viscous liquid and its velocity with (ω_2) and without (ω_1) a magnetic field is observed. $\chi = \mp g(1 - \omega_2/\omega_1)/(H dH/dx)$.

D. S. VILLARS

Photocells and thermoelements. F. GOOS AND P. P. KOCH. *Physik. Z.* 27, 41-2 (1926).—A microphotometric study of photoelec. cells and thermopiles shows that the former are much more responsive to radiation since the inertia is less than the 10th power of the thermopile value.

H. R. MOORE

The photographic blackening law for homogeneous X-rays. W. BUSSE. *Z. Physik* 34, 11(1925).—Recently Jönsson (*C. A.* 18, 3537) has investigated the time-density curves for homogeneous X-rays and found, contrary to previous experimenters, that it is curved, even for small densities. B. has repeated the work of Glocker and Traub and others, using homogeneous X-rays, and finds, in agreement with previous results, that the Bunsen law holds up to densities of 0.6. He ascribes the results of Jönsson to the method of development used.

S. K. ALLISON

Active nitrogen. RICHARD RUDY. *J. Franklin Inst.* 201, 247-8(1926).—The decay of active N is bimolecular, but it takes a 100° rise in temp. to double the rate. A magnetic field of 500 gauss has no effect. The active modification is thought to be analogous to metastable Ne, which has a life of 0.004 sec. The afterglow in N is excited by about 11.4 v.

F. O. A.

The decomposition of nitrogen pentoxide and infra-red radiation. H. AUSTIN TAYLOR. *J. Chem. Soc.* 48, 577-82(1926).—No noticeable acceleration of the decompn. of N_2O_5 occurs in the presence of infra-red radiation between the limits 2μ and 8μ inclusive of the 2 absorption bands at 3.4μ and 5.8μ exhibited by the gas. A general discussion on the application of radiation to chem. reaction is presented with special reference to unimolecular reactions. The simple radiation theory would suggest a much larger decompn. of N_2O_5 than is actually observed.

MARIE FARNSWORTH

The photochemical inactivity of infra-red radiation with special reference to the

decomposition of nitrogen pentoxide. FARRINGTON DANIELS. *J. Am. Chem. Soc.* 48, 607-15(1926).—Infra-red radiation does not cause the photochem. decompn. of N_2O_5 . CO_2 , HCl gas or the oxidation of C_2H_5OH vapor. The sensitivity of the tests and the possible decompn., calcd. from the energy input, are critically discussed. At least 99 1/2% of the radiation actually absorbed is chemically inactive. There is a slightly increased decompn. at room temp. due to thermal effects, which disappears at 0°. The "radiation hypothesis" of chem. reaction is thus rendered improbable, for it is difficult to see how ordinary thermal reactions can be caused by radiation emitted by the walls of the contg. vessel, if the radiation itself is inactive. MARIK FARNSWORTH

4 -ELECTROCHEMISTRY

COLIN G. FINK

Electric furnaces show good results. ANON. *Elec. World* 87, 465 (1926). Two 250-lb. Detroit elec. furnaces are producing 25 heats in 18 hrs. A table shows that the total av. melting cost per ton is \$11.86 the production being about 50% brass and 50% phosphor bronze. In 1925 a 0.5-ton Pittsburgh elec. furnace was installed to melt charges of cast-iron scrap and steel turnings and punchings. From 12 to 14 heats are produced in 24 hr. The total av. melting cost is \$14.48 per ton when loose borings and turnings are used as the charge. It is expected that this cost will be lowered and be less than the purchase price of such castings. A. D. S.

Some new centers of electrochemical industry. II. Electrolytic alkali and chlorine J. B. C. KERSHAW. *Ind. Chemist* 2, 75-8(1926), cf. *C. A.* 19, 2783. E. H.

Carborundum production in Europe. ANON. *J. four élec* 34, 227(1925). A brief review of the history, properties and production, in some European factories. C. J. BROCKMAN

Induction brass furnaces save 30%. D. ST. PIERRE DU BOSE. *Elec. World* 87, 505(1926).—Each of 5 Ajax induction furnaces (4 of 100 kw. capacity and 1 of 125 kw.) is now provided with a transformer with 12 secondary taps so that the voltage successively applied to a new charge can be changed from 20 v. to 180 v. and finally to 320 v. when the furnace is poured the voltage is reduced to 95 v. The investment has resulted in a net saving of 30% over the previous cost of melting and a 50% reduction in labor. On an av. 24 heats are poured per furnace per 24-hr. day, 750 lbs. being poured at a time so that 400 lbs. of molten metal always remains in the furnace to complete the secondary loop; in other words the holding capacity of the furnace is 1150 lbs. The life of the one-piece cast lining is 3900 heats and both yellow and red brass are melted at an av. of 10 1/4 lbs. per kw. hr., or an av. consumption of 2000 to 2200 kw. hr. per furnace per day. A. D. SPILLMAN

Electrolytic deposition of cadmium and other metals on aluminum. C. H. DESCH AND E. M. VELLAN. *Trans. Faraday Soc.*, Feb., 1925 (advance proof), 2 pp.—For cleaning and prep. the surface of Al vessels previous to electroplating, sand blasting is most satisfactory; after this treatment the metal may be either plated with Cu for 1 min. in a cyanide bath and again sand-blasted or made the anode for 1/2 min., then the cathode for 1/2-1 min., in a soln. contg. 200 g. of $FeCl_2$ and 175 g. of $CaCl_2$ in 1 l. of water, and again sand-blasted. The most resistant deposits of Cd were obtained from an electrolyte made as follows: a satd. soln. of 100 g. of $CdSO_4$ in water is treated with NH_3 till clear, 3 g. of peptone are added and the soln. is diluted to 1 l. so as to contain 2.5% of free NH_3 ; the soln. is electrolyzed for 24 hrs. between an amalgamated Cd anode and a Cd cathode before use. For electroplating Al the same anode is used with a c. d. 5-7 amp. per sq. ft. The deposits do not peel off even on bending and resist the salt spray test for a few days and ordinary atm. conditions for many months. Al. thinly coppered, may be coated with quite thick deposits of Fe from ferrous NH_4 sulfate electrolytes and with Ni from the usual boric acid-Ni-sulfate-chloride bath. B. C. A.

The secondary reaction in the discharge of lead storage batteries. C. FÉRY and C. CHÉNEVEAU. *Compt. rend.* **181**, 606(1925).—F. and C. verify the reversible reaction of the Pb accumulator which F. previously presented (cf. C. A. **19**, 1099) by measuring the variation in wt. of the plates on charging and on discharging. A hydrostatic balance was used. Their results disagree with those of the theory of double sulfation. This they explain by considering the liquid of the battery as a satd. soln. of lead sulfate in acidulated water and that a secondary reaction: $\text{Pb} + \text{Pb}_2\text{O}_3 + \text{H}_2\text{SO}_4 = 2\text{PbO}_2 + \text{PbSO}_4 + \text{H}_2\text{O}$ takes place at the positive plate besides the reaction F. previously presented. They reject the theory of double sulfation. A. D. S.

The growth of the storage battery, 1882-1926. ANON. *World Power* **5**, 160-5 (1926). C. G. F.

Manufacture of iodine by electrolysis of its salts. L. PISSARIEVSKII AND S. TEL'NUI. *J. Chem. Ind. (Russia)* **1**, 13-5(1924).—In operating with acid solns. of I salts, I is deposited on the anode and seps. from it easily; the consumption of current is not much more than theoretical. The drawback to this method is that considerable quantities of I volatilize in the course of the operation. P. and T., therefore, recommend operating with neutral or slightly alk. solns. In the latter case, the alkali metals, which sep. on the cathode, react with water and become transformed into hydroxides; these, in turn, react with I, which has sepd. on the anode, to form iodide and iodate. When the stage is reached at which $\frac{1}{6}$ of the I in the soln. is transformed into iodate and $\frac{5}{6}$ of the I remains in form of iodide, the electrolysis is stopped, the electrolyte is poured into a bottle and acidified, whereupon I is pptd. according to the equation $6\text{H}^+ + 5\text{I}^- + \text{IO}_3^- = 3\text{I}_2 + 3\text{H}_2\text{O}$. Expts. show that in order to obtain 1 kg. of I it is necessary to use 1.7 kw. hrs. and about 228 cc. H_2SO_4 (d. 1.83). The presence of chlorides is not harmful, as the Cl sepd. by electrolysis merely displaces the equiv. amt. of I from its salts. H which seps. on the cathode decomposes the iodate formed and this results in an expense of current. To obviate this, the intensity of the current must be increased on the cathode and the cathode must be sepd. by a diaphragm, or by a glass tube. I obtained by electrolysis of ash lyes in acid soln. contained about 1% S; I obtained by electrolysis of the same lyes in alk. soln. contained practically no S and no Cl.

Refining aluminum or other metals electrolytically. D. H. TILSON. U. S. 1,572,253, Feb. 9. In putting an electrolytic cell into operation for refining Al or other metal, a layer of molten electrolyte, *e. g.*, mixed fluorides, is first established in the cell followed by 2 successive layers of molten metal of different densities, *e. g.*, an Al, Cu and Si alloy and Al. A crust from the electrolyte layer is congealed on the sides of the cell to form part of a side-lining before the second metal is established and the side-lining is afterward completed.

Copper from ore. W. E. GREENAWALT. U. S. 1,572,114, Feb. 9. A Cu soln. obtained by leaching Cu ore with an acid soln. is alternately subjected to the action of a reducing agent such as SO_2 and to electrolysis to deposit Cu and regenerate acid for further leaching. When the soln. becomes fouled with impurities from repeated use a portion of it is diverted to a sep. electrolytic circuit and its acidity is reduced and the diverted foul soln. is further subjected alternately to a reducing agent and to electrolysis. U. S. 1,572,115 relates to similar methods. App. is described. Cl. C. A. 19, 1400.

Alkali metal phosphates. C. M. HOFF. U. S. 1,572,846, Feb. 9. A soln. of Na_2HPO_4 or other alkali metal phosphate is electrolyzed in a diaphragm cell and the alkali metal phosphate contents of the anode and cathode liquors are separately recovered in order to obtain purified products such as NaH_2PO_4 and Na_3PO_4 .

Electric resistance conductors. NEDERLANDSCH TECHNISCHE HANDEL MAATSCHAPPIJ GIRO. Brit. 236,880, Feb. 5, 1924. Rods, bars, strips or layers are formed of hard or soft vulcanized rubber contg. finely powd. graphite.

Rectifiers and similar gaseous discharge devices with heated filamentary cathode. E. W. BREISCH. U. S. 1,572,882, Feb. 16.

Electrolytic condensers, rectifiers and lightning arresters. R. D. MERSHON. U. S. 1,572,403, Feb. 9. Heat liberated by internal elec. losses serves to produce boiling and agitation of the electrolyte.

Electric incandescent lamp. R. E. MYERS. U. S. 1,572,670, Feb. 9. Lamp bulbs are filled with H and are formed of lime glass (free from Pb) or other material resistant to the action of H so that blackening during operation is avoided.

5—PHOTOGRAPHY

C. E. K. MEES

New Buri process. ANON. *Camera (Luzern)* 4, 105-6(1925).—The Buri powder process, formerly suited only for making direct reproductions of positives, has now been modified to permit making prints from negatives. A gelatin-coated paper is soaked in H_2O , dusted with the color in powder form, sensitized with dichromate, exposed under the negative and developed either in soapy H_2O or in sawdust and H_2O . A positive in colored relief is thus produced. In making reproductions of positives, the gelatin coated paper is first sensitized with dichromate, then exposed under the positive allowed to swell in warm H_2O to produce relief and finally dusted with the powder, which is wiped off with a wad of cotton. The color is taken up more strongly by the less exposed portions, producing a direct positive. M. W. SEYMOUR

Emulsion color photography. W. EISSFELDT. *Phot. Ind.* 23, 1330-1(1925).—E. discusses the advantages and also the difficulties of his method of color photography according to which the color is produced after development by the oxidation of leuco dye bases with which the Ag halide grains have been treated. The method consists in separately sensitizing each third of a AgBr emulsion to one part of the spectrum, then, by a procedure not disclosed, bringing about the attachment to each of the leuco bases of a dye of the complementary color, mixing, washing, exposing, developing and fixing. The Ag of the image is then replaced by $\text{Cu}_2\text{Fe}(\text{CN})_6$, whereupon, after washing, the leuco bases become oxidized. AgBr when color sensitized retains its blue sensitivity

To overcome this serious disadvantage E. hopes that a substance may be found which will desensitize specifically for blue. A. P. H. TRIVELLI

Halation and halation prevention. J. RHEDEN. *Phot. Rund.* 63, 69-78(1926).—Halation may be caused either by reflection or diffusion or by both. The effect may be hindered to a large extent by using a red colored layer between the glass and the emulsion for ordinary or orthochromatic plates or a brown MnO_2 layer for panchromatic, which entirely prevents halation; by using a less sensitive $AgCl-AgBr$ emulsion between the glass and regular emulsion or by backing the plate with a suitable dark colored material which does not reflect the light and is removed in the developer or the fixing bath. Methods for measuring anti-halation properties are described and a table comparing the halation obtained with 48 varieties of plates and films is given. V. MOYES

Fogging action of hydrogen peroxide. W. CLARK. *Phot. J.* 66, 78-84(1926).—Single layer plates used in this research are liable to fog from handling in prepn. H_2O_2 action resembles that of light and accidental fog must be minimized. H_2O_2 may act directly or by way of chemiluminescence. In the latter case agents which engender decompn. of the soln. should increase fog, whereas fog is greatest in soln. stabilized by acid. C. investigates the fog given by H_2O_2 in the presence of catalase from potatoes, the decreased quantity deciding against the chemiluminescence theory. While the true mechanism still remains obscure previous suggestions concerning the interaction of H_2O_2 and a "hydroxide body" are found untenable. K. C. D. HICKMAN

Development with leuco bases. LÜPPO-CRAMER. *Phot. Ind* 23, 1329-30(1926).—L.-C. discusses E. O. Langer's expt. on the development of Ag halide emulsions with the leuco bases of phenosafranine, pinakryptol green and methylene blue. He points out that similar developing power with the leuco bases of malachite green, fuchsin and indigo had been described by Abribat. Neither Lumière and Seyewetz, nor L.-C. succeeded in observing any developing action by any leuco base, provided that the latter was free from impurities such as hyposulfite or $FeSO_4$. A. P. H. TRIVELLI

Investigations on the effect of desensitizers on sensitized plates. H. STAMM-REICH AND H. THÜRING. *Z. wiss. Phot.* 23, 363(1925).—S. and T. have examd. the action of 9 desensitizing dyes on ordinary (non-color sensitive), orthochromatic (erythrosin and pinaflavol bathed), and panchromatic (ethyl red and dicyanin bathed) plates. In all cases the greatest desensitizing action occurs in the ultra-violet and blue, and for each kind of plate tetramethylsafranine and Nile blue 2B are the most effective. Compared with the ordinary and orthochromatic, the panchromatic plates require the use of appreciably more concd. soln. of the desensitizing dyes. The dyes, methyl green, crystal violet, Nile blue, phenosafranine and others which desensitize ordinary plates, may, in certain concn. as Lüpbo-Cramer has observed for phenosafranine, actually increase the color sensitivity of orthochromatic or panchromatic plates. C. E. K. M.

Opalescence in spirit-dried negatives. J. I. CRABTREE. *Brit. J. Phot.* 72, 723(1925).—The opalescence frequently produced in negatives when dried with alc. has been attributed to various causes, including the use of alc. contg. rosin or naphtha, insufficient fixing or washing of the emulsion, the presence of Ca salts in the wash H_2O , etc. These factors may influence the amt. of opalescence produced but they are not the only detg. factors, since it is possible to obtain severe opalescence by immersing a film of plain gelatin free from lime in pure grain alc. and drying at $95^\circ F$. The amt. of opalescence produced is greater the more rapid the drying and the higher the temp. of drying; but, even if the film is insufficiently fixed and washed, opalescence rarely occurs if drying is conducted at $70^\circ F$. The opalescence is apparently due to a change of the gelatin by the alc. to a dehydrated modification which is also produced by adding alc. to a soln. of gelatin in warm H_2O . Hard gelatin is more readily pptd. than soft gelatin. J. I. CRABTREE

Imbibition printing. II. E. J. WALL. *Am. Phot.* 19, 668-76(1925); cf. C. A. 20, 154.—W. considers the character of the paper surface and the dyes best suited for imbibition printing. Directions are given for making the final transfer of the dyed image to the paper support. G. E. MATTHEWS

Desilverization of fixing baths. A. STEIGMANN. *Filmtechnik* 1, 316-7(1925); cf. C. A. 19, 1543.—Modification of the original hyposulfite method of Ag recovery of S. It is not necessary to make the recovery bath alk., and 5-6 g. of $Na_2S_2O_4$ with an equal wt. of anhyd. Na_2SO_3 are used for each l. of exhausted fixing bath. The value of the "hypo" recovered is greater than that of the $Na_2S_2O_4$ used. The use of a FeS gel is discussed as a Ag recovery material. J. F. ROSS

Electrically deflagrated mercury filament as a flash light for instantaneous photography. K. SUYEHIO. *Nagaoka Anniversary Volume, Tokyo 1925*, 23-7.—Elec-

trically deflagrated wires give flashes of long duration compared with those from Hg threads in narrow capillary tubes. The max. flash intensity resulted from 80 v. impressed on a 10 mm. filament of 0.324 mm. diam. The flash lasted less than $\frac{1}{1000}$ sec.
K. C. D. HICKMAN

Photomechanical printing surfaces. L. PEPE and D. DENAGY, Brit. 236,621, April 4, 1924. A coating which is sensitized with chromate comprises a hyaline gelatinous neutral soln. of lactic casein, legumin, gluten, fibrin or a combination of these substances prepd. in purified form. Details of purification and other treatment are given.

Polychromatic "security" print. R. LAMP'LE, U. S. 1,573,006, Feb. 16. Adjoining designs are printed in distinctive colors such as aniline green and aniline blue which produce about the same degree of blackness of the negative when they are photographed with and without color filters.

Photographic transfer processes for ornamenting sheet metal, stone, etc., in imitation of natural wood grain or other designs. L. G. NICOLL, Brit. 236,714 and 236,715, June 17, 1924.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

An electrometric and a phase rule study of some basic salts of copper. H. T. S. BRITTON, *J. Chem. Soc.* 127, 2796-2807 (1925).—Of the many basic sulfates and chlorides of Cu which have been reported, only 1 definite sulfate and 1 definite chloride exist at 25°, namely, $4\text{CuO} \cdot \text{H}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$ and $4\text{CuO} \cdot 2\text{HCl} \cdot 3\text{H}_2\text{O}$. Similar nitrate and bromide compds. are produced by pptn. with alkali under similar conditions, $4\text{CuO} \cdot 2\text{HNO}_3 \cdot 2\text{H}_2\text{O}$ and $4\text{CuO} \cdot 2\text{HBr} \cdot 2(?)\text{H}_2\text{O}$. The similarity in compn., form, color and the fact that they are pptd. from soln. at about $[\text{H}^+] = 10^{-8.6}$ seems to be due to an intrinsic property of either the Cu atom or the CuO mol. The constitution of these basic salts is discussed with reference to Werner's coördination theory. According to the manner of mixing and the quantity of alkali used, either apparently amorphous or gelatinous ppts. may be obtained by adding alkali to a soln. of CuSO_4 , CuCl_2 or CuBr_2 . Observations were made on the darkening of suspensions of basic Cu salts on boiling. The behavior of the $\text{Cu}|\text{Cu}(\text{OH})_2, \text{NaOH}$ electrode is erratic and the value of Jellinek and Gordon (*C. A.* 19, 1520) for $[\text{Cu}^{++}][\text{OH}^-]_2$ is untrustworthy. R. H. LOMBARD

The bromination of zinc in the presence of various organic solvents. A. RAYNAUD, *Compt. rend.* 181, 1069-71 (1925).—In continuation of expts. on the action of Br on metals in various liquids (cf. *C. A.* 8, 1712, 3288, 3437; 9, 787; 14, 2767) Zn and Br were kept in contact for 3 months at room temp. alone and in the presence of H_2O , Et_2O , C_6H_6 , CCl_4 , octane and petr.-ether. Only with H_2O and Et_2O did the Zn and Br react. With insufficient H_2O or Et_2O , the reaction ceased before completion, indicating in accordance with the view of Gautier and Charpy (*Compt. rend.* 113, 597 (1891)), that in the presence of Zn the H_2O or Et_2O is decompd. by the Br and that the ZnO is then transformed to ZnBr_2 by the HBr. With Et_2O , a viscous liquid was obtained which did not fume in the air and which decompd. above 110° with liberation of Et_2O . Likewise pure ZnBr_2 on digestion with Et_2O (the soly. of ZnBr_2 in Et_2O being about 45%) gave a similar liquid, which, however, on drying crystd. to white, deliquescent plates. In both cases analysis showed the product to be the compd. $\text{ZnBr}_2 \cdot \text{Et}_2\text{O}$. The results indicate that a solvent promotes the reaction of a metal and a halogen only when it dissolves both Br and the bromide formed and also forms an addn. product with the bromide. Also in *Bull. soc. chim.* 39, 195-201 (1926). C. C. DAVIS

A polarimetric study on organic and inorganic dimolybdomalates. An application of Oudemans' law. E. DARMOIS and P. GABIANO, *Compt. rend.* 182, 269-71 (1926). Previous investigations have shown that molybdic and malic acids are capable of formation of a complex anion. The Na and NH_4 salts have the formula $4\text{MoO}_3 \cdot 2\text{C}_4\text{H}_6\text{O}_6\text{M}_2 \cdot x\text{H}_2\text{O}$ (M being the alkali metal). Additional compds. were prepd. of Li, K, Ca, Ba, Cu, Ni, MeNH_2 , PhNH_2 , Et_3NH and *p*-toluidine. They contain varying amts. of water of crystn. The investigation of the rotatory power confirmed the law of Oudemans (constancy of mol. rotation). The polarization is due to the anion $[4\text{MoO}_3 \cdot 2\text{C}_4\text{H}_6\text{O}_6]^{IV}$. Similar conditions were found with the rotatory dispersion. EMIL KLARMANN

Complex molybdates with organic bases. CLARA DI CAPUA, *Gazz. chim. ital.* 55, 909-16 (1925).—It is known that in many cases it is possible to obtain in the form of complexes types of salts not stable in the simple form (Parravano, *Pasta, Gazz.* 37,

II, 252(1907)). Molybdates of bivalent metals with org. bases were prepd. in this way. On mixing a 0.5 *N* soln. of NH_4 molybdate with $\text{Co}(\text{NO}_3)_2$ and the calcd. amt. of $\text{C}_6\text{H}_5\text{N}$ a peach-red *cobalt pyridine molybdate*, $\text{MoO}_3 \cdot \text{CoO} \cdot 4\text{C}_6\text{H}_5\text{N}$, was pptd.; on washing this with EtOH and Et_2O it became a violet compd. $\text{MoO}_3 \cdot \text{CoO} \cdot 2\text{C}_6\text{H}_5\text{N} \cdot 2\text{H}_2\text{O}$; washed with $\text{C}_6\text{H}_5\text{N}$ and dried in the air it became $\text{MoO}_3 \cdot \text{CoO} \cdot \text{C}_6\text{H}_5\text{N} \cdot 2\text{H}_2\text{O}$; if washed with EtOH and Et_2O and dried in the desiccator it became $\text{MoO}_3 \cdot \text{CoO} \cdot 1.5\text{C}_6\text{H}_5\text{N}$. Thus from the original salt 3 others were derived. A similar mixt. treated with urotropine (Ur) gave a ppt. which was sol. in excess Ur. From this soln. a violet *cobalt urotropine molybdate*, $\text{MoO}_3 \cdot \text{CoO} \cdot \text{Ur} \cdot 2\text{H}_2\text{O}$, was sepd. which was washed with EtOH and Et_2O and dried in air. If the above soln. was kept at 0° a dark red easily sol. salt, $5\text{MoO}_3 \cdot 2\text{CoO} \cdot 2\text{Ur} \cdot 12\text{H}_2\text{O}$, sepd. which washed with EtOH and Et_2O gave $3\text{MoO}_3 \cdot \text{CoO} \cdot \text{Ur} \cdot 6\text{H}_2\text{O}$ (I); from the mother liquors a red salt, $5\text{MoO}_3 \cdot 2\text{CoO} \cdot 2\text{Ur} \cdot 12\text{H}_2\text{O}$ (II), sepd. which when washed with EtOH and Et_2O gave $3\text{MoO}_3 \cdot \text{CoO} \cdot \text{Ur} \cdot 6\text{H}_2\text{O}$. If the mixt. was prepd. at 25° a red ppt. sepd. which washed with EtOH and Et_2O and dried in the air gave $6\text{MoO}_3 \cdot 3\text{CoO} \cdot 2\text{Ur} \cdot 12\text{H}_2\text{O}$; from the mother liquors II was obtained and this on washing with EtOH and Et_2O gave $3\text{MoO}_3 \cdot \text{CoO} \cdot \text{Ur} \cdot 9\text{H}_2\text{O}$, a modification of I. A mixt. of 0.5 *N* Co and 2 *N* guanidine molybdate solns. at $35-40^\circ$ pptd. $12\text{MoO}_3 \cdot 12\text{CoO} \cdot \text{Gu} \cdot 22\text{H}_2\text{O}$ (Gu = guanidine). With twice as much Gu molybdate at $25-30^\circ$ $7\text{MoO}_3 \cdot 7\text{CoO} \cdot 2\text{Gu} \cdot 18\text{H}_2\text{O}$ sepd. From the mother liquors crimson red $2\text{MoO}_3 \cdot \text{CoO} \cdot 2\text{Gu} \cdot 4\text{H}_2\text{O}$ sepd. An excess of $\text{C}_6\text{H}_5\text{N}$ added to a soln. of NiCO_3 and MoO_3 at $15-20^\circ$ gave a pale blue salt, $\text{MoO}_3 \cdot \text{NiO} \cdot 5\text{C}_6\text{H}_5\text{N} \cdot \text{H}_2\text{O}$. Ur and Ni molybdate solns. did not crystallize at 0° ; at 15° a pale blue salt $8\text{MoO}_3 \cdot 3\text{NiO} \cdot 2\text{Ur} \cdot 36\text{H}_2\text{O}$ (III) sepd.; from the mother liquors a turquoise blue salt $8\text{MoO}_3 \cdot 2\text{NiO} \cdot 3\text{Ur} \cdot 16\text{H}_2\text{O}$ sepd. III is quite sol. in excess of Ni salt as well as in excess of Ur; from both solns. apple green $6\text{MoO}_3 \cdot 3\text{NiO} \cdot 2\text{Ur} \cdot 16\text{H}_2\text{O}$ sepd. Ni molybdate solns. with excess Gu molybdate sepd. $6\text{MoO}_3 \cdot \text{NiO} \cdot 5\text{Gu} \cdot 12\text{H}_2\text{O}$. MgCO_3 was dissolved in the calcd. amt. of MoO_3 and on treating with Ur sepd. $\text{MoO}_3 \cdot \text{MgO} \cdot \text{Ur} \cdot 10\text{H}_2\text{O}$. A similar soln. treated with $\text{C}_6\text{H}_5\text{N}$ gave $\text{MoO}_3 \cdot \text{MgO} \cdot 7\text{H}_2\text{O}$. When a 14% Ur soln. is added to a mixt. of MnSO_4 and $(\text{NH}_4)_3\text{MoO}_4$ a yellow powder, $3\text{MoO}_3 \cdot 2\text{MnO} \cdot \text{Ur} \cdot 5\text{H}_2\text{O}$, is pptd. A satd. soln. of Gu_3MoO_4 with 2 *N* MnSO_4 pptd. yellow $12\text{MoO}_3 \cdot 12\text{MnO} \cdot \text{Gu} \cdot 18\text{H}_2\text{O}$. Gu almost always gives products of complex compn.

L. J. WITZEMANN

Heavy metal vanadates and their ammoniates. EPHRAIM FRITZ AND GOTTFRIED BECK. *Helvetica Chim. Acta* 9, 38-51(1926).—Alkali-free vanadates of Ni, Co, Cu, Zn, Cd, Mn and Be were prepd. by the addn. of the metal sulfate to an acid Ba vanadate. BaSO_4 pptd. out, leaving the acid heavy metal vanadate in soln. This latter was crystd. out by concn. of the soln. or by addn. of alc. The compn. of the salts is $2\text{MeO} \cdot 3\text{V}_2\text{O}_5 \cdot 12$ or $15\text{H}_2\text{O}$. They lose their water of crystn. at 220° . When exposed to NH_3 for periods of several days, these compds. take up 6 mols. of NH_3 for each heavy metal atom. Digestion in liquid NH_3 increases the velocity of NH_3 absorption. The color changes are those observed in the formation of other hexammines, consequently true compd. formation and not adsorption is supposed to take place. The following compds. were also prepd.: $3\text{PbO} \cdot 2\text{V}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$; $2\text{CuO} \cdot 5\text{V}_2\text{O}_5 \cdot 5\text{H}_2\text{O}$; $3\text{SrO} \cdot 2\text{V}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$.

R. J. HAVIGHURST

Silicon-nitrogen compounds with bridging silicon. ROBERT SCHWARZ AND WALTER SEYAUER. *Ber.* 59B, 333-7(1926).—It has been reported by Besson (cf. *Compt. rend.* 110, 518(1890)) that Si_2Cl_6 forms an additive compd. with NH_3 having the formula $\text{Si}_2\text{Cl}_6 \cdot 10\text{NH}_3$. This finding could not be corroborated by S. and S., who observed a replacement of all Cl atoms by NH_3 . The reaction was carried out with liquid NH_3 . The compd. obtained represents a polymerization product of a *bisaminoiminosilane*, $(\text{Si}(\text{NH})(\text{NH}_2))_2$. At -10° NH_3 is split off and a polymeric product of *triminodisilane*, $\text{HN} \cdot \text{Si}(\text{Si}(\text{NH})\text{NH}_2) \cdot \text{NH}$, results. Both compds. are violently decompd. by air and hu-

midity with production of NH_3 . Water and alkali solns. produce H, the amt. of which directly depends upon the amt. of Si in the "bridge." Si_2Cl_6 reacts with PhMgBr , forming a mixt. of monosilane derivs. The fraction b₁₇ 166° was identified as *diphenyldichloromonosilane*.

EMIL KLARMANN

Hydronitric acid as product of desolvation of ammononitric, hydrazonitrous and ammonohydrazonitrous acids. Experimental formation of sodium trinitride by ammonolysis of sodium nitrate with sodium amide. A. W. BROWNE AND FRANK WILCOXON. *J. Am. Chem. Soc.* 48, 682-90(1926).—Hydronitric acid may be regarded not only as ammononitric acid, but also as hydrazonitrous or as ammonohydrazonitrous acid. NaNO_3 undergoes ammonolysis in contact with fused NaNH_2 , with formation of NaN_3 . At 175° , a yield as high as 65.7% has been obtained on the basis of the equation: $\text{NaNO}_3 + 3\text{NaNH}_2 = \text{NaN}_3 + 3\text{NaOH} + \text{NH}_3$.

R. J. HAVIGHURST

The reaction of boric acid on alkaline carbonates in solutions. B. L. VANZETTI *Gazz. chim. ital.* **55**, 939-44(1925).—In a previous paper (*C. A.* **19**, 2461) the slow decomposition of alk. carbonates by hot solns. of a weak acid like H_3AsO_3 was described. The expts. were repeated with H_3BO_3 and partly with H_2AsO_3 . In a 150-cc. flask a dil. soln. of Na_2CO_3 was treated with the calcd. amt. of As_2O_3 and heated to boiling, while H_2 was passed in at the rate of ≈ 60 bubbles per min. The H_2O vapor was refluxed into the flask, the gas was dried and the CO_2 absorbed and weighed. The absorption app. was changed rapidly at stated intervals. In this way the rate of CO_2 evolution was detd. The data with H_3AsO_3 confirmed the earlier results. Four series of expts. were done with H_3BO_3 . The decompn. of the carbonate is continuous in this case as with H_3AsO_3 and becomes practically complete. The fact that the process is absolutely continuous shows that the series of equil. during the decompn. is uninterrupted in the sense that there are no special conditions for the stable formation of any definite compd. in soln. H_3AsO_4 , H_3PO_3 , H_3PO_4 , H_2SeO_3 , H_2TeO_3 and H_2FeO_4 are to be investigated in a similar manner.

E. J. WITZEMANN

Production of arsenic subsulfide. Reduction of certain arsenic compounds by sodium hyposulfite. WALTER FARMER and J. B. FIRTH. *J. Chem. Soc.* **1926**, 119-25. When As compds. are reduced with $\text{Na}_2\text{S}_2\text{O}_4$ one product is As_2S_3 , contg. 12.7% S, insol. in colorless NH_4SH . In moderately acid solns. arsenious compds. yield ppts. of As_2S_3 but arsenic compds. yield ppts. approx. $\text{As}_2\text{S}_3 \cdot \text{As}_2\text{S}_5$ in compn., and only half as much As_2S_3 is pptd. Increase in acid concn. increases the amt. of As_2S_3 pptd. In alk. soln. pptn. takes place at the b. p. of the mixed solns. Compds. contg. 4-11% S were prepd. Arsenates give practically no ppt. The subsulfide is probably formed by the interaction of the arsenious compd. and the hyposulfite, whereas As_2S_3 is formed from $\text{Na}_2\text{S}_2\text{O}_4$ itself a decompn. product of the hyposulfite. This explains the formation in acid soln. of As_2S_3 . In no case is all the As pptd., the max. being 99.24% with 10 g. of hyposulfite for 1 g. of As_2S_3 and only 57.25% from arsenic solns.

M. O. LAMAR

Action of hydrogen fluoride on compounds of selenium and tellurium. I. Selenium dioxide. E. B. R. PRIDEAUX and J. O'N. MILLOTT. *J. Chem. Soc.* **1926**, 167-74.—When HF is passed over SeO_2 contained in a Pt bottle with inlet and outlet rapid absorption of HF takes place, the temp. increases and the SeO_2 liquefies. As much as 75% by wt. of the product may be HF. The colorless liquid fumes strongly but the fumes contain only HF. Cu is rapidly attacked but glass only slowly if H_2O is absent. Evapd. *in vacuo* over dehydrating agents a sirup is formed. From the colorless liquid, $\text{SeO}_2 \cdot 5\text{HF}$ may be sepd. by freezing or by distn. Metzner (*Ann. chim. phys.* **15**, (1898)) has prepd. analogous Te compds., using aq. HF. An oxyfluoride is unlikely on account of the order of the affinities of F and O for H.

M. O. LAMAR

Pyridine ferriformates. R. WEINLAND and LUDWIG ENGEL. *Arch. Pharm.* **264**, 33-45(1926).—The following complex derivs. were prepd. and characterized: Addn. of a cooled mixt. of $\text{C}_6\text{H}_5\text{N}$ (4.0) and 90% CH_2O_2 (5.1) to an aq. soln. of FeCl_3 (2.7 g. $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ in 10 cc. of H_2O) yields brown-red crusts, $\text{Fe}_3(\text{CHO}_2)_6(\text{OH})\text{Pyr}$ + $2\text{H}_2\text{O}$, by other very definite procedures the compds. $\text{Fe}_4(\text{CHO}_2)_6(\text{OH})_4\text{Cl}_2\text{Pyr}_6$, grayish green unstable, smelling persistently of $\text{C}_6\text{H}_5\text{N}$; $\text{Fe}_8(\text{CHO}_2)_{16}(\text{OH})_8(\text{ClO}_4)_3\text{Pyr}_{10}$, black in reflected yellowish green in transmitted light, stable; the similar Bz compd. $\text{Fe}_8(\text{BzO})_{16}(\text{OH})_8(\text{ClO}_4)_3\text{Pyr}_{12}$, grayish green powder, $\text{Fe}_6(\text{BzO})_{12}(\text{OH})_6(\text{ClO}_4)_2\text{Pyr}_4$; $\text{Fe}_3(\text{BzO})_6(\text{OH})_3(\text{CNS})\text{Pyr}$, orange-red powder; $\text{Fe}(\text{CHO}_2)_2\text{Cl} \cdot \text{H}_2\text{O}$, yellowish green powder, $\text{Fe}(\text{CHO}_2)_2\text{Br} \cdot \text{H}_2\text{O}$, brownish red powder. Constitutional formulas are presented.

W. O. E.

Observations on the ferro- and ferricyanides. N. TARUGI. *Gazz. chim. ital.* **55**, 951-75(1925).—Baudisch and Bass (*C. A.* **16**, 4137) considered the constitution of ferro- and ferricyanides which T. dealt with many years ago (*IV Congr. Intern. di Chim. Appl.* **1906**, 116). T. reviews the question of the constitution of Prussian and Turnbull's blue. Preps. of the former were obtained by treating $\text{K}_3\text{Fe}(\text{CN})_6$ with an excess of pure FeSO_4 . The product was washed with H_2O to eliminate sulfate and dried in an oven to const. wt. From numerous analytical data obtained with such preps. and without reference to any theoretical point of view, it was found in all the blues examd. that a percentage of O is present that cannot be attributed to analytical error. This result was confirmed in various ways and with analytical procedures of abs. exactness and with reciprocal control. These results make it probable that none of the blues that arises from ferrocyanide and Fe^{+++} salts or from ferricyanides and Fe^{++} salts is derived from the hypothetical acids of B. and other authors.

E. J. WITZEMANN

The action of hydrogen sulfide on a neutral solution of potassium permanganate. H. B. DUNNICLIFF and S. D. NIJHAWAN. *J. Chem. Soc.* **1926**, 1-7.—If H_2S is passed into a soln. of KMnO_4 the products formed are colloidal hydrated MnO_2 (which later

coagulates), S, K_2SO_4 and $K_2S_2O_8$. An excess of H_2S leads to the pptn. of MnS . At the same time $K_2S_2O_8$ is changed to K_2SO_4 and S is pptd. Not all the S is pptd. at once, that in colloidal soln. seps. only on standing. M. O. LAMAR

Action of phosgene on beryllium oxide. Preparation of beryllium chloride. C. MATIGNON AND J. CATHALA. *Compt. rend.* **181**, 1066–8 (1925).— $COCl_2$ is a particularly valuable agent for prepg. volatile chlorides from oxides and is preferable to S_2Cl_2 (cf. M. and Bourion, *Ann. chim.* **5**, 127 (1905)) under such conditions. With BeO the yield increases both with increase of temp. and with increase in the velocity (pressure) of the current of $COCl_2$. The reaction becomes appreciable at about 350° and is fairly rapid at 1000° . In doubling the rate of the $COCl_2$ current, the rate of the reaction is increased to a degree depending upon the temp., but which is roughly 1.5 times. The results indicate that in the prepn. of chlorides by this new method, as high a temp. as practicable should be chosen. C. C. DAVIS

The action of sodium hypophosphite on stannic chloride. A. TERNI AND C. PADOVANI. *Atti accad. Lincei* [6], **2**, 501–5 (1925).— H_3PO_2 and alk. hypophosphites react with solns. of heavy metal salts in 3 ways: (1) Reduction of salts of max. soly. to salts of min. soly., e. g., $CuCl_2$ and $HgCl_2$ to $CuCl$ and $HgCl$, resp. The reduction may go further to the formation of the free metal. (2) Reduction to the free metal may take place directly as with Bi, Sb and Au salts or through intermediate compds. as Cu hydride and Ag hypophosphite which when slightly heated sep. the metal. (3) The formation of a stable and insol. hypophosphite, which is sometimes sol. when heated as in the case of Pb. T. and P. studied the action of alk. hypophosphites on $SnCl_4$. When dil. solns. were used no visible action occurred. With concd. solns. of hypophosphite and with pure $SnCl_4$ or dild. with an equal vol. of H_2O a white ppt. of a complex (I) $SnCl_4 \cdot Sn(H_2PO_2)_4 \cdot 3H_2O$ is formed which was washed with $EtOH$ and Et_2O . I is completely insol. in common solvents; it is sol. in cold HCl but only in hot H_2SO_4 . Washed with H_2O it hydrolyzes and may lose all Cl without, however, giving a product of const. compn. I is decompd. by HNO_3 , giving metastannic acid. It is easily sol. in alk. sulfides and in solns. of $(NH_4)_2C_2O_4$. I has the reducing properties of a hypophosphite. I is easily dehydrated at 140° , but at 100° only 1 mol. H_2O is lost. At 190° I decomp. with the evolution of PH_3 . In the decompn. by heat the mass becomes red. If heating is interrupted at this time and the mass taken up with concd. HCl a red substance is sep'd., which was filtered off, washed with abs. $EtOH$ and dried *in vacuo* over H_2SO_4 . This compd. having extraordinarily strong reducing power for metallic salts reacts with great avidity with H_2O_2 . It gives PH_3 with alkalis. In HNO_3 it is ignited with a bright flame. It contains 88.57% P and in all its properties corresponds to P_4O . E. J. WITZEMANN

Purification of phosphoric oxide. G. I. FINCH AND R. P. FRASER. *J. Chem. Soc.* **129**, 117–9 (1926).—A 36×2 -in. inclined Fe pipe with a 2.25-in. opening 12 in. from the upper end, to which is attached a 2-in. rounded delivery elbow, comprises the app. in which the sublimation is carried out. A current of O at the rate of 3 l. per min. is maintained through the tube. The charges of P_2O_5 are introduced into the bright-red-hot tube by removing the cap-cover of the 2.25-in. opening. The P_2O_5 rapidly sublimates and is caught in a wide-mouth glass bottle closely fitted to the receiver end. The app. produces 500 g. per hr. of P_2O_5 5 times as bulky as ordinary P_2O_5 . M. O. LAMAR

Studies in the chemistry of hydrogen. II. The systematization of the solid metal-hydrogen compounds. G. F. HÜTTIG. *Z. angew. Chem.* **39**, 67–75 (1926); cf. *C. A.* **19**, 2593.—H may be combined as electropositive, as metallic and as electronegative H. The H compds. of the elements vary in their general characteristics depending on the position of the element in the periodic table. The groups contg. the elements related to C, N, O and F form stable gaseous hydrides of definite chem. compn. This tendency of H to behave as an electropositive element reaches its max. in the halogen group. With most of the metals, such as Al, Mg, Cr, Mn, Fe and the related elements, H forms metallic hydrides which have the characteristics of alloys or solid solns. This tendency of H to function as a metal reaches its max. in the elements of the Ni-Pd-Pt groups, particularly Pd. These combinations do not have a definite chem. compn. but vary continuously. From extensive studies of the equil. pressure of H in such systems there are many conflicting data. It appears that the atoms of H have no definite location with reference to the space-lattice of the metal but that they move freely within the lattice. The compds. of H with the alkali metals partake more of the nature of salts, where H functions as an electronegative element. This characteristic reacifies its max. in the compd. with Li. These compds. again may have definite compns. corresponding to the ordinary stoichiometrical relations, though they sometimes deviate. The more important generalizations are: (1) The affinity of an element for H is less,

the further removed the element is from the column of max. H affinity. (2) The relations expressed by stoichiometric formulas correspond to ideal limiting cases. The metallic compds., and to some extent the salt-like compds., differ from the ideal to a measurable extent, so that in the former case stoichiometric relationships are almost unknown. (3) If, in a H compd., the atoms of one component have great mobility and the atoms of the other component slight mobility, such a system approaches the limiting case where the atoms of the one move within the atoms of the other in a manner corresponding to the osmotic diffusion law. The quantity of the freely moving atoms may vary within definite limits. (4) Between the different methods of combination of H, there is an equil. so that the different types gradually merge into one another. There is an extensive bibliography.

S. MORGULIS

Some rules with respect to the use of normal solutions prepared from "fixanal" substances. W. BÖTTGER. *Oesterr. Chem.-Ztg.* **29**, 4-6 (1926).—Since the caustic alkali used in "fixanal" tubes is not absolutely free from carbonate, the titer is not exactly the same against phenolphthalein as against methyl orange. In diluting, moreover, CO₂-free water should be used and on standing the NaOH attacks glass so that the titer changes. Since ordinary distd. water contains substances that reduce KMnO₄, only water that has been distd. with KMnO₄ should be used in KMnO₄ work. In short, unless great care is taken in the use of "fixanal" standards, the same effects will be produced that occurred before "fixanal" tubes were used and to overcome which was one of the advantages claimed for these standards.

W. T. H

The potentiometric standardization of titanium trichloride solutions. I. AL KOLTHOFF, O. TOMÍČEK and CONMAR ROBINSON. *Z. anorg. allgem. Chem.* **150**, 157-62 (1926); cf. *C. A.* **19**, 449. —K₂Cr₂O₇ is very suitable for standardizing TiCl₃ solns. but when near the end point it is advisable to add a little CuSO₄ to accelerate the reaction. The standardization of TiCl₃ against Cu⁺⁺ is not satisfactory as the e. m. f. jump at the end point is not very marked and the titer obtained is always a bit low. In the presence of thiocyanate ions, the results are better in both respects but even then CuSO₄ is not entirely satisfactory as a standard.

A new indicator principle in acidimetry and alkalimetry. Turbidity indicators. KARL NAEGELI. *Kolloidchem. Beihefte* **21**, 305-411 (1926).—Certain very weak organic acids are quite insol. in water but dissolve readily in dil. alkalies. When acid is added to the alk. soln. of the salt, a turbidity results at a definite concn. of the H ion. It is, therefore, possible to use such substances as indicators in acidimetry and alkalimetry and in some respects the results are better than with the ordinary indicators. In this thesis the theory governing the use of org. colloids as indicators is discussed in great detail and a bibliography of over 250 papers is appended. Particular attention is paid to the titration of substances of very low acidity such as boric acid, arsenious acid, phenol, *p*-chlorophenol, glycine, asparagine, veronal, alanine, leucine and tyrosine where the end point is in the neighborhood of $p_H = 11$ and many of the results obtained were

remarkably good. Six substances are mentioned as possible indicators of this type but the work described was done almost entirely with isonitrosoacetyl-*p*-aminoazobenzene and isonitrosoacetyl-*p*-toluenazo-*p*-toluidine. The results obtained in these indicators are altogether reproducible. The effects of practically all substances or conditions likely to cause trouble were carefully studied. The colloidal-chemical properties of the ppts. were studied, with the surprising result that they were found to be cryst. in nearly every case.

W. T. H.

The equilibrium between metal chloride, hydrogen sulfide, metal sulfide and hydrochloric acid and separations based upon it. Experiments with cadmium, bismuth and lead. W. MANCHOT, G. GRASSI AND A. SCHNEEBERGER. *Z. anal. Chem.* 67, 177-95 (1925).—Contrary to what might be expected from the title of this paper, no attention is paid to the mass-action law, soly.-products, or permissible use of significant figures. H_2S was introduced into 110 cc. of solns. contg. 0.223 g. of Cd with varying amts. of HCl until there was no indication of further pptn. Sometimes the CdS did not begin to form until after 5 days and sometimes 16 days was required to complete the pptn. It was found that a soln. contg. 10 g. HCl in 100 cc. would not give a ppt. of CdS when satd. with H_2S but one contg. 5 g. HCl would give complete pptn. Between these limits lies a field in which the pptn. is incomplete. If a soln. of $HgCl_2$ and $CdCl_2$ contg. 19 g. HCl per 100 cc. is satd. with H_2S , all the Hg will be pptd. and no Cd, provided the ppt. is washed with acid of the same concn. If 100 cc. of soln. contg. $SbCl_3$, $CdCl_2$ and 8 g. of HCl is satd. with HCl at the temp. of a boiling water bath, then dild. with 100 cc. of water and again satd. with the gas, all of the Sb is pptd. in about 40 min. and no Cd. In the case of Bi, all of 0.6 g. Bi in 100 cc. is pptd. when as much as 14 g. of HCl is present and none if 16 g. HCl. On the basis of this result, it is clear that the region of partial pptn. is much narrower than in the case of Cd and it is much more difficult to keep the Bi in soln. If, however, a soln. contg. about 0.1 g. of Bi and Hg in the presence of 18 g. HCl is dild. to 100 cc. and satd. with H_2S , all the Hg is pptd. and the HgS can be washed free from Bi with acid of the same concn. Pb can be sepd. from Hg in the same way as Cd from Hg. No attention is paid to the effects caused by other anions and cations in soln.

W. T. H.

Volumetric determination of iron in hydrochloric acid solution. W. MANCHOT AND F. OBERHAUSER. *Z. anal. Chem.* 67, 196-7 (1925).—To the Fe soln. reduced to the ferrous condition by H_2SO_4 , electrolytic Cd, or otherwise, add about 1 g. of KF and 20 cc. of 15% HCl or H_2SO_4 . Add a measured excess of 0.1 N Br in N KBr and after 2 min. add a slight excess of standard arsenite soln. and titrate this last excess with Br soln. Instead of KF, enough H_3PO_4 can be added to make the soln. contain 2-10% of this acid. Instead of the Br soln. a standard soln. of $KBrO_3$ can be used, it being then necessary to add about 2 g. KBr to the soln.

W. T. H.

The accurate determination of ferrous iron in insoluble silicates. O. HACKL. *Z. anal. Chem.* 67, 197-204 (1925); cf. C. A. 19, 3073.—Owing to the difficulty in detg. ferrous Fe in silicates, it was thought possible that the oxidation of the bivalent Fe by the atm. and the resulting error might be obviated if the treatment with HF was made to take place in the presence of some oxidizing agent such as $K_2Cr_2O_7$ and then the excess of dichromate detd. by titration. Circumstances have prevented the completion of the expts. but certain facts have been ascertained which will be of interest to any one else attacking the problem. It was found that ferric Fe is pptd. quant. by NH_4OH even in the presence of excess fluoride; pptn. of $Fe(OH)_3$ in the presence of chromate causes some chromate to be pptd.; pptn. of $Fe(OH)_3$ by adding K_2CO_3 does not cause appreciable co-pptn. of Cr even when considerable HF is in the soln.

W. T. H.

Ammonium oxalate, a reagent for distinguishing between potassium and sodium salts. J. MEYERFELD. *Z. anal. Chem.* 67, 150-1 (1925).— $Na_2C_2O_4$ is much less sol. in water than is $K_2C_2O_4$. The former salt ppts. when a satd. soln. of $(NH_4)_2C_2O_4$ is mixed with a satd. soln. of NaCl.

W. T. H.

Detection of titanium and of uranium by means of "spot" tests. N. A. TANANAEV AND G. A. PANCHENKO. *Z. anorg. allgem. Chem.* 150, 163-6 (1926).—If a drop of Ti sulfate soln. is brought into contact on filter paper with a drop of dihydroxynaphthalenedisulfonic acid soln. an intense brown coloration is obtained which serves to detect 0.005 mg. TiO_2 in a drop. The color is a little weakened by addn. of $SnCl_2$, which reagent prevents interference by Fe^{+++} or UO_2^{++} . For UO_2^{++} a suitable test is the ferro-cyanide reaction. To test for Ti and U in the presence of one another, a suitable soln. can be obtained from an ore by fusing with $K_2S_2O_7$ and extg. with a little water. • Neutralize a drop of the soln. with NH_4OH and add a drop of Na_2S soln., mix with an excess of concd. $(NH_4)_2CO_3$ soln. and filter. $Ti(OH)_4$, together with various sulfides, will be on the filter and the U will pass into the filtrate. Moisten a filter paper with the filtrate and

then with a drop of ferrocyanide soln. To test for Ti, add some SnCl_2 to the original soln., warm gently and transfer a drop of the clear soln. to a filter paper that has been touched with dihydroxynaphthalenedisulfonic acid soln. Other methods of applying these tests are also given.

Set of borax bead standards. E. R. CALEY. *J. Chem. Education* **3**, 189-90 (1926).—Directions are given for making and preserving a set of typical borax beads for use in qual. analysis.

The reaction of amide formation with mercurous salts. F. FRIGL AND A. SUCHARIPA. *Z. anal. Chem.* **67**, 134-40 (1925).—In the reaction between Hg_2Cl_2 and NH_3 , it seems likely that $\text{Hg}-\text{Cl}$ is formed first which changes slowly into

Determination of nickel as nickel dioxide. LUDWIG MOSER AND WLADIMIR MAXY MOWICZ. *Z. anal. Chem.* **67**, 140-2 (1925).—Vaubel (*C. A.* **17**, 249) made the astonishing statement that ignition of hydrated nickelic oxide yielded NiO_2 . A series of expts. confirms the view previously held that ignition of $\text{Ni}(\text{OH})_2$ yields chiefly NiO . There is some higher oxide present, probably Ni_2O_3 .

Notes on qualitative analysis. I. The volatility of the compound formed when barium sulfate is treated with concentrated sulfuric acid. F. KRAUSS. *Chem.-Ztg.* **50**, 33 (1926).— BaSO_4 on a Pt wire gives very little, if any, coloration in the Bunsen flame. The green Ba flame is obtained, however, if the BaSO_4 is moistened with HCl , but a still better flame test results by adding concd. H_2SO_4 . If BaSO_4 is moistened with concd. H_2SO_4 , heated, cooled and covered with methanol, then, on carefully heating and bringing near a Bunsen flame, the Ba flame test is obtained without the alc. taking fire. If BaSO_4 in a small tube is covered with concd. H_2SO_4 and then an air stream is passed through the tube and directed against a flame, a distinct green coloration results which is stronger if methanol is added to the reaction mixt. These 3 expts. show that the $\text{BaSO}_4\cdot\text{H}_2\text{SO}_4$ compd. is noticeably volatile and the Ba test is likely to interfere with the flame test for H_2BO_3 more than has ordinarily been supposed.

The influence of citrates on the precipitation of barium sulfate. M. L. NICHOLS AND O. J. THIES, JR. *J. Am. Chem. Soc.* **48**, 302-9 (1926).—It has been known for nearly 70 years that the presence of alkali citrate interferes with the pptn. of BaSO_4 and it was thought that a sol. double salt is formed. The present investigation makes clear that BaSO_4 is peptized by citrate anions so that it remains in colloidal soln. The colloidal BaSO_4 is in an extremely fine state of subdivision. If it is desired to ppt. BaSO_4 in the presence of citrate, it is advisable to add, at the start, somewhat more than sufficient HCl to convert the citrate anion into citric acid. Then a satisfactory ppt. of BaSO_4 can be obtained.

The determination of calcium by the conversion of the oxalate to carbonate. H. W. FOOTE AND W. M. BRADLEY. *J. Am. Chem. Soc.* **48**, 676-8 (1926).—Fresenius always recommended weighing Ca as CaCO_3 after pptn. as CaC_2O_4 but lately chemists have preferred igniting strongly and weighing as CaO . If the oxalate is heated to a temp. of $675-800^\circ$ for 15 min. in a current of CO_2 , it is changed completely to CaCO_3 and it is not necessary to moisten the mass with concd. $(\text{NH}_4)_2\text{CO}_3$, as in the classic method of Fresenius. A porcelain Gooch crucible covered with a Rose crucible lid and resting in a smaller porcelain crucible, which is heated with the full flame of a Bunsen burner, is suitable for maintaining the proper temp. The ppt. should be heated slowly until it is perfectly dry. This method is accurate and more rapid than the method of weighing as CaO .

Standardization of the analysis of zinc ores. ANON. *Rev. universelle mines* [7], **8**, 307-15 (1925).—The procedure for detg. Zn recommended by the Belgian Association of Standardization is given in complete detail. This is based on the method of Schaffner (1855), whereby the Zn is pptd. in NH_4OH soln. by aq. Na_2S of known concn with PbCO_3 as indicator.

Determination of free calcium ions by the method of Brinkmann and van Dam. HANS SCHULTEN. *Biochem. Z.* **164**, 47-52 (1925).—In the method of Brinkmann and van Dam Na oxalate is added in varying amts. to a soln. of CaCl_2 and the first resulting turbidity is noted at the end of 30 min. The soly. product of CaC_2O_4 is, therefore, 0.056, i. e., the same value as was found by Kohlrausch by his elec. cond. method. S. criticizes this procedure on the ground that under the exptl. conditions a supersatn. really is produced, the agreement by the turbidometric and electrometric methods being due to the fact that both are affected by the same source of error. He, therefore, proposes a modification of the original method to avoid this error, which consists in titrating the

Na oxalate with the unknown Ca^{++} soln. until the turbidity just disappears. By this method supersatn. is avoided, but the method is encumbered with serious technical difficulties.

S. MORCULIS

The determination and separation of rare metals from other metals. VI. Determination of the solubility of complex cesium and rubidium compounds and their suitability in analytical reactions. LUDWIG MOSER AND ERICH RIETSCHEL. *Monatsh.* 46, 9-22 (1925); cf. *C. A.* 19, 2180-1.—The sensitiveness of the reactions between Cs and Rb ions and the following reagents was detd. and values for the soly. of each ppt. obtained were: HClO_4 , $\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OK}$, $\text{Na}_3\text{Co}(\text{NO}_2)_6$, $\text{NaHC}_4\text{H}_4\text{O}_6$, SbCl_3 , SnCl_4 , SnBr_4 , BiCl_3 , Na silicomolybdate, and phosphotungstic acid. The ppts. may be classified into 3 groups: (a) those of perfectly definite compn., (b) complexes of more or less indefinite compn. and (c) insol. ppts. which are likely to be more or less hydrolyzed so that a definite compd. can be obtained only at certain H^+ concns. The perchlorates, picrate and bitartrates belong to the first class and can alone serve for quantitative work except perhaps under very narrow conditions. The picrates are the least sol. but the soly. of these Cs, Rb and K salts are practically identical. There appears to be no truly sp reagent for either Cs or Rb ions. The most reliable test for them in the presence of K is the test with silicomolybdic acid, although the reaction with SnBr_4 can serve this purpose. For the detection of Cs and Rb, the test with phosphotungstic acid is the most delicate and next comes that with $\text{Na}_3\text{Co}(\text{NO}_2)_6$.

W. T. H.

A new method for separating iron from mercury. GEORG SPACU. *Z. anal. Chem.* 67, 147-50 (1925).—If a mercuric salt is treated with thiocyanate and pyridine in excess, a complex Hg compd. is obtained which remains in soln. but a ferric salt subjected to the same treatment is completely pptd. as $\text{Fe}(\text{OH})_3$. To 100-150 cc. of a dil. soln. contg. Hg and Fe, add 3-4 times as much solid KCNS as the combined wt. of Fe and Hg in soln. To the dark red soln. add pyridine dropwise until the color changes to yellowish brown. Add 3-4 drops of pyridine in excess, heat to boiling, filter and wash with hot water. Ignite the ppt. and weigh as Fe_2O_3 . To the filtrate add HCl, ppt. with H_2S and weigh the HgS. If HNO_3 is present in the original soln., evap. to dryness and dissolve the residue in water.

W. T. H.

New methods for determining copper, arsenic and mercury. RICH. ROSENDAHL. *Chem.-Ztg.* 50, 73-4 (1926).—For the As detn. in metal, dissolve 5 g. in HNO_3 , fume with H_2SO_4 and add 12 N HCl until the soln. is 6 N in HCl. If considerable Cu^{++} or Fe^{+++} is present it is advisable to reduce first with SnCl_2 . Add 5 g. NaH_2PO_4 and heat for 30 min. at about 85° . Cool, filter off the As and wash well with water. Place the ppt. and filter in a beaker contg. pure FeCl_3 and 50 cc. of concd. HCl. Boil 10 min., add 50 cc. more of concd. HCl and repeat the boiling to distil off AsCl_3 . Finally add sufficient MnSO_4 titrating soln. and titrate the ferrous salt (formed by the reduction of the As) with KMnO_4 in a vol. of 750 cc. All metals except Hg can be present. Ores, slags, etc., can be fused with Na_2O_2 and the aq. ext. acidified with HCl after boiling till all peroxide is decompd. It is also possible to dissolve the pptd. As in HNO_3 and evap. to fumes with concd. H_2SO_4 . Then by heating for 20 min. with about 1 g. of S, all the As can be reduced to the trivalent condition and, after dilg. and boiling off SO_2 , the soln. can be titrated with I_2 in the presence of NaHCO_3 ; but it is better, after boiling off SO_2 , to dil. to 250 cc., add 122 cc. of concd. HCl and a known amt. of antimonious salt soln. and titrate with KMnO_4 . The presence of Sb apparently catalyzes the oxidation of the As. To det. Cu, dissolve in HNO_3 if a metal, or fuse with Na_2O_2 if an ore. Fume with H_2SO_4 in the first case and make acid with H_2SO_4 in the second. Dil. with water, boil a few min., make slightly ammoniacal, add 6-7 g. of tartaric acid, 5 g. of NaH_2PO_4 and boil at least 20 min. Filter off the Cu and wash with water which has been freed from air by boiling. Dissolve the Cu on the filter with a soln. of HCl and FeCl_3 and titrate the resulting Fe^{++} by the Zimmermann-Reinhardt method. About 2 mg. of Cu are not pptd. by the NaH_2PO_4 so that a correction must be made. To det. Hg, dissolve in HNO_3 , evap. with H_2SO_4 and heat with S to reduce any quinquivalent As. Dil. with 20 cc. of water, add 50 cc. of concd. HCl and boil 10 min. to remove AsCl_3 . Dil. with water, add 5 g. NaH_2PO_4 and boil until the soln. is clear. Decant off the liquid, wash the Hg with water, dry and weigh as such.
